Release Notes 2.1.5

Confluence 2.1.5 is a maintenance release that resolves some issues users may have encountered using Confluence 2.1.4 or earlier. Confluence 2.1.5 fixes around 50 issues, including a number of fixes for LDAP support, the WYSIWYG editor, and other areas. 2.1.5 is a free upgrade for all customers who purchased their Confluence license after March 16th, 2005.

Confluence 2.1.5 has a problem which disables the rich text editor link dialog. Please replace the file WEB-INF/classes/com/atlassian/confluence/user/actions/PagePickerAction.properties with this file:

```properties
PagePickerAction.properties

This is fixed in 2.1.5a.

Known Issues in 2.1.5a

Anonymous users may get a Javascript error under some circumstances. See CONF-5765 for details and a patch.

When using LDAP user management, changing passwords for local users won't work. See CONF-5775 for details and a patch.

Who should upgrade?

Confluence 2.1.5 fixes a number of bugs found in Confluence 2.1.4 and earlier. Customers are recommended to upgrade if they are experiencing any of the issues fixed in this release.

Confluence is a recommended upgrade for all customers using Confluence's new atlassian-user LDAP user management, as it fixes important issues related to LDAP integration.

Upgrade Procedure

Upgrading Confluence should be pretty easy. If you are upgrading from an earlier Confluence 2.1 release, you can find instructions here. We strongly recommend that you backup your confluence.home directory and database before upgrading!

If you are upgrading from Confluence 2.0.3 or earlier, please check the release-notes of the other major Confluence releases:

- Release Notes 2.1
- Release Notes 2.0
- Release Notes 1.4
- Release Notes 1.3
- Release Notes 1.2
- Release Notes 1.1

Changes in 2.1.5

More than 48 issues were resolved between 2.1.4 and 2.1.5. For the complete list, see: Issues resolved for 2.1.5

Improvements

- LDAP queries are cached to improve performance - CONF-5288
- Administrators can insert custom HTML on every Confluence page, see Administration, Custom HTML - CONF-5350
- Tables created in the rich text editor don't have non-breaking spaces added to each cell - CONF-5044
- News improvements - Info tab available including list of version, News can be exported as PDF - CONF-1989, CONF-5582, CONF-5594

Notable Bugs Fixed

- Anchor, user profile and attachment links now round-trip properly in the rich text editor - CONF-5678
- Paging of LDAP users works properly - CONF-5438
- Servlet plugins can be disabled - CONF-5598
- Forgotten username emails work again - CONF-5530
- User profiles fixes with LDAP - CONF-5225, CONF-5549

Issues resolved for 2.1.5

Errors were reported by the JIRA trusted connection.

</table>
Atlassian is proud to announce the release of Confluence 2.2, otherwise known as Shoalhaven. Existing customers who wish to upgrade, or new users who wish to try out Confluence for 30 days, can download Confluence from the Atlassian website:
http://www.atlassian.com/software/confluence

Shoalhaven is the seventh major update to Confluence (in two years!). It introduces 'personal spaces', support for localisation/internationalisation, CAPTCHA spam protection, a multitude of new extension points for plugin developers, a simpler LDAP configuration syntax, and more.

**Upgrading from 2.1**

Upgrading Confluence should be pretty easy: you can find instructions here. We strongly recommend that you backup your confluence.home directory and database before upgrading!

- **MySQL Driver Support**
  For users using MySQL with Confluence 2.2 (or higher), please ensure that you are using the latest (3.1.12) MySQL Java Connector. Earlier versions of the MySQL connector have a bug which may prevent Confluence from upgrading successfully. (more information below)

- **LDAP Authentication**
  If you are currently using LDAP authentication through OSUser (that is, you adjusted your osuser.xml file), please do not upgrade to 2.2. This feature is currently unavailable and an issue has been filed for it here. This issue has been resolved in Confluence 2.2.1.

- **User Management Bug**
  You must apply the patch attached on this bug report to be able to create users in this version. This issue has been resolved in Confluence 2.2.1.

- **Index Rebuilding**
  Upgrading to 2.2 will trigger a rebuild of Confluence’s search index. This will cause certain features such as search, the dashboard and RSS feeds to behave unpredictably for up to a few minutes after upgrading.

- **LDAP Integration Configuration Changes**
  The configuration file syntax for atlassian-user has changed. Customers who configured Confluence 2.1 to use AtlassianUser LDAP integration must follow the instructions on this page.

- **Anonymous Permission Changes**
  The way that anonymous permissions are applied to users who have logged in has changed. Administrators should understand how they have changed before upgrading.
Plugin Loading Changes

Prior to Confluence 2.2, it was possible for an outdated plugin, or a plugin with unsatisfied dependencies, to break the entire plugin subsystem. Confluence 2.2 is much more careful about loading plugins, and isolating them if they break. This may, however, cause Confluence to refuse to load an entire plugin, simply because one of its contained plugin modules will not load.

Upgrading from 2.0 and earlier

Users upgrading directly from 2.0 or earlier should also read the 2.1 Release Notes for caveats regarding the 2.0 -> 2.1 upgrade.

Contents

1. New Features
2. Improvements
3. Notable Bug-fixes
4. Important note for MySQL users

New Features

Personal Spaces

Two of the most frequent questions we get from Confluence customers have been: "How do I give my users their own wiki?" and "How do I give my users their own blog?" It seems everybody needs a little Personal Space.

Personal spaces belong to particular users, and rather than being listed on the dashboard, are available from the user's profile. (Future versions of Confluence will feature a 'people browser' to make it easier to discover the interesting personal spaces on your server). They can contain pages and news items like any other space, be searched and browsed. They can be kept private, or opened up so the whole world can view and edit them, just like global spaces.
Your personal space is your own private workspace within Confluence. You can optionally let other people view or contribute to it.

**Who can contribute to your personal space?**
You can customize these permissions once the space is created.

<table>
<thead>
<tr>
<th>Choose who can view content:</th>
<th>Choose who can contribute (create and edit) content:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Me</td>
<td>Me</td>
</tr>
<tr>
<td>Registered users - anyone logged into Confluence</td>
<td>Registered users - anyone logged into Confluence</td>
</tr>
<tr>
<td>Anonymous - anyone, logged in or not</td>
<td>Anonymous - anyone, logged in or not</td>
</tr>
</tbody>
</table>

**Choose Theme**
To change the theme of this space, select one below.

- **Default Theme**
  Use the globally configured look and feel. You can customise colour schemes and layouts manually.

- **Left Navigation Theme**
  Provides a navigation bar on the left-hand side of the screen.

Confluence’s search and RSS builder interfaces have been updated to make it easy to choose whether you’re interested in personal spaces or not.

Oh, and if you create a personal space, don’t forget to upload (or choose) your own profile picture, so people can see who you are.
Localisation/Internationalisation

Confluence now supports drop-in language packs to change the language of the user interface. The global administrator can select a default language for the entire site, while individual users can set their preferred language in their preferences.

No language packs are currently available, but we are currently working with our global partners so we can begin to provide translations. If you are interested in translating Confluence into another language, you can find instructions on building a language pack here: Language Pack Plugins.

CAPTCHA Support

Many of the more public Confluence wikis have been suffering at the hands of spammers. CAPTCHA support adds the familiar ‘type in this word’ question to signup, edit and comment forms, to defeat automated spamming bots. You can turn on CAPTCHA from the global administrative console, and also choose which users will, or will not be subject to the spam check.
Plugin Improvements

Each version of Confluence is more customisable than the last. One of the most exciting things to come from our recent plugin competition was learning just how creative our plugin developers are, and discovering more ways we can help them add features to Confluence.

- Job Plugins and Trigger Plugins allow you to schedule periodic tasks to run within Confluence.
- Web UI Plugins allow plugin developers to add new links, buttons and tabs to the Confluence interface, and make it easier for theme developers to stay up to date with changes to the Confluence UI.
- Code Formatting Plugins allow you to plug support for new languages into the {code} macro (or override the existing language support with something better).

We've also made a number of improvements to the plugin system, including:

- Making sure that a single 'rogue' plugin can't bring down the whole plugin subsystem.
- Enabling 'conditional get' for plugin resources, so browsers don't download them again and again.
- Fixing problems that may occur when a servlet or component plugin is reloaded or upgraded. (With many thanks to Dan Hardiker of Adaptavist.)

New atlassian-user Configuration Syntax

As promised, we have cleaned up the configuration file syntax for our atlassian-user user management library. This should make it much easier to configure Confluence to use external user repositories such as LDAP. You can find details of the new configuration file format here: Add LDAP Integration

Improvements

Permissions Changes

In Confluence 2.1 and earlier, permissions that were assigned to Anonymous users were not automatically assigned to logged-in users, leading to the confusing situation where you could view a page when not logged in, but not view it when you were logged in.

In Confluence 2.2 and later, permissions that are assigned to the Anonymous user are also assigned to all logged in users. The sole exception to this rule is the global Use Confluence permission, which must still be explicitly granted to any user who wishes to log in. (This exception is necessary due to licensing restrictions).

Search

With help from Kelvin Tan, we've overhauled much of the underlying infrastructure of Confluence's search engine. Search in Confluence should now be more efficient, and some searches that were problematic before (such as wildcard* searches) now work as you would expect them to.

LDAP Performance

Confluence's performance against external LDAP user repositories should now be significantly faster.

Other

- The General Configuration screen is much better organised
- You can choose a space's initial permissions and theme when you create it
- Themes may now be packaged with icons that will be displayed in the theme selector (see the screenshot of the "create personal space" screen above for an example)
- Confluence Standalone is now packaged with Tomcat 5.5
- Atom feeds are now generated to the Atom 1.0 standard
- The back-end storage of attachment files has been changed to resolve a number of problems that were caused when the underlying filesystem did not support the character-set of the attachment filename
Important note for MySQL users

For users using MySQL with Confluence 2.2 (or higher), please ensure that you are using the latest (3.1.12) MySQL Java Connector. Earlier versions of the MySQL connector have a bug which is triggered by improvements in Confluence 2.2. These earlier connector versions will result in an error being recorded in your logs on upgrade (and will result in unstable operation of Confluence).

You can download the latest MySQL connector from the MySQL Java Connector 3.1 download page. Please be sure that you remove any older versions of the connector from your application server.

**Release Notes 2.2.1**

Confluence 2.2.1 is a maintenance release that resolves some issues users may have encountered using Confluence 2.2, including issues related to LDAP user management, i18n, personal spaces and drafts.

2.2.1 is a free upgrade for all customers who purchased their Confluence license after May 18th, 2004.

**Who should upgrade?**

Confluence is a recommended upgrade for all customers using Confluence with external LDAP user management. All other customers should consult the list of issues resolved, and determine if this release is necessary for their own deployments.

**Upgrade Procedure**

Upgrading Confluence should be pretty easy. If you are upgrading from Confluence 2.2, you can find instructions here. **We strongly recommend that you backup your confluence.home directory and database before upgrading!**
Draft Table Upgrade
Upgrading Confluence to 2.2.1 will cause all autosaved 'drafts' to be deleted from the database. Be sure everyone has saved their work before upgrading!

Confluence 2.2.1 and 2.2.1a
The current version available for download is 2.2.1a. 2.2.1 was originally released with an old version of the atlassian-plugins library, which caused the plugin fixes listed below not to be included in the release. Confluence 2.2.1a resolves that problem.

PageChildrenMacro IndexOutOfBoundsException error
Customers who downloaded 2.2.1 or 2.2.1a before the official announcement may encounter an error when using the (children) macro to view the children of other pages in the same space. There is a patch for this issue attached to CONF-6197

If you are upgrading from Confluence 2.1.5 or earlier, please check the release-notes of the other major Confluence releases:
- Release Notes 2.2
- Release Notes 2.1
- Release Notes 2.0
- Release Notes 1.4
- Release Notes 1.3
- Release Notes 1.2
- Release Notes 1.1

Changes in 2.2.1
For a complete list, see: Issues resolved for 2.2.1

External User Management
- Creating a new user will no longer cause a primary key violation on some Confluence installations. CONF-6092
- Fixed a regression where authentication against an external LDAP server via the old OSUser integration layer did not function. CONF-6092
- Fixed a possible ClassCastException on viewing a user's profile. CONF-6021

Plugins
Note: Due to a scheduling error, these fixes were not included in Confluence 2.2.1, but are in the supplementary 2.2.1a release.
- Component plugins are now correctly unregistered when they are removed. CONF-4041
- Plugins may now contain and reference dependent jar files. Thanks to Dan Hardiker of Adaptavist for the patch. PLUG-8
- Installing an older version of an already-installed plugin no longer causes an error. PLUG-12
- Removing an uploaded plugin no longer causes it to be deactivated the next time it is installed. PLUG-13

General Stability
- Confluence can now store drafts for spaces with long (>20 character) keys. CONF-6010
- Attachments stored in MySQL databases will no longer be silently truncated to 64KB. CONF-6120
- Global language setting is now saved correctly. CONF-6027
- Missing attachment data no longer causes PDF export to crash. CONF-6063
- Misleading "attachment missing" errors are no longer logged after a space import. CONF-6026

Improvements
- A Javascript alert warns users if they have left the CAPTCHA field blank. CONF-5984
- A link to the logged-in user's personal space is included on every page (from their full name). CONF-6056
- The (children) macro can now show the children of pages in another space. CONF-5986

Issues resolved for 2.2.1

Release Notes 2.2.2

Confluence 2.2.2 is a maintenance release that resolves some issues users may have encountered using Confluence 2.2, including issues related to PDF generation, internationalisation, backup/restore and more.

2.2.2 is a free upgrade for all customers who purchased their Confluence license after May 31st, 2005.

Who should upgrade?

Confluence 2.2.2 resolves CONF-6237, a bug related to the backup and restore of personal spaces. As such it is a recommended upgrade for customers wishing to restore or import data containing personal spaces. Other users should consult the list of resolved issues, and determine if the upgrade is necessary for their installation.

Upgrade Procedure

Upgrading Confluence should be pretty easy. If you are upgrading from Confluence 2.2 or 2.2.1, you can find instructions here. We strongly recommend that you backup your confluence home directory and database before upgrading!

If you are upgrading from Confluence 2.1.5 or earlier, please check the release-notes of the other major Confluence releases:

- Release Notes 2.2
- Release Notes 2.1
Changes in 2.2.2

Over 25 issues were resolved between Confluence 2.2.1 and 2.2.2. For a complete list, see: Issues resolved for 2.2.2

Backup/Restore

- An issue was resolved that could cause personal spaces to be imported incorrectly from backups. Existing backup files are still valid, the error was only during the re-importing process – CONF-6237

PDF Export

- PDF exports can now be generated for pages containing non-latin characters. To enable these exports you will need to provide Confluence with the correct font – CONF-1457
- PDF exports created in Confluence are now properly searchable, both in Confluence (CONF-1380) and in Adobe Acrobat (CONF-4529)

Other

- (UI) Fixed a Javascript error when saving a page with CAPTCHA disabled – CONF-6221
- (User management) Resolved an error when deleting a non-empty group – CONF-6082
- (i18n) Resolved issues with hard-coded English text in various places – CONF-6202
- (i18n) Resolved issues with internationalisation keys showing up in the permissions guide – CONF-6053

Issues resolved for 2.2.2

### Release Notes 2.2.3

Confluence 2.2.3 is a maintenance release that resolves some issues users may have encountered using Confluence 2.2, including issues related to LDAP user management, installation, backup/restore and more. This release also includes a patch for a serious security issue regarding global permissions.

2.2.3 is a free upgrade for all customers who purchased their Confluence license after June 8th, 2005.

**Who should upgrade?**

Confluence 2.2.3 resolves a security bug related to unauthorised modification of global permissions. As such this release is a recommended upgrade for all customers.

For users of older versions of Confluence who do not wish to upgrade, a patch for this issue will be available shortly.

**Upgrade Procedure**

Upgrading Confluence should be pretty easy. If you are upgrading from Confluence 2.2, 2.2.1 or 2.2.2, you can find instructions here. We strongly recommend that you backup your `confluence.home` directory and database before upgrading!

If you are upgrading from Confluence 2.1.5 or earlier, please check the release-notes of the other major Confluence releases:

- Release Notes 2.2
- Release Notes 2.1
- Release Notes 2.0
- Release Notes 1.4
- Release Notes 1.3
- Release Notes 1.2
- Release Notes 1.1

**Changes in 2.2.3**

As part of a new process for pushing out bug fix releases more quickly, this release follows just a week after the release of 2.2.2. Six issues were resolved between Confluence 2.2.2 and 2.2.3. For a complete list, see: Issues resolved for 2.2.3

**Global Permissions**

- A security problem was identified where unauthorised users could modify global permissions. For more information, including details on how to patch previous Confluence versions, please see the security advisory

**Backup/Restore**

- An issue was resolved where attachments were not imported from space exports. Existing backup files are still valid, the error was only during the re-importing process – CONF-6286

**External user management**

- Queries to LDAP repositories are now correctly escaped, so user and group names may contain commas – USER-106

**Other**

- (UI) Fixed parent link in preview of new page – CONF-6275
- (authentication) Fixed incorrect redirect from login when base URL contained an extra slash – CONF-6261
- (installation) Improved error handling during Confluence setup – CONF-6276

**Issues resolved for 2.2.3**
Errors were reported by the JIRA trusted connection.

- APP_UNKNOWN; Unknown Application: {0}; ["confluence:4557196"]

### Release Notes 2.2.4

Confluence 2.2.4 is a maintenance release that resolves an assortment of issues users may have encountered using Confluence 2.2.

2.2.4 is a free upgrade for all customers who purchased their Confluence license after June 22nd, 2005.

**Who should upgrade?**

Confluence 2.2.4 is a minor bugfix release. Customers should consult the list of issues resolved in this release to determine if it is worth their while upgrading.

Customers still running Confluence 2.2.2 or earlier are recommended to upgrade, as a significant security vulnerability was resolved in Confluence 2.2.3

**Upgrade Procedure**

Upgrading Confluence should be pretty easy. If you are upgrading from Confluence 2.2 - 2.2.3, you can find instructions here. We strongly recommend that you backup your confluence.home directory and database before upgrading!

If you are upgrading from Confluence 2.1.5 or earlier, please check the release-notes of the other major Confluence releases:

- Release Notes 2.2
- Release Notes 2.1
- Release Notes 2.0
- Release Notes 1.4
- Release Notes 1.3
- Release Notes 1.2
- Release Notes 1.1

**Changes in 2.2.4**

We are currently trialling a process of more frequent bugfix releases, to make fixes available as soon as possible to those people who want them. 2.2.4 resolves six issues:

See also: Issues Resolved for 2.2.4

**User Interface**

- The "Space Admin" tab is no longer displayed to non-administrators. (Even though the tab was visible, non-administrators could still not access any of the administrative functions) CONF-6385
- Personal spaces are no longer listed in the space picker in the feed builder CONF-6830
- Attempts to create news items with invalid characters now fail with the correct error message CONF-6358
**Performance**

- The velocity manager is no longer loaded twice, saving memory. CONF-6355
- The velocity cache now expires templates that have not been recently used, potentially saving memory. CONF-6339

**Developer API**

- Putting pages into, and removing them from the trash now trigger the correct events within Confluence CONF-6353

**Issues Resolved for 2.2.4**

Errors were reported by the JIRA trusted connection.

### Release Notes 2.2.6a

Confluence 2.2.6a is a maintenance release that resolves an assortment of issues users may have encountered using Confluence 2.2.

2.2.6a is a free upgrade for all customers who purchased their Confluence license after June 22nd, 2005.

**Who should upgrade?**

Confluence 2.2.6a is a minor bugfix release. Customers should consult the list of issues resolved in this release to determine if it is worth their while upgrading. Customers running Confluence 2.2.5 should upgrade, as 2.2.6a fixes a security problem which could allow an unauthorised user to modify space mail box configuration. Only version 2.2.5 is affected by this vulnerability. Customers running 2.2.5 who don't wish to upgrade can follow these instructions to patch the vulnerability.

Customers still running Confluence 2.2.2 or earlier are recommended to upgrade, as a significant security vulnerability was resolved in Confluence 2.2.3

**Upgrade Procedure**

Upgrading Confluence should be pretty easy. If you are upgrading from Confluence 2.2 - 2.2.3, you can find instructions here. We strongly recommend that you backup your confluence.home directory and database before upgrading!

If you are upgrading from Confluence 2.1.5 or earlier, please check the release-notes of the other major Confluence releases:

Changes in 2.2.6a

We are currently trialling a process of more frequent bugfix releases, to make fixes available as soon as possible to those people who want them. 2.2.6a resolves 20 issues.

A few of the issues are noted below, see Issues Resolved for 2.2.6a for a complete list.

User Interface

- The rich text editor allows underlining to be removed, and lists in tables are better behaved. CONF-6450, CONF-6508
- Users with capital letters in their names can watch pages and spaces. CONF-6489

LDAP

- LDAP users can be removed from local Confluence groups. CONF-6131
- The 'Change Password' link is no longer shown when LDAP is enabled. CONF-6360

Performance

- Indexing performance has been improved. CONF-6465

2.2.5 Security Patch

This patch fixes a minor security vulnerability regarding the administration of space mail accounts. It affects only Confluence 2.2.5.

To install this patch please download the three files attached to this page, stop Confluence and copy them to your WEB-INF/classes/com/atlassian/confluence/mail/actions directory, where they will replace the existing files. Then start Confluence.

**Release Notes 2.2.7**

Confluence 2.2.7 is a maintenance release that resolves an assortment of issues users may have encountered using Confluence 2.2. 2.2.7 is a free upgrade for all customers who purchased their Confluence license after July 28th, 2005.

**Who should upgrade?**

Confluence 2.2.7 is a minor bugfix release. Customers should consult the list of issues resolved in this release to determine if it is worth their while upgrading.

Customers still running Confluence 2.2.2 or earlier are recommended to upgrade, as a significant security vulnerability was resolved in Confluence 2.2.3

**Upgrade Procedure**

Upgrading Confluence should be pretty easy. If you are upgrading from Confluence 2.2 - 2.2.3, you can find instructions here. We strongly recommend that you backup your confluence home directory and database before upgrading!

If you are upgrading from Confluence 2.1.5 or earlier, please check the release-notes of the other major Confluence releases:

- Release Notes 2.2
- Release Notes 2.1
- Release Notes 2.0
- Release Notes 1.4
- Release Notes 1.3
- Release Notes 1.2
- Release Notes 1.1

**Changes in 2.2.7**
We are currently trialling a process of more frequent bugfix releases, to make fixes available as soon as possible to those people who want them. 2.2.7 resolves 23 issues.

A few of the issues are noted below, see Issues Resolved for 2.2.7 for a complete list.

**Task List Macro**
- Tasks with the same name in different lists are now distinguished. CONF-5809

**User Management**
- The manage groups page can now display an unlimited number of groups. CONF-6458
- Users that belong to more than 100 groups are now always able to login. CONF-6292

**PDF Export**
- Exporting pages to PDF which include other pages will now have correct links and not lose images. CONF-1155

**Internationalisation**
- Tree view of page hierarchy will not be truncated when using multi-byte character sets. CONF-5872

**Issues Resolved for 2.2.7**

Release Notes 2.2.8

Confluence 2.2.8 is a maintenance release that resolves an assortment of issues users may have encountered using Confluence 2.2.

Confluence 2.2.8 has slower indexing than previous versions. There is a fix for that regression here: CONF-6908

2.2.8 is a free upgrade for all customers who purchased their Confluence license after August 8th, 2005.

Who should upgrade?

Confluence 2.2.8 is a minor bugfix release. Customers should consult the list of issues resolved in this release to determine if it is worth their while upgrading.

Customers still running Confluence 2.2.2 or earlier are recommended to upgrade, as a significant security vulnerability was resolved in Confluence 2.2.3

Upgrade Procedure

Upgrading Confluence should be pretty easy. If you are upgrading from Confluence 2.2 - 2.2.3, you can find instructions here. We strongly recommend that you backup your confluence.home directory and database before upgrading!

If you are upgrading from Confluence 2.1.5 or earlier, please check the release-notes of the other major Confluence releases:

- Release Notes 2.2
- Release Notes 2.1
- Release Notes 2.0
- Release Notes 1.4

- Release Notes 1.1

Changes in 2.2.8

We are currently trialling a process of more frequent bugfix releases, to make fixes available as soon as possible to those people who want them. 2.2.8 resolves 22 issues.

A few of the issues are noted below, see Issues Resolved for 2.2.8 for a complete list.

- Exporting a space as HTML now creates an index page which includes all the pages in the export. CONF-6670
- Timeouts can be set for HTTP requests made from Confluence to RSS feeds and JIRA instances. CONF-8697
- RSS Autodiscovery works in Safari. CONF-4607
- When a group is deleted, space permissions for the group are now correctly removed. CONF-6733
- Change default background colour from grey to white. CONF-6733
- Non-breaking spaces are handled correctly when indexing. CONF-6685
- Rich text editor respects leading spaces in noformat macro. CONF-6527

**Release Notes 2.2.9**
Confluence 2.2.9 is a maintenance release that resolves an assortment of issues users may have encountered using Confluence 2.2. 2.2.9 resolves an indexing performance regression introduced in 2.2.8, and includes fixes for external user management, and MaxDB and Sybase compatibility.

2.2.8 is a free upgrade for all customers who purchased their Confluence license after September 9th, 2005.

Who should upgrade?

Confluence 2.2.9 is a minor bugfix release. Customers should consult the list of issues resolved in this release to determine if it is worth their while upgrading.

If you are running Confluence 2.2.8, but do not wish to upgrade to 2.2.9, we strongly recommend installing the patch attached to CONF-6908 instead to resolve an issue related to re-indexing performance.

Customers still running Confluence 2.2.2 or earlier are recommended to upgrade, as a significant security vulnerability was resolved in Confluence 2.2.3

Upgrade Procedure

Upgrading Confluence should be pretty easy. If you are upgrading from Confluence 2.2 - 2.2.3, you can find instructions here. We strongly recommend that you backup your confluence.home directory and database before upgrading!

If you are upgrading from Confluence 2.1.5 or earlier, please check the release-notes of the other major Confluence releases:

- Release Notes 2.2
- Release Notes 2.1
- Release Notes 2.0
- Release Notes 1.4
- Release Notes 1.3
- Release Notes 1.2
- Release Notes 1.1

Changes in 2.2.9

2.2.8 resolves approximately 25 issues. See Issues Resolved for 2.2.9 for a complete list. A few of the issues are noted below.

External user management:

- LDAP users are no longer given the option to change their passwords in Confluence – CONF-6144
- External users belonging to more than 100 groups can log in successfully – CONF-6292
- External users can be removed from local groups – CONF-6832

Database Compatibility

- 'Review restricted pages' report now succeeds on MaxDB – CONF-6849
- Fixed Sybase error when removing a space – CONF-6715

Indexing

- A re-indexing performance regression introduced in 2.2.8 has been resolved – CONF-6908
- Advanced search queries for specific index fields now work as expected – CONF-6714
- Errors in text extractors no longer cause index queue flushing to fail – CONF-6857

**Release Notes 2.2.10**

Confluence 2.2.10 is a maintenance release that resolves an assortment of issues users may have encountered using Confluence 2.2. 2.2.10 resolves an assortment of issues that were reported by customers.

2.2.10 is a free upgrade for all customers who purchased their Confluence license after November 30th, 2005.

**Who should upgrade?**

Confluence 2.2.10 is a minor bugfix release. Customers should consult the list of issues resolved in this release to determine if it is worth their while upgrading.

If you are running Confluence 2.2.8, but do not wish to upgrade to 2.2.10, we strongly recommend installing the patch attached to CONF-6908 to resolve an issue related to re-indexing performance.

Customers still running Confluence 2.2.2 or earlier are recommended to upgrade, as a significant security vulnerability was resolved in Confluence 2.2.3

**Upgrade Procedure**
Upgrading Confluence should be pretty easy. If you are upgrading from another Confluence 2.2.x version, you can find instructions here. We strongly recommend that you backup your `confluence.home` directory and database before upgrading!

If you are upgrading from Confluence 2.1.5 or earlier, please check the release-notes of the other major Confluence releases:

- Release Notes 2.2
- Release Notes 2.1
- Release Notes 2.0
- Release Notes 1.4
- Release Notes 1.3
- Release Notes 1.2
- Release Notes 1.1

**Changes in 2.2.10**

2.2.10 resolves over 40 issues. All these issues are listed below:

Release Notes 2.3

After much hard toil from the Confluence developers we are happy, nay ecstatic, to announce the availability of Confluence 2.3 (known affectionately as Snowy). Snowy is the eighth major update to Confluence. It supports clustered deployment as 'Confluence Massive', and introduces a people directory, activity statistics plugin, personal timezone preferences, and the ability to access Confluence via the Metaweblog and WebDAV APIs.

Confluence 2.3 is a free upgrade for any customer who purchased Confluence after January 4th, 2006.

Upgrading from Confluence 2.2.x

Upgrading Confluence should be fairly straightforward: you can find instructions here. We strongly recommend that you backup your confluence.home directory and database before upgrading!

Upgrading from Confluence 2.1 and earlier

Users upgrading directly from 2.1 or earlier should also read the 2.2 Release Notes for caveats regarding the 2.1 -> 2.2 upgrade.

Installation Notes

Known Issues and Patches
Please read the Known Issues and Patches section of the release-notes before installing Confluence 2.3. These issues were resolved with a new maintenance release of Confluence 2.3.1

Contents

1. New Features
2. Improvements

See also: Issues Resolved for 2.3

New Features

Confluence Massive

Confluence is now a clusterable application. This means that it is possible to run multiple Confluence servers behind a load-balancer, to provide high availability, and to scale Confluence beyond the capacity of a single server.

Confluence Massive uses Tangosol Coherence to share data between nodes (and many other things besides).

If you are thinking of running Confluence in a cluster, and need to know what is required and how it works, you can read Technical Overview of Clustering in Confluence.

You can find instructions for installing a Confluence cluster here: Confluence Cluster Installation.

Cluster Licensing

Confluence Massive clustering is only enabled if you have a clustered licence. For information on purchasing clustered Confluence licences, please check our pricing page, or contact our friendly sales team.

The People Directory

In version 2.2 (Shoalhaven), we added personal spaces to Confluence. Because of the potential for the proliferation of personal spaces we kept them off the Dashboard and search results by default, but this made it quite hard to find people in a Confluence site.
The People Directory, which you can find linked from the bottom of the Dashboard, gives you a way to browse through the other people who use a Confluence instance, their profiles and personal spaces.

If you find people whose personal spaces you want to follow, you can mark them as favourites from the people directory. This will add their personal spaces to your 'My' tab on the Dashboard, and will also make sure they're included when you search or make RSS feeds from your favourite spaces.

**Activity Tracking**

The activity plugin lets you know what's happening in Confluence: how many pages are being visited or edited in each space or across the whole site, which spaces or pages are the busiest, who are the most prolific editors.
You can view activity statistics for a space in Browse Space, or globally from the administration console.

The plugin also provides macros that allow you to embed usage data into a Confluence page: {usage}, {popular} and {topusers}.

Activity tracking does not work in a cluster, and will be disabled for clustered deployments. We're working on making the activity tracker clusterable in a future release. You can follow this issue in JIRA: CONF-7520

**Blogger and MetaWeblog API Support**

Confluence 2.3 bundles the Blogging RPC Plugin. This allows users to manage their News in Confluence using one of the many available blogger-compatible desktop clients.
You can read more about this plugin, including instructions for setting up various blogging clients for use with Confluence, on the plugin information page.

**WebDAV Client Support**

The Confluence WebDAV plugin allows users to mount Confluence as a shared drive, using the WebDAV protocol.

This provides a familiar interface for anyone who uses Confluence as a repository for files: you can browse your wiki straight from Windows Explorer or the Mac Finder; view Word or PDF versions of pages; upload attachments and edit attachments in place; create, edit and move pages.
For more information on the WebDAV plugin, check out: WebDAV Plugin

WebDAV is supported natively in Windows XP (as "Web Folders") and Mac OS X, although there are third-party clients that may provide different functionality or compatibility. We have a compatibility matrix if you're interested.

**Experimental**

WebDAV client support is currently experimental, and is disabled by default. You can turn it on from the Plugin management page in the global administration console.

**Improvements**

**Plugins**

- Adaptivist's fantastic Plugin Repository Client is bundled with Confluence.
- User Macro Plugins allow you to share user macros more easily.
- Lifecycle Plugins allow you to hook into Confluence startup and shutdown.
- Events are now produced when themes are applied, or colour-schemes modified.
- Confluence now ships with 'bundled' plugins that are installed when Confluence is installed, but are not hard-coded into the application (so they can be upgraded without upgrading Confluence).
- Plugin resources now set Last-Modified and ETag headers properly, so they can be conditionally retrieved by browsers.
- Confluence is now built entirely using Maven 2. More on this soon.

**Other Changes**

- Users can now choose to have dates and times displayed in their own timezone instead of the server's - CONF-1026.
- Most Confluence configuration data has been moved from the filesystem into the database.
- The Clickr Theme is bundled with Confluence.
- HTML exports are more reliable for sites with non-ASCII page titles - CONF-4862.
- You can now get users from multiple LDAP repositories at the same time (or different search paths in the same LDAP repository) - CONF-6034.
- Shortcut links can now have the substitution string in the middle of the URL (CONF-3246), and have custom display text and titles (CONF-514).
- User macros are more flexible: you can configure how macro bodies are pre-rendered (CONF-2293), and you can also specify that a user macro generates wiki markup instead of HTML (CONF-3780).
- Pages with large numbers of attached images no longer eat up too many database connections - CONF-6393.
- When creating an RSS feed with the feed builder, you can choose whether to see full content, diffs, or both - CONF-6321.
- Searches now default to AND rather than OR for combining search terms - CONF-5874.
- The login page no longer prompts you to log in when you're already logged in. - CONF-6843.
- Support for the Nintendo Wii.
- Various improvements to performance that should result in a faster display of pages, and fewer problems for servers with large numbers of space permissions.
- Many static resources in Confluence are cached more effectively, so browsers have to retrieve CSS and Javascript files significantly
Confluence 2.3 was originally accidentally shipped with three testing-only language packs. Since Sunday January 14th, the language packs have been removed from the distribution, but if you downloaded Confluence before that date they will be present. These language packs are machine translations, and are not intended for use on production systems (unless you're a native German speaker and really want a good laugh). If you downloaded an affected copy of Confluence and want to remove these packs, delete de_DE-1.0.jar, ja_JP-1.0.jar and ru_RU-1.0.jar from confluence/WEB-INF/lib.

- You need to apply this patch to enable LDAP user integration: CONF-7585
- If you have problems restoring backups please apply the patch included in this issue: CONF-7584
- Due to class name changes, if you're upgrading from an existing system running:
  2. DB2 - you need to edit confluence.home/confluence.cfg.xml and replace bucket.dialect.DB2Dialect with com.atlassian.hibernate.dialect.DB2Dialect. More information in this issue: CONF-7690
- Log file atlassian-confluence.log is not presently generated. Please see these instructions for enabling it.

And one was there, a stripling on a small and weedy beast,
  He was something like a racehorse undersized,
With a touch of Timor pony — three parts thoroughbred at least —
  And such as are by mountain horsemen prized.
He was hard and tough and wiry — just the sort that won't say die —
  There was courage in his quick impatient tread;
And he bore the badge of gameness in his bright and fiery eye,
  And the proud and lofty carriage of his head.

- The Man from Snowy River, A. B. 'Banjo' Paterson

FileAppender log4j.properties

The 2.3 log4j.properties file doesn't specify a file for the FileAppender (because the necessary lines haven't been uncommented). Hence the log files normally generated via the file appender, logs/atlassian-confluence.log, is presently missing?

If you experience this situation and see errors in the logs such as:

```
log4j:WARN File option not set for appender [confluencelog].
log4j:WARN Are you using FileAppender instead of ConsoleAppender?
log4j:ERROR No output stream or file set for the appender named [confluencelog].
```

- Please uncomment the following lines in the log4j.properties file located under confluence/WEB-INF/classes and restart Confluence
  (ie remove the #'s)

Release Notes 2.3.1

Confluence 2.3.1 is a maintenance release that resolves an assortment of issues users may have encountered using Confluence 2.3.

2.3.1 is a free upgrade for all customers who purchased their Confluence license after January 23rd, 2006.

Who should upgrade?

Confluence 2.3.1 is a bugfix release which resolves some significant issues in Confluence 2.3. Customers running Confluence 2.3 should review the list of resolved issues below, and upgrade if this release fixes any problems with their current Confluence installation.

Customers running releases older than 2.3 and wishing to upgrade should use this version also.

Significant issues for customers upgrading to Confluence 2.3
**LDAP integration:** Confluence 2.3 shipped with a broken user migration script for customers wishing to integrate LDAP servers with their Confluence installation. 2.3.1 ships with a fixed version of this script which can also be obtained from CONF-7585.

**Upgrading with MySQL:** Customers using Confluence with MySQL may have had difficulty upgrading their instances to Confluence 2.3. This issue has been resolved in 2.3.1.

**Significant issues for existing Confluence 2.3 users**

- **Backup import:** Confluence 2.3 users wishing to import backups into their Confluence instance should upgrade to 2.3.1 or apply the patch listed against CONF-7584.

**Upgrade Procedure**

Upgrading Confluence should be pretty easy. If you are upgrading from another Confluence 2.2.x or Confluence 2.3 version, you can find instructions here. We strongly recommend that you **backup your `confluence.home` directory and database before upgrading!**

**Upgrading from Confluence 2.1 and earlier**

Users upgrading directly from 2.1 or earlier should also read the [2.2 Release Notes](#) for caveats regarding the 2.1 -> 2.2 upgrade.

**Changes in 2.3.1**

2.3.1 resolves 20 issues. All these issues are listed below:

Errors were reported by the JIRA trusted connection.

*Errors were reported by the JIRA trusted connection.*

Release Notes 2.3.2

Confluence 2.3.2 is a maintenance release that resolves an assortment of issues users may have encountered using Confluence 2.3.1

Warning for LDAP users
Confluence 2.3.2 has a serious bug that prevents it from working with LDAP servers. Please use Confluence 2.3.3 instead.

2.3.2 is a free upgrade for all customers who purchased their Confluence license after February 12th, 2006.

Who should upgrade?
Confluence 2.3.2 is a bugfix release which resolves some significant issues in Confluence 2.3.1 Customers running Confluence 2.3.1 and 2.3 should review the list of resolved issues below, and upgrade if this release fixes any problems with their current Confluence installation.

Customers running releases older than 2.3 and wishing to upgrade should use this version also.

Upgrade Procedure
Upgrading Confluence should be pretty easy. If you are upgrading from another Confluence 2.2.x or Confluence 2.3 version, you can find instructions here. We strongly recommend that you backup your confluence.home directory and database before upgrading!

Upgrading from Confluence 2.1 and earlier
Users upgrading directly from 2.1 or earlier should also read the 2.2 Release Notes for caveats regarding the 2.1 -> 2.2 upgrade.

Changes in 2.3.2

2.3.2 resolves 22 issues. All these issues are listed below:

Release Notes 2.4

The Atlassian Confluence team is proud to present to you Confluence 2.4! What happened to 2.4 and 2.4.1? Let's just say we gave them a good workout.

Confluence 2.4 is the ninth release of Confluence. It introduces much awaited support for editable comments, the ability to mail a page to groups of users and includes the usual slew of fixes since the last stable release.
Confluence 2.4 is the first in a series of frequent, small releases planned for the first half or 2007, that will help us get the functionality you want from Confluence, faster. For more information on our new release schedule, you might want to read this blog post.

Confluence 2.4.2 is a free upgrade for any customer who purchased Confluence after March 13th, 2006.

Upgrading from Confluence 2.2.x and 2.3.x

Upgrading Confluence should be fairly straightforward: you can find instructions here. We strongly recommend that you backup your confluence.home directory and database before upgrading!

Upgrading from Confluence 2.1 and earlier

Users upgrading directly from 2.1 or earlier should also read the 2.2 Release Notes for caveats regarding the 2.1 -> 2.2 upgrade.

Contents

1. New Features
2. Improvements

See also: Issues Resolved for 2.4.2

New Features

Editable Comments

Say so long! to those annoying typos and ill-structured sentences as comments in Confluence are now editable. Comments may be edited by the original author or the administrator for the space in which the comment was posted.

Confluence has a ten minute grace period after the comment is posted in which updates will not be flagged in the user interface. This is in acknowledgment of the fact that most edits within this period are for correcting minor typos and formatting which will not impact the flow of conversation.

For more information, see the Confluence user guide: Editing a Comment

Page Mailing

Confluence 2.4 ships with the Mail Page plugin allowing users to conveniently send the contents of a Confluence page to other interested parties. You can easily specify who you want the page mailed to by using a combination of:

- Email addresses
- Confluence user names
- Confluence group names

For security reasons, the Mail Page plugin is disabled by default. If you want to use this feature, an administrator will have to enable it. There must also be a mail server configured in the Confluence instance for this operation to be available.
This operation is reached via a page's Info tab.

For more information, see the Confluence user guide: E-mailing a Page

**Improvements**

- The People Directory no longer shows inactive users (CONF-7771)
- Log messages now have more context such as the URL of the page being displayed and the name of the logged in user (CONF-7878)

**Changes to the Page Permission API in Confluence 2.4**

Confluence 2.4 contains changes to the Confluence API that will affect any plugins that modify Page Permissions (aka ContentPermissions). Some methods have been deprecated, some new methods have been created, and one method now behaves differently from before.

Confluence 2.4 does not support having multiple view and edit permissions on a page. The Content Permission API allows such a state, but it should be avoided. For example, if a Page has multiple permissions set on it, these permissions will not be displayed properly via the user interface, and the pages may not be returned appropriately in a search.
Summary of Changes

<table>
<thead>
<tr>
<th>Deprecated methods</th>
</tr>
</thead>
<tbody>
<tr>
<td>ContentPermissionManager.getInheritedViewContentPermissions(Page)</td>
</tr>
<tr>
<td>ContentPermissionManager.getInheritedContentPermissions(ContentEntityObject contentEntityObject)</td>
</tr>
<tr>
<td>ContentEntityObject.getPermissions()</td>
</tr>
<tr>
<td>ContentEntityObject.getContentPermission(String permissionType)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Changed methods</th>
</tr>
</thead>
<tbody>
<tr>
<td>ContentPermissionManager.addContentPermission(ContentPermission permission, ContentEntityObject content)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Added methods</th>
</tr>
</thead>
<tbody>
<tr>
<td>ContentPermissionManager.setContentPermissions(List contentPermissions, ContentEntityObject content, String type)</td>
</tr>
<tr>
<td>ContentPermissionManager.getInheritedContentPermissionSets(ContentEntityObject contentEntityObject)</td>
</tr>
<tr>
<td>ContentEntityObject.getContentPermissionSet(String type)</td>
</tr>
<tr>
<td>ContentEntityObject.hasPermissions(String type)</td>
</tr>
<tr>
<td>ContentEntityObject.removeContentPermissionSet(ContentPermissionSet set)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Removed methods</th>
</tr>
</thead>
<tbody>
<tr>
<td>ContentPermissionManager.saveContentPermission(ContentPermission permission)</td>
</tr>
<tr>
<td>ContentPermissionManager.getContentUserPermission(ContentEntityObject contentEntityObject)</td>
</tr>
<tr>
<td>ContentEntityManager.onContentContextChanged(ContentEntityObject contentEntityObject)</td>
</tr>
<tr>
<td>ContentEntityObject.setPermissions(List permissions)</td>
</tr>
<tr>
<td>ContentEntityObject.clearPermissions(ContentPermissionManager permissionManager)</td>
</tr>
</tbody>
</table>

The change most likely to cause problems is:

ContentPermissionManager.addContentPermission(ContentPermission permission, ContentEntityObject content)

This method now adds a ContentPermission to the ContentEntityObject as one would expect. Previously if a ContentPermission already existed on the ContentEntityObject, then any existing ContentPermission would be removed. That is, the method really behaved as one would expect “setContentPermission” to behave. As a result, any code that used addContentPermission in Confluence 2.3 or earlier, should now use setContentPermissions with a single entry list.

Example conversion of old addContentPermission usage

```java
replace
    ContentPermissionManager.addContentPermission(p, c)
with
    ContentPermissionManager.setContentPermissions(java.util.Collections.singletonList(p), c, p.getType())
```

Most methods that used to return a ContentPermission have been replaced with methods that return a ContentPermissionSet. In some places we have used deprecation to point to the new method and reimplemented the old method to extract the first ContentPermission from the ContentPermissionSet.

As usual, the methods on the ContentPermissionManager should be used rather than those on the ContentEntityObject. The only ContentEntityObject method that should be used is getContentPermissionSet. Even that method should be used only to display the existing Permissions. All writes to the ContentPermissionSets should be performed via the ContentPermissionManager.

The onContentContextChanged method of the ContentPermissionManager was previously used to notify a ContentPermissionManager that cached permissions on a ContentEntityObject may be invalid. This is now accomplished by publishing a ContentPermissionEvent. That event is published automatically when changing ContentPermissions via the ContentPermissionManager.

No changes have been made yet to the the XML RPC API. It does not currently allow modification of ContentPermissions.

Release Notes 2.4.1

The Atlassian Confluence team is proud to present to you Confluence 2.4.2! What happened to 2.4 and 2.4.1? Let's just say we gave them a good workout.

Confluence 2.4 is the ninth release of Confluence. It introduces much awaited support for editable comments, the ability to mail a page to groups of users and includes the usual slew of fixes since the last stable release.

Release Notes 2.4.3

Confluence 2.4.3 is a maintenance release that resolves an assortment of issues users may have encountered using Confluence 2.4.2. 2.4.3 is a free upgrade for all customers who purchased their Confluence license after March 22nd 2006.

Who should upgrade?

Confluence 2.4.3 is a recommended upgrade release which resolves some significant issues in Confluence 2.4.2. Customers running older versions of Confluence should review the list of resolved issues below, and upgrade if this release fixes any problems with their current Confluence installation.

Customers running releases older than 2.4 and wishing to upgrade should use this version also.

Upgrade Procedure

Upgrading Confluence should be pretty easy. If you are upgrading from another Confluence 2.2.x or Confluence 2.3 version, you can find instructions here.

*We strongly recommend that you backup your confluence.home directory and database before upgrading!*

Upgrading from Confluence 2.1 and earlier

Users upgrading directly from 2.1 or earlier should also read the 2.2 Release Notes for caveats regarding the 2.1 -> 2.2 upgrade.

Changes in 2.4.3

2.4.3 resolves 15 issues. All these issues are listed below:

Errors were reported by the JIRA trusted connection.

Release Notes 2.4.4

Confluence 2.4.4 is a recommended upgrade release that resolves issues users may have encountered using Confluence 2.4.3 or earlier. 2.4.4 is a free upgrade for all customers who purchased their Confluence license after March 30th 2006.

Who should upgrade?

Confluence 2.4.4 is a recommended upgrade release that resolves issues users may have encountered using Confluence 2.4.3 or earlier. Customers running older versions of Confluence should review the list of resolved issues below, and upgrade if this release fixes any problems with their current Confluence installation.

Customers running releases older than 2.4 and wishing to upgrade should upgrade directly to 2.4.4.

Upgrade Procedure

Upgrading Confluence should be pretty easy. If you are upgrading from another Confluence 2.2.x or Confluence 2.3 version, you can find instructions here. We strongly recommend that you backup your confluence.home directory and database before upgrading!

Upgrading from Confluence 2.1 and earlier

Users upgrading directly from 2.1 or earlier should also read the 2.2 Release Notes for caveats regarding the 2.1 -> 2.2 upgrade.

Source Release

Please note that the source release for 2.4.4 is currently unavailable. We have scheduled a fix for this which should be included in 2.4.5. Please see CONF-8007 for more details.

Changes in 2.4.4

2.4.4 resolves 17 issues. All these issues are listed below:

Release Notes 2.4.5

Confluence 2.4.5 is a maintenance release that resolves issues users may have encountered using Confluence 2.4.4 or earlier.

2.4.5 is a free upgrade for all customers who purchased their Confluence license after April 12th 2006.

Who should upgrade?

Confluence 2.4.5 is a recommended upgrade release which resolves some significant issues in Confluence 2.4.4. Customers running older versions of Confluence should review the list of resolved issues below, and upgrade if this release fixes any problems with their current Confluence installation.

Customers running releases older than 2.4 and wishing to upgrade should upgrade directly to 2.4.5.

Upgrade Procedure

Upgrading Confluence should be pretty easy. If you are upgrading from another Confluence 2.2.x or Confluence 2.3 version, you can find instructions here.

*We strongly recommend that you backup your confluence home directory and database before upgrading!*

Upgrading from Confluence 2.1 and earlier
Users upgrading directly from 2.1 or earlier should also read the 2.2 Release Notes for caveats regarding the 2.1 -> 2.2 upgrade.

### Release Notes 2.5

The Atlassian Confluence team is proud to present Confluence 2.5. Confluence 2.5 is the tenth release of Confluence. It introduces more flexible page restrictions, and also includes a number of minor fixes.

Confluence 2.5 is a free upgrade for any customer who purchased Confluence after April 27th, 2006.

#### Upgrading from Confluence 2.2 and later

Upgrading Confluence should be fairly straightforward: you can find instructions here. We strongly recommend that you backup your confluence.home directory and database before upgrading!

#### Upgrading from Confluence 2.1 and earlier

Users upgrading directly from 2.1 or earlier should also read the 2.2 Release Notes for caveats regarding the 2.1 -> 2.2 upgrade.

#### Introducing flexible page restrictions

Page restrictions give you the ability to choose who may read and/or edit any given page.
By popular request, page restrictions have been enhanced and can now be assigned to multiple people and/or groups:

![Restrictions](image)

Other significant issues resolved

**Dynamic task list JRE incompatibilities**

Many customers have been prevented from upgrading the Java runtime hosting their Confluence instance due to CONF-4082, an issue which would prevent existing dynamic task lists from working with the new JRE. This issue has been resolved in Confluence 2.5 allowing dynamic task list users to upgrade and downgrade between Java versions without experiencing conversion exceptions.

**contentbylabel macro supports AND condition**

You may now use the operator=AND parameter with the contentbylabel macro to select pages that have all of the supplied labels. (CONF-4969)

Release Notes 2.5.1

Confluence 2.5.1 is a maintenance release that resolves issues users may have encountered using Confluence 2.5 or earlier.

2.5.1 is a free upgrade for all customers who purchased their Confluence license after May 7th 2006.

Who should upgrade?

Confluence 2.5.1 is a bugfix release which resolves some significant issues in Confluence 2.5. Customers running older versions of Confluence should review the list of resolved issues below, and upgrade if this release fixes any problems with their current Confluence installation.

Customers running releases older than 2.5 and wishing to upgrade should upgrade directly to 2.5.1.

Upgrade Procedure

Upgrading Confluence should be pretty easy. If you are upgrading from another Confluence 2.2.x or a later version, you can find instructions here.

*We strongly recommend that you backup your *confluence.home* directory and database before upgrading!*

Upgrading from Confluence 2.1 and earlier

Users upgrading directly from 2.1 or earlier should also read the 2.2 Release Notes for caveats regarding the 2.1 -> 2.2 upgrade.

Changes in 2.5.1

2.5.1 resolves these issues:

| CONF-6057 | Users can manually restrict pages operations to custom groups of which they are not members | Resolved | Fixed |
| CONF-5783 | Markup with emoticon should have whitespace around it | Resolved | Fixed |
| CONF-5682 | User level permission on pages | Resolved | Fixed |
| CONF-5677 | Javascript exception NS_ERROR_NOT_AVAILABLE when changing editor tabs in Firefox | Resolved | Fixed |
| CONF-5334 | Hovering over the tabs in the editor view causes page to scroll on IE | Resolved | Fixed |
| CONF-5159 | Draft saving incorrectly encodes characters in Safari | Resolved | Fixed |
| CONF-5134 | Blogpost macro - order by created date only | Resolved | Fixed |
| CONF-5080 | Administrators cannot restrict View/Edit of a page to a group that the administrator does not belong | Resolved | Fixed |
| CONF-4986 | Pages with permissions are not being listed under 'Restricted Pages' in the space admin screens. | Resolved | Fixed |
| CONF-4969 | contentbylabel macro should support AND condition | Resolved | Fixed |
| CONF-4082 | ConversionException on dynamic tasklist after JDK version change | Resolved | Fixed |
| CONF-4005 | Page permission info is misleading | Resolved | Fixed |
| CONF-3908 | Can not set page permissions via Remote API | Resolved | Fixed |
| CONF-3759 | The login.action page should forward to the homepage when logged in. | Resolved | Fixed |
| CONF-3701 | Allow selection of multiple users and multiple groups (or both) for page level permissions | Resolved | Fixed |
Errors were reported by the JIRA trusted connection.

**Release Notes 2.5.2**

Confluence 2.5.2 is a maintenance release that resolves issues users may have encountered using Confluence 2.5 or earlier.

2.5.2 is a free upgrade for all customers who purchased their Confluence license after May 22nd 2006.

**Who should upgrade?**

Confluence 2.5.2 is a bugfix release which resolves some significant issues in Confluence 2.5. Customers running older versions of Confluence should review the list of resolved issues below, and upgrade if this release fixes any problems with their current Confluence installation.

Customers running releases older than 2.5 and wishing to upgrade should upgrade directly to 2.5.2.

**Upgrade Procedure**

Upgrading Confluence should be pretty easy. If you are upgrading from another Confluence 2.2.x or a later version, you can find instructions here.

*We strongly recommend that you backup your `confluence.home` directory and database before upgrading!*

**Upgrading from Confluence 2.1 and earlier**

Users upgrading directly from 2.1 or earlier should also read the [2.2 Release Notes](#) for caveats regarding the 2.1 -> 2.2 upgrade.

**Changes in 2.5.2**

2.5.2 resolves these issues:

Errors were reported by the JIRA trusted connection.

Release Notes 2.5.3

Confluence 2.5.3 is a maintenance release that resolves issues users may have encountered using Confluence 2.5 or earlier.

2.5.3 is a free upgrade for all customers who purchased their Confluence license after May 30th 2006.

Who should upgrade?

Confluence 2.5.3 is a bugfix release which resolves some significant issues in Confluence 2.5. Customers running older versions of Confluence should review the list of resolved issues below, and upgrade if this release fixes any problems with their current Confluence installation.

In particular, 2.5.3 fixes a problem which could cause indexing to fail when extracting text from unprintable encrypted PDF files.

Customers running releases older than 2.5 and wishing to upgrade should upgrade directly to 2.5.3.

Shared Mode Removed

This release removes the 'Shared Mode' setting from General Configuration. If you have shared mode enabled you should disable it before upgrading.

Upgrade Procedure

Upgrading Confluence should be pretty easy. If you are upgrading from another Confluence 2.2.x or a later version, you can find instructions here.

We strongly recommend that you backup your confluence.home directory and database before upgrading!

Upgrading from Confluence 2.1 and earlier

Users upgrading directly from 2.1 or earlier should also read the 2.2 Release Notes for caveats regarding the 2.1 -> 2.2 upgrade.

Changes in 2.5.3

2.5.3 resolves these issues:

Release Notes 2.5.4

Confluence 2.5.4 is a maintenance release that resolves issues users may have encountered using Confluence 2.5 or earlier.

2.5.4 is a free upgrade for all customers who purchased their Confluence license after June 13th 2006.

Who should upgrade?

Confluence 2.5.4 is a bugfix release which resolves some significant issues in Confluence 2.5. Customers running older versions of Confluence should review the list of resolved issues below, and upgrade if this release fixes any problems with their current Confluence installation.

Customers running releases older than 2.5 and wishing to upgrade should upgrade directly to 2.5.4.

Upgrade Procedure

Upgrading Confluence should be pretty easy. If you are upgrading from another Confluence 2.2.x or a later version, you can find instructions here.

We strongly recommend that you backup your confluence.home directory and database before upgrading!

Upgrading from Confluence 2.1 and earlier

Users upgrading directly from 2.1 or earlier should also read the 2.2 Release Notes for caveats regarding the 2.1 -> 2.2 upgrade.

**Release Notes 2.5.5**

Confluence 2.5.5 is a recommended upgrade that resolves issues you may have encountered in Confluence 2.5.4 or earlier. Confluence 2.5.5 resolves two security bugs, related to space permissions and invalid characters in space names and keys.

As such this release is a recommended upgrade for all customers.

Confluence 2.5.5 is a free upgrade for all customers who purchased their Confluence license or maintenance renewal after July 26th 2006.

**Upgrading to Confluence 2.5.5**

Upgrading Confluence should be fairly straightforward. You can find instructions here. We strongly recommend that you backup your confluence.home directory and database before upgrading!

**Changes in 2.5.5**

Patch for security issues

Confluence 2.5.5 resolves two security bugs, related to:

- space permissions
- invalid characters in space names and keys.

For more information, please see the security advisory.

**Server ID**

Starting with release 2.5.5, Confluence will generate a server ID for you. Server ID has replaced License ID on the License Details page. You will find the server ID useful when contacting Atlassian support.

Server ID:

- is generated when you install Confluence for the first time
- exists for the life of the Confluence instance
- survives an upgrade
- is held in the database
- is not bound to a specific licence
- is the same for all servers in a cluster.

**Translations for rich text editor now compatible with Confluence language pack plugins**

Thank you to everyone who voted for this popular fix.

The rich text editor in Confluence shows text in tooltips, warnings and other messages. If you are using Confluence in a language other than English, you will want to translate these messages as well as the standard Confluence text.

With Confluence 2.5.5:

- The translations for the rich text editor can be part of a Confluence language pack plugin.
- If your language pack does not contain translations for the rich text editor, the text will show in English. (Before 2.5.5, it showed the 'key' value rather than English.)
- Partial translations of rich text editor messages are already included in the professional French and German language packs. Full translation is under construction.

This makes things much simpler!

You will find more information here:

- Overview of language pack translations
- Technical overview of language pack plugins
- Specific information on translating the rich text editor

**Other fixes in 2.5.5**

2.5.5 resolves these issues:

Upgrade Guide 2.5.5

Who should upgrade?

Confluence 2.5.5 is a recommended upgrade that resolves issues you may have encountered in Confluence 2.5.4 or earlier. Confluence 2.5.5 resolves two security bugs, related to space permissions and invalid characters in space names and keys.

As such this release is a recommended upgrade for all customers.

Confluence 2.5.5 is a free upgrade for all customers who purchased their Confluence license or maintenance renewal after July 26th 2006.

If you are running a release older than 2.5 and you want to upgrade, you should upgrade directly to 2.5.5. Refer to the upgrade procedure below.

Upgrade Procedure

Upgrading Confluence should be pretty easy. We strongly recommend that you backup your confluence.home directory and database before upgrading!

If you are upgrading from Confluence 2.2.x or a later version, you can find instructions here.

If you are upgrading directly from 2.1 or earlier, you should also read the 2.2 Release Notes for warnings about the 2.1 -> 2.2 upgrade.

Release Notes 2.5.6

Confluence 2.5.6 is a recommended upgrade that resolves a number of security bugs and other issues you may have encountered in Confluence 2.5.5 or earlier.

As such this release is a recommended upgrade for all customers.

Confluence 2.5.6 can be downloaded from http://www.atlassian.com/software/confluence/ConfluenceDownloadCenter.jspa, and is a free upgrade for all customers who purchased their Confluence license or maintenance renewal after August 8th 2006.

Upgrading to Confluence 2.5.6

Upgrading Confluence should be fairly straightforward. You can find instructions here. We strongly recommend that you backup your confluence.home directory and database before upgrading!

Changes in 2.5.6

- For details about the security fixes, please see the security advisory.
- CONF-8944 resolves a Crowd integration issue for Confluence 2.5.6 and later.
- The Crowd integration fix will be ported to previous Confluence versions in the near future - please see CONF-9122.

Here's a complete list of the bug fixes in Confluence 2.5.6:

Errors were reported by the JIRA trusted connection.

### Upgrade Guide 2.5.6

**Who should upgrade?**

Confluence 2.5.6 is a recommended upgrade that resolves a number of security bugs and other issues you may have encountered in Confluence 2.5.5 or earlier.

As such this release is a recommended upgrade for all customers.

Confluence 2.5.6 can be downloaded from [http://www.atlassian.com/software/confluence/ConfluenceDownloadCenter.jspa](http://www.atlassian.com/software/confluence/ConfluenceDownloadCenter.jspa), and is a free upgrade for all customers who purchased their Confluence license or maintenance renewal after August 8th 2006.

If you are running a release older than 2.5 and you want to upgrade, you should upgrade directly to 2.5.6. Refer to the upgrade procedure below.

### Upgrade Procedure

Upgrading Confluence should be fairly straightforward. *We strongly recommend that you backup your confluence.home directory and database before upgrading!*

If you are upgrading from Confluence 2.2.x or a later version, please see the [Confluence Upgrade Instructions](http://www.atlassian.com/software/confluence/ConfluenceDownloadCenter.jspa).

If you are upgrading directly from 2.1 or earlier, you should also read the [2.2 Release Notes](http://www.atlassian.com/software/confluence/ConfluenceDownloadCenter.jspa) for warnings about the 2.1 -> 2.2 upgrade.

### Release Notes 2.5.7

Confluence 2.5.7 is a recommended upgrade that resolves two issues you may have encountered in Confluence 2.5.6:

- Indexing errors claiming 'too many open files', caused by duplicate libraries in the Confluence web application.
- Caching should be enabled by default for the LDAP configuration in `atlassian-user.xml`.

Confluence 2.5.7 can be downloaded from [http://www.atlassian.com/software/confluence/ConfluenceDownloadCenter.jspa](http://www.atlassian.com/software/confluence/ConfluenceDownloadCenter.jspa), and is a free upgrade for all customers who purchased their Confluence license or maintenance renewal after 30 August 2006.

If you don’t wish to upgrade to 2.5.7, but do want a fix for issue **CONF-9251** ("Too many open files" error during index operations), you can manually remove the duplicate libraries shipped in the Confluence web application. Please follow the instructions on the JIRA issue.

### Upgrading to Confluence 2.5.7

Upgrading Confluence should be fairly straightforward. You can find instructions here. *We strongly recommend that you backup your confluence.home directory and database before upgrading!*

Upgrade Guide 2.5.7

Who should upgrade?

Confluence 2.5.7 is a recommended upgrade that resolves two issues you may have encountered in Confluence 2.5.6:

- Indexing errors claiming 'too many open files', caused by duplicate libraries in the Confluence web application.
- Caching should be enabled by default for the LDAP configuration in atlassian-user.xml.

Confluence 2.5.7 can be downloaded from [http://www.atlassian.com/software/confluence/ConfluenceDownloadCenter.jspa](http://www.atlassian.com/software/confluence/ConfluenceDownloadCenter.jspa), and is a free upgrade for all customers who purchased their Confluence license or maintenance renewal after 30 August 2006.

If you are running a release older than 2.5 and you want to upgrade, you should upgrade directly to 2.5.7. Refer to the upgrade procedure below.

Upgrade Procedure

Upgrading Confluence should be fairly straightforward. *We strongly recommend that you backup your confluence.home directory and database before upgrading!*

If you are upgrading from Confluence 2.2.x or a later version, please use the [Confluence Upgrade Instructions](http://www.atlassian.com/software/confluence/ConfluenceDownloadCenter.jspa).

If you are upgrading directly from 2.1 or earlier, you should also read the [2.2 Release Notes](http://www.atlassian.com/software/confluence/ConfluenceDownloadCenter.jspa) for warnings about the 2.1 -> 2.2 upgrade.

Release Notes 2.5.8

Confluence 2.5.8 is a **highly recommended** upgrade that resolves some issues in the user management framework and a memory leak in Confluence 2.5.x.

You can download Confluence 2.5.8 from [http://www.atlassian.com/software/confluence/ConfluenceDownloadCenter.jspa](http://www.atlassian.com/software/confluence/ConfluenceDownloadCenter.jspa). This upgrade is free for all customers with active Confluence software maintenance as at 3 October 2007.

This release has been made available after the Confluence 2.6 release date. This 2.5.8 version is for customers who want to fix the issues listed below, but do not want all the new functionality and theme changes in Confluence 2.6 yet.

Upgrading to Confluence 2.5.8

Upgrading Confluence should be fairly straightforward. You can find instructions [here](http://www.atlassian.com/software/confluence/ConfluenceDownloadCenter.jspa). *We strongly recommend that you backup your confluence.home directory and database before upgrading!*

Changes in 2.5.8

Here's a complete list of the bug fixes in Confluence 2.5.8:

Errors were reported by the JIRA trusted connection.

Upgrade Guide 2.5.8

Who should upgrade?

Confluence 2.5.8 is a highly recommended upgrade that resolves some issues in the user management framework and a memory leak in Confluence 2.5.x.

You can download Confluence 2.5.8 from http://www.atlassian.com/software/confluence/ConfluenceDownloadCenter.jspa. This upgrade is free for all customers with active Confluence software maintenance as at 3 October 2007.

If you are running a release older than 2.5 and you want to upgrade, you should upgrade directly to 2.5.8, referring to the upgrade procedure below.

Upgrade procedure

Upgrading Confluence should be fairly straightforward. We strongly recommend that you back up your confluence.home directory and database before upgrading!

If you are upgrading from Confluence 2.2.x or a later version, please use the Confluence Upgrade Instructions.

If you are upgrading directly from 2.1 or earlier, you should also read the 2.2 Release Notes for warnings about the 2.1 -> 2.2 upgrade.

Release Notes_1.0.1

Confluence 1.0.1

Over the course of the last month of supporting Confluence 1.0, there are a number of patches that we have been distributing to fix specific problems our users have encountered. Confluence 1.0.1 is a maintenance release into which all these patches have been integrated.

Who Should Upgrade?

All the issues that were resolved for this release are listed below. We have not snuck in any other changes: what you see here in the release notes is precisely what you will get. If you find something on the list that directly affects you, or that you feel justifies the effort of an upgrade, then do so. Otherwise, feel free to stick with 1.0.

Upgrade Procedure

If You Have Customised osuser.xml

If you have customised Confluence’s user-management, for example to integrate it with LDAP or JIRA, you will have to integrate your changes to account for the caching OSUser providers we introduced in Confluence 1.0.1. See this document for more details: [Confluence Caching OSUser Provider]. Updated instructions for integrating with JIRA user management are here: Delegate user management to use JIRA logins

Otherwise

To avoid the possibility of data-loss, you should back up your ConfluenceHome directory and your database before upgrading, and perform a full backup from within the application.

Changes in 1.0.1

See also Issues Resolved for 1.0.1

Direct Attachment Links

In response to a loud demand from users, links to attachments using the [*attachment.jpg] syntax will download the attachment file directly, instead of linking to an anchor in the destination page.

Sybase ASE Support

Confluence 1.0.1 resolves the following problems that were causing Confluence not to work with Sybase ASE 12.5.1:
ORDER-BY mappings failing on Sybase (CONF-1021)
Can't add users under Sybase (CONF-1022)
Weird datatype error under Sybase (CONF-1024)
Sybase doesn't like complicated distinct selects (404 page fails) (CONF-1025)
Backup import fails under Sybase (CONF-1063)

These bug-fixes may also improve Confluence's compatibility with other untested databases. They will not, however, have any effect on Confluence's operation against PostgreSQL, MySQL or HSQL.

Microsoft SQL Server Dialect in Setup Page

The Microsoft SQL Server database dialect was missing from the database setup page. It has now been added to the list. Confluence has not yet been tested on Microsoft SQL Server, and the usefulness of this option is not yet guaranteed. However, since the Sybase issues above are now resolved and SQL Server belongs to the same family as Sybase, it would be well worth a try.

JIRA User Provider Caching

Users who were linking their user management to JIRA's using the supplied provider were experiencing significant performance problems as a result. 1.0.1 introduces caching to the user provider, which should speed up these installations significantly.

Global Reports Visibility

Under Confluence 1.0, the global "undefined pages" and "orphaned pages" reports did not properly filter out pages that the user could not see. The user could not see the content of any page they did not have access to, but they could learn of the existence of (and names of) pages and spaces they were not permitted to see. This bug is fixed in 1.0.1

Locale-Independent Dates in Backup/Restore

In Confluence 1.0, dates were written into backup files using a localised representation of the month. As such, if you exported Confluence data from a server in one locale it might not import successfully into a server with a different Locale setting. Confluence 1.0.1 still recognises the 1.0 export format, but its own exports will write out dates in a locale-independent format.

As noted above, this means that data exported from Confluence 1.0.1 can not be imported successfully into Confluence 1.0.

Fix Browser Crash on Viewing Some Templates

Previously, if you created a template containing no variables, then anyone attempting to preview or use that template would have their browser hang in an infinite Javascript loop. Confluence 1.0.1 fixes this bug.

Typo Fixed on User Group Editing Page

A single-character change from "privilage" to "privilege".

Strangely unviewable Release Notes 2.6

The Atlassian Confluence team is delighted to present Confluence 2.6. We kept you waiting a bit longer than usual for this one, but now it's here and it's packed full of goodies and looks cleaner and fresher than ever before. Read on, to find that piece of functionality you've been longing for.

Confluence 2.6 is the eleventh major release of Confluence. This release is a free upgrade for any customers who purchased their Confluence license or maintenance renewal after August 22nd 2006.

• Many thanks for your issues and votes. They help us keep improving our products.
• Here's a full list of issues resolved in 2.6.

Upgrading to Confluence 2.6

Upgrading Confluence should be fairly straightforward. Please follow the instructions here. We strongly recommend that you back up your confluence.home directory and database before upgrading!

2.6 highlights

New look and feel

• Default font now Arial instead of Verdana.
• Fresh, clean look and feel - these release notes are an example of the new style.
• If you prefer the original Confluence look and feel, select the Confluence Classic Theme when creating a space.
2 Profile picture shows on comments

- In the new themes (Confluence Default and Clickr)

3 Personalised 'Recently Updated' section on Dashboard

- Changes are grouped by person.
- Includes profile picture and a summary of the change.

4 Space description on Dashboard

- List of spaces on the Dashboard now includes a short description of the space.
Labels included in templates

- Include labels when adding a page template.
- New pages based on the template will automatically include the labels.
- Read the documentation.

Default content for home pages

- Confluence site administrators can define default content for a space.
- Home page for newly-added spaces will include the default content.
- Read the documentation.
Social Bookmarking plugin now bundled with Confluence

- Use Confluence to share bookmarks with your team.
- Plugin will be enabled by default.
- You can create a bookmark for any space in which you have 'create page' permission.
- To view your bookmarks, go to the ‘Bookmarks’ tab under ‘Browse Space’.
- To add a bookmark, click the ‘Add Bookmark’ option.
- Drag the bookmarklet from the ‘Bookmarks’ tab onto your browser toolbar to create bookmarks anytime.
- Use the {bookmarks} macro to display a list of bookmarks anywhere in Confluence.
- Subscribe to an RSS feed for your bookmarks.
- Read the [documentation]
WebDAV plugin now bundled with Confluence

- The WebDAV 1.1 plugin is now bundled with Confluence.
- Plugin will be disabled by default.
- Use Confluence like a network drive:
  - Access Confluence content via a WebDAV client, such as 'My Network Places' in Microsoft Windows.
  - Read and write to spaces, pages and attachments in Confluence, provided that you have permission.
  - You will be asked to log in, and the standard Confluence permissions apply.
- To configure the WebDAV permissions and other settings, site administrators can choose the WebDAV Configuration option on the Administration Console.
- Read the documentation.

TaskList plugin now bundled with Confluence

- New and improved version of Dynamic Tasklist - you can:
  - Re-order tasks reliably.
  - Include some wiki markup (links, simple formatting) in the task names.
  - Edit task names.
  - Drag a task from one list to another.
  - Assign priorities to tasks.
  - Sort tasks.
  - Change task lists in edit mode - the task lists are now stored in the page.
- Every change saves a version of the page - no lost information.
- Easy upgrade: The new Dynamic Tasklist plugin will find any task lists in the previous format and automatically upgrade them to the new format.
- Read the documentation.

Back-dating and renaming news items

- Set the date of a news item to earlier than today, upon creation.
- Rename a news item at any time.

Official support of MySQL 5.0

- MySQL 5.0 is supported when used with Confluence 2.5 and above.

PDF export of image-generating macros

- Macro plugins which produce images now export to PDF, .doc and .html formats.

The Confluence 2.6 team

Development
Paul Curren
Upgrade Notes Overview

All upgrades between Confluence versions have a lot in common. Please refer to our general information about upgrading Confluence first.

Typically, each major release of Confluence comes with some specific recommendations for upgrading from the previous major version. If you plan to upgrade and skip a few Confluence versions, you must read the upgrade notes for all major versions between your current version and the latest version, to make sure you do not miss something important.

For example:
If you plan to upgrade from Confluence 2.8 to Confluence 3.0, read the upgrade notes for Confluence 2.9 and Confluence 2.10, as well as those for Confluence 3.0.

Also, we strongly recommend that you read the upgrade notes for any minor releases indicated in the list below, since they contain important information that will affect your Confluence upgrade.

Below are links to the upgrade notes for the latest major releases, including any important upgrade notes for minor releases:

- Confluence 3.0.1 Upgrade Notes
- Confluence 3.0 Upgrade Notes
- Confluence 2.10 Upgrade Notes
- Confluence 2.9 Upgrade Notes
- Confluence 2.8 Upgrade Notes
- Confluence 2.7 Upgrade Notes
- Confluence 2.6 Upgrade Notes

You will find the upgrade notes attached to the release notes for the relevant version.

Release Notes

**Confluence Setup Guide**

Before running the Confluence Setup Wizard described below, please follow the instructions on installing Confluence.

When you access Confluence in your web browser for the first time, you will see the Confluence Setup Wizard. This is a series of screens which will prompt you to supply some default values for your Confluence site. It will also offer some more advanced options for setting up data connections and restoring data from a previous installation.

On this page:

- 1. Start the Setup Wizard
- 2. Enter your License Key
- 3. Choose your Installation Type
- 4. Custom Installation: Database Configuration
- 5. Custom Installation: External Database
- 6. Custom Installation: Load Content
- 7. Custom Installation: Restore Data from Backup
- 8. Enter Details of your Confluence System Administrator
- 9. Setup is Complete
1. Start the Setup Wizard

1. If Confluence is not already running, i.e., if you did not configure it to start automatically during installation, you need to start it now:
   - If you are running Confluence Standalone on Windows, click ‘Start’..., ‘Programs’..., ‘Atlassian Confluence’..., ‘Start in Console’.
   - If you are running Confluence Standalone on a MAC, click ‘Applications’..., ‘Atlassian Confluence’.
   - Or run the start-up script found in the bin folder of your Installation directory:
     - startup.bat for Windows.
     - startup.sh for Unix-based systems.
   - Mac OS X users will be prompted to choose an application. Choose the Terminal application in the Utilities folder.

2. Go to the following web address in your web browser: http://localhost:8080
   - The above web address uses port ‘8080’. If you chose a different port during installation, change ‘8080’ to the number you chose.
   - You should see the Licensing screen described below.
   - If an error message appears, first check that you’re using the port which you specified during installation. Then check the Installation FAQ.

2. Enter your License Key

   ![Screenshot: Licensing and Installation Type]

   **Confluence Setup Wizard**

   Confluence needs some information before it is fully installed. If at any stage of the installation you need more information, check out the online setup guide. If you get stuck, you can email us, or ask a question in the Confluence forum.

   **Enter License**
   
   Please enter your Confluence license key below - either commercial or evaluation. You can generate an evaluation license instantly online.

   **Choose Installation Type**
   
   There are two ways to install Confluence. If you are in any doubt as to which you should choose, you should select the standard installation.

   **Standard Installation**
   
   Install Confluence with default settings and an embedded database. This is strongly recommended for anyone evaluating or demonstrating Confluence, as it will get you up and running as quickly as possible.

   **Custom Installation**
   
   Perform a custom setup. Select this option if you want to configure Confluence with an external database, or initialise the server with your own data.

   **Hint:** The above image and all the images on this page are screenshots. Clicking an image will not configure Confluence.

1. Find your Confluence license key:
   - If you don’t have your license key handy, you can retrieve your existing key.
   - If you do not already have a Confluence license, you can obtain one now:
     - Copy your ‘Server ID’ from the Setup Wizard's Licensing screen, shown on the screenshot above.
Confluence 3.0 Documentation

- Obtain a trial, free or commercial licence.
- Type or paste your license key into the ‘License Key’ field, shown on the screenshot above.

3. Choose your Installation Type

Refer to the screenshot above. In this step, you will choose whether you want a standard or a custom installation.

**Option 1: Standard Installation** — Set up Confluence with the embedded HSQLDB database and default settings. This option will also install a ‘Demonstration Space’ with some example content to get you working with Confluence as quickly and easily as possible. You may upgrade to another type of database later on.

**Hint: Who should choose this option?**
- Choose the standard installation if you are evaluating Confluence or if you are new to Confluence.
- This option is not recommended for production instances of Confluence.

**For production use, we strongly recommend that you connect to an external database rather than using the embedded database. The standard installation is therefore not suitable for production installations.**

Next, you will be asked for details of your system administrator. Go to step 8 below. Yes, you really can skip all the steps between.

**Option 2: Custom Installation** — Customise your Confluence instance to use your own database and your own data.

**Hint: What options does the custom installation offer?**
- Connect Confluence to an external database. *Recommended for production instances of Confluence.*
- Restore data from an existing Confluence database.
- Install Confluence without the demonstration content.

4. Custom Installation: Database Configuration

**Screenshot: Database Configuration**

**Choose a Database Configuration**

Choose where Confluence should store its data

**Embedded Database**

The embedded database will allow Confluence to operate without an external database.

We strongly recommend against using this on a production server. This is recommended for evaluating and demonstrating Confluence only. Production systems should consider an external database for improved scalability and reliability. A guide on how to migrate your data can be found [here](#).

**External Database**

If you wish to store your Confluence data in an external database, choose it from the list of supported databases. This is recommended for production systems.

If your database is not listed in the menu, you may configure an “Unsupported Database”, but be aware that Confluence may not be fully tested

The above screen appears if you have chosen a custom installation of Confluence. You can choose to use the embedded database supplied with your Confluence installation, or to connect to an external database.

**Option 1: Embedded Database** — If you select this option, Confluence will use an embedded HSQLDB database. You should only select this option if you are evaluating Confluence, or for demonstration purposes.

**✓** You can migrate to another database later on, if you wish.
The embedded database is not recommended for production use.

Option 2: External Database — If you wish Confluence to use an external database, select your database type from the database dropdown list and then click the 'External Database' button.

Read more information about supported databases.

For production deployments of Confluence, we recommend that you use an external database to ensure your data is kept safe and consistent.

5. Custom Installation: External Database

Before you Start

- Character encoding:
  - We strongly recommend that character encoding is consistent across your database, application server and web application, and that you use UTF-8 encoding.
  - Before setting up your database, please read about configuring character encoding.
- Database name: When creating a new external database, give it the name 'confluence'.

You can choose to configure your database via a standard JDBC connection or via a server-managed datasource connection. Choose one of the two options below.

Option 1: Standard Database Connection — This uses a standard JDBC database connection. Connection pooling is handled within Confluence.

Screenshot: Standard (JDBC) Connection

Setup Standard Database

Supply the following information:

- Driver Class Name — The Java class name for the appropriate database driver. This will depend on the JDBC driver, and will be found in the documentation for your database. You will also need to put the appropriate database driver 'jar' file in the server's classpath. For the standalone version, this means copying the jar file into the <confluence-install>/lib directory.
- Database URL — The JDBC URL for the database you will be connecting to. This will depend on the JDBC driver, and will be found in the documentation for your database.
- User Name — A valid username which Confluence will use to access your database.
- Password — The password corresponding to the above username.

You will also need to know:

- The size of the connection pool Confluence should maintain. If in doubt, just go with the default provided.
- What kind of database you're connecting to, so you can tell Confluence which dialect it needs to use.

Option 2: Datasource Connection — This asks the Java application server for a database connection. You will need to have configured a datasource into your application server.

Screenshot: Datasource Connection
Setup Datasource Connection

If "java:comp/env/jdbc/DatasourceName" doesn't work, try "jdbc/DatasourceName" (or vice versa)

Datasource Name: [java:comp/env/jdbc/]

Supply the following information:

- **Datasource Name** — The JNDI name of the datasource, as configured in the application server.
  Note: Some servers will have JNDI names like jdbc/datasourcename; others will be of the form java:comp/env/jdbc/datasourcename. Consult your application-server documentation.

You will also need to know:

- What kind of database you're connecting to, so you can tell Confluence which dialect it needs to use.

6. Custom Installation: Load Content

Select one of the following options:

- **Example Site** — This option will load Confluence's 'Demonstration Space'. Select this if you are using Confluence for the first time, or if you want the Demonstration Space for your other Confluence users. The Demonstration Space helps to familiarise you with Confluence and what it can do for you. You can then continue using your Confluence deployment as normal — there's no need to reinstall later.
- **Empty Site** — Select this option if you are already familiar with Confluence. You will need to create at least one space before you can start adding content to the site.
- **Restore from Backup** — Select this option if you want to use Confluence data from a previous installation.

7. Custom Installation: Restore Data from Backup

Select one of the following options:

- **Example Site** — This option will load Confluence's 'Demonstration Space'. Select this if you are using Confluence for the first time, or if you want the Demonstration Space for your other Confluence users. The Demonstration Space helps to familiarise you with Confluence and what it can do for you. You can then continue using your Confluence deployment as normal — there's no need to reinstall later.
- **Empty Site** — Select this option if you are already familiar with Confluence. You will need to create at least one space before you can start adding content to the site.
- **Restore from Backup** — Select this option if you want to use Confluence data from a previous installation.
This option allows you to reload your data from an existing Confluence installation into your new Confluence site during the initial setup procedure. You can choose to upload data from a zipped backup file, or to restore from a backup file on your file system.

**Option 1: Upload a zipped backup to Confluence** — This option will load the data from a zipped backup file.

To create a backup file from your existing version of Confluence, go to the 'Backup & Restore Administration Console' section of your Administration Console.

To restore from a zipped backup:

1. Browse for the relevant daily backup file or a file you have created via a manual backup.
2. Check 'Build Index' to build the data index, used for the search.
3. Click the 'Upload and Restore' button.

**Option 2: Restore a backup from the filesystem** — This option is recommended if you have a very large daily backup file (greater than 100MB), or a daily backup file that is already on the server and doesn’t require uploading.

1. Copy the backup file into the `restore` directory inside your confluence `Home directory` and then refresh the page. You should now see your backup file appear on the 'Restore Data' screen (pictured above), in the box beneath the heading 'Restore a backup from the filesystem'.
2. Check 'Build Index' to build the data index, used for the search.
3. Click the 'Restore' button.

When the restore process has finished, you are ready to log in to Confluence. The system administrator account and all other information has been transferred from your previous Confluence installation.

---

8. Enter Details of your Confluence System Administrator

_Screenshot: System Administrator_
1. Enter the following information to set up your system administrator's user account:
   - **Username** — The username under which the system administrator will log in to Confluence, e.g. 'jsmith'.
   - **Password** — The password which the system administrator will use to log in.
   - **Confirm** — Enter the same password again.
   - **Name** — The system administrator's full name, e.g. 'John Smith'.
   - **Email** — The system administrator's email address, e.g. 'jsmith@example.com'.
2. Click 'Next'.

9. Setup is Complete

Congratulations! You have installed and set up Confluence. Click the 'Start using Confluence now' link to open the 'Demonstration Space' in your Confluence wiki. This space contains some sample content and ideas, to help you get started quickly.

External Database

Custom Installation - Connecting to an External Database

This page is part of the Confluence Setup Guide.

Before you Start

- **Character encoding:**
  - We strongly recommend that character encoding is consistent across your database, application server and web application, and that you use UTF-8 encoding.
  - Before setting up your database, please read about configuring character encoding.
- **Database name:** When creating a new external database, give it the name 'confluence'.

You can choose to configure your database via a standard JDBC connection or via a server-managed datasource connection. Choose one of
the two options below.

**Option 1: Standard Database Connection** — This uses a standard JDBC database connection. Connection pooling is handled within Confluence.

**Screenshot: Standard (JDBC) Connection**

**Setup Standard Database**

Supply the following information:

- **Driver Class Name** — The Java class name for the appropriate database driver. This will depend on the JDBC driver, and will be found in the documentation for your database. You will also need to put the appropriate database driver 'jar' file in the server's classpath. For the standalone version, this means copying the jar file into the `<confluence-install>/lib` directory.
- **Database URL** — The JDBC URL for the database you will be connecting to. This will depend on the JDBC driver, and will be found in the documentation for your database.
- **User Name** — A valid username which Confluence will use to access your database.
- **Password** — The password corresponding to the above username.

You will also need to know:

- The size of the connection pool Confluence should maintain. If in doubt, just go with the default provided.
- What kind of database you're connecting to, so you can tell Confluence which dialect it needs to use.

**Option 2: Datasource Connection** — This asks the Java application server for a database connection. You will need to have configured a datasource into your application server.

**Screenshot: Datasource Connection**

**Setup Datasource Connection**

Supply the following information:

- **Datasource Name** — The JNDI name of the datasource, as configured in the application server. Note: Some servers will have JNDI names like `jdbc/datasourcename`; others will be of the form `java:comp/env/jdbc/datasourcename`. Consult your application-server documentation.

You will also need to know:

- What kind of database you're connecting to, so you can tell Confluence which dialect it needs to use.

**Restoring from Backup During Setup**

This page is part of the Confluence Setup Guide.

*Screenshot: Restoring Data*
**Restore Data**

There are two ways you can restore a backup:

- **Upload a zipped backup to Confluence**
  
  ![Upload a zipped backup to Confluence](image)
  
  To be able to search your data an index needs to be built. You can postpone this for later by unchecking the box below.
  
  - **Build Index**
  
  ![Build Index](image)
  
  OR

- **Restore a backup from the filesystem**:
  
  Recommended if you have a large backup file.
  
  Backups must be copied into the `C:\data\vid` directory inside your Confluence `Home directory` and then refresh the page. You should now see your backup file appear on the 'Restore Data' screen (pictured above), in the box beneath the heading 'Restore Data'.
  
  ![No files in directory](image)
  
  - **Build Index**
  
  ![Build Index](image)
  
  - **Restore**

This option allows you to reload your data from an existing Confluence installation into your new Confluence site during the initial setup procedure. You can choose to upload data from a zipped backup file, or to restore from a backup file on your file system.

**Option 1: Upload a zipped backup to Confluence** — This option will load the data from a zipped backup file.

To create a backup file from your existing version of Confluence, go to the 'Backup & Restore' section of your Administration Console.

To restore from a zipped backup:

1. Browse for the relevant daily backup file or a file you have created via a manual backup.
2. Check 'Build Index' to build the data index, used for the search.
3. Click the 'Upload and Restore' button.

**Option 2: Restore a backup from the filesystem** — This option is recommended if you have a very large daily backup file (greater than 100MB), or a daily backup file that is already on the server and doesn’t require uploading.

1. Copy the backup file into the `restore` directory inside your Confluence `Home directory` and then refresh the page. You should now see your backup file appear on the 'Restore Data' screen (pictured above), in the box beneath the heading 'Restore Data'.
2. Check 'Build Index' to build the data index, used for the search.
3. Click the 'Restore' button.

When the restore process has finished, you are ready to log in to Confluence. The system administrator account and all other information has been transferred from your previous Confluence installation.

**Database Configuration**

This document provides information on configuring an external database.
The Embedded Database for Evaluation Purposes

The Confluence installation includes an embedded HSQLDB database, supplied for the purpose of evaluating Confluence.

If you are using the embedded database, the database files are stored in the \database folder under your Confluence Home directory. See also Important Directories and Files.

- **Embedded Database is Not Suitable for Production Instances of Confluence**
  
  Production instances of Confluence should use an external database. When using the default HSQLDB database, you run the risk of unrecoverable data loss due to not being transaction safe.
  
  - Corruption is occasionally encountered after sudden power loss and can usually be corrected using this data recovery procedure.
  - HSQLDB is still suitable for evaluation purposes, but the risk can only be eliminated by switching databases.
  
  External databases may also provide superior speed and scalability.

Selecting an External Database

- **The XML backup built into Confluence is not well suited for database migration for large data sets (see Alternative Backup Strategy for reference). Choose your database wisely; if you need to migrate later, Atlassian support will refer you to a third party database migration tool. Vote for CONF-12599 to add a more robust strategy for large implementation migrations.**

Below is more information on selecting and migrating to an external database:

- Migrating to a Different Database
- List Of Supported Databases
- Known Issues For Supported Databases

Database Setup

Setup instructions are shown below. Click a database to review the setup guide and any known issues.

- MySQL
- PostgreSQL
- Oracle
- SQL Server
- DB2

Other databases should use these instructions.

Optimising Database Performance

To improve database responsiveness:

- Known Issues For Supported Databases

Database Troubleshooting

For solving database-related problems:

- Troubleshooting External Database Connections
- Troubleshooting the Embedded Database (HSQL DB)
- Interpreting DB2 error codes
- Known Issues For Supported Databases

Obtain technical support from Troubleshooting Problems & Requesting Technical Support.

Migrate to Another Database

This document outlines how to migrate your data from your existing database to another database. It is designed for migrating from an evaluation to a production database. Large data sets will require third party database migration tools.
You should use this method when moving from the embedded DB to an external DB, or from one type of external DB to another (e.g. Oracle to Postgres). If you are simply moving your DB from one server to another you can just change the JDBC URL in <confluence.home>/confluence.cfg.xml (if you are using a direct JDBC connection) or in the definition of your datasource (if you are connecting via a datasource).

There are two ways you can perform the migration:

1. Method one is the standard procedure.
2. For large installations of Confluence using version 2.2 or later: If the total size of attachments on your installation exceeds 500MB, use method two.

On this page:
- Method One - Standard Procedure
  - Step One: Backing up your data
  - Step Two: Configuring the Confluence Home Directory
  - Step Three: Setting up the new database
  - Step Four: Setting up Confluence with the new database
- Method Two - For large installations
  - Step One: Backing up your data
  - Step Two: Configuring the Confluence Home Directory
  - Step Three: Setting up new database
  - Step Four: Setting up Confluence with the new database
- A Note about Case Sensitivity in your Database
- Troubleshooting

Limitations of Database Migration

The XML backup built into Confluence is not well suited for database migration for large data sets (see Alternative Backup Strategy for reference). If the procedures below do not work, use a commercial database migration tool. Vote for CONF-12599 to add a more robust strategy for large implementation migrations.

Method One - Standard Procedure

Step One: Backing up your data

1. Create a backup of your existing data. This is done from the Administration Console. Instructions on how to create a backup can be found here.
2. Shut down and backup the Confluence Home Directory.
3. If you are already using an external database, please make a backup of it using the utilities that were installed with it.

Note which plugins are currently installed/enabled, so that you can reinstate them later.

Step Two: Configuring the Confluence Home Directory

1. Create a new Confluence Home Directory. You can place this directory anywhere you like and give it a name of your choice.
2. Open WEB-INF/classes/confluence-init.properties file in your Confluence installation and change the confluence.home property to point to this new Confluence Home Directory.

Step Three: Setting up the new database

Perform the database setup instructions for your database.

Step Four: Setting up Confluence with the new database

If your databases are not already configured for Confluence, refer to Database Configuration to setup your database access.

1. Make sure that the JDBC drivers for your database are available to the application server. If you don't already have the JDBC driver, please download one from here.
2. Make sure that your database is using a case-sensitive collation. Please refer to the section on case sensitivity below and see this issue for more details: CONF-7917.
3. If you are running the standalone version of Confluence, copy your JDBC database driver (a .jar file, into the <confluence-install>/lib folder.
4. Start up Confluence. You will see the Confluence Setup Wizard.
5. Select 'Custom Install'.
6. Select your database from the drop down list.
7. Select 'Direct JDBC' and then enter the details of the new database you want to migrate to.

Read the documentation on the Setup Wizard for more detailed explanation.
8. When prompted, restore the contents of the backup you made in Step One into the new Confluence site.

Your old Confluence data will now be imported to your new database.

**Method Two - For large installations**

**Step One: Backing up your data**

1. Before proceeding with these instructions please check that:
   - you are upgrading from at least Confluence version 2.2 and
   - your attachments are stored in the file system, and not in your database. (To migrate between attachment storage systems, please see [Attachment Storage Configuration](#)).
   - These instructions will not work if either of the above is not true.
2. From Confluence, go to Administration -> Backup & Restore and create a manual backup that excludes attachments.
3. Shut down and back up the Confluence Home Directory.
4. If you are already using an external database, please make a backup of it using the utilities that were installed with it.

**Step Two: Configuring the Confluence Home Directory**

1. Create a new Confluence Home Directory. You can place this directory anywhere you like and give it a name of your choice.
2. Open WEB-INF/classes/confluence-init.properties file in your Confluence installation and change the confluence.home property to point to this new Confluence Home Directory.

**Step Three: Moving your attachments**

Move the contents of your attachments directory from your old Confluence Home to your new Confluence Home.

**Step Four: Setting up new database**

Perform the database setup instructions for your database.

**Step Five: Setting up Confluence with the new database**

If your databases are not already configured for Confluence, refer to Database Configuration to setup your database access.

1. Make sure that the JDBC drivers for your database are available to the application server. If you don't already have the JDBC driver, please download one from [here](#).
2. Make sure that your database is using a case-sensitive collation. Please refer to the section on case sensitivity below and see this issue for more details: CONF-7917.
3. If you are running the standalone version of Confluence, copy your JDBC database driver (a .jar file), into the <confluence-install>/lib folder.
4. Start up Confluence. You will see the Confluence Setup Wizard.
5. Select ‘Custom Install’.
6. Select your database from the drop down list.
7. Select ‘Direct JDBC’ and then enter the details of the new database you want to migrate to.
   - Read the documentation on the Confluence Setup Wizard for more detailed explanation.
8. When prompted, restore the contents of the backup you made in Step One into the new Confluence site.

**A Note about Case Sensitivity in your Database**

*Collation* refers to a set of rules that determine how data is sorted and compared. Case sensitivity is one aspect of collation. Other aspects include sensitivity to kana (Japanese script) and to width (single- versus double-byte characters).

Case-sensitive or case-insensitive collation — how should you create your Confluence database? What about when you are migrating your existing Confluence instance from one database to another?

**Setting up a New Confluence Instance**

For new Confluence instances, we recommend using case-sensitive collation for your Confluence database, which is the default collation type used by many database systems. The Confluence application itself reduces all usernames into lower-case characters before they are stored in the Confluence database. Therefore, ‘joebloggs’, ‘joeBloggs’, ‘JoeBloggs’, etc. will be treated as the same username on a Confluence installation with case-sensitive database collation.

**Migrating an Existing Confluence Instance to a Different Database**

The default Confluence Standalone configuration uses case-sensitive database collation. This is often the case with databases on several other systems which were created under default conditions. Therefore, if you are migrating from this type of configuration to a new database, we recommend that the new database uses case-sensitive collation. If you use case-insensitive collation, you may encounter data integrity problems after migration (for example, via an XML import) if data stored within your original Confluence site required case-sensitive distinctions.

**Troubleshooting**

If you're unable to restore your XML backup, consult our Troubleshooting Guide.
The Embedded HSQLDB Database

The Confluence installation includes an embedded HSQLDB database, supplied for the purpose of evaluating Confluence.

If you are using the embedded database, the database files are stored in the \database folder under your Confluence Home directory. See also Important Directories and Files.

**Embedded Database is Not Suitable for Production Instances of Confluence**

Production instances of Confluence should use an external database. When using the default HSQLDB database, you run the risk of unrecoverable data loss due to not being transaction safe.

- Corruption is occasionally encountered after sudden power loss and can usually be corrected using this data recovery procedure.
- HSQLDB is still suitable for evaluation purposes, but the risk can only be eliminated by switching databases. External databases may also provide superior speed and scalability.

**List Of Supported Databases**

The Confluence installation includes a pre-configured HSQLDB database for evaluation purposes only. For safe production use, you need to configure Confluence to use an external database listed below.

**Supported Databases**

Confluence supports the following database systems, provided they are running on a Windows, Unix (NetBSD, FreeBSD, OpenBSD, Solaris, Linux), Mac OS X on X86 or X86-64 processors.

<table>
<thead>
<tr>
<th>Database</th>
<th>Supported in Confluence 3.0 (JUN/2009)</th>
<th>Works with Confluence 3.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>PostgreSQL</td>
<td>8.1, 8.2</td>
<td>8.0, 8.3</td>
</tr>
<tr>
<td>Oracle</td>
<td>10.1, 10.2</td>
<td>11</td>
</tr>
<tr>
<td>MySQL</td>
<td>5.0.28 and above</td>
<td>5.0 - 5.0.27</td>
</tr>
<tr>
<td>DB2</td>
<td>8.2, 9.7</td>
<td></td>
</tr>
<tr>
<td>SQL Server</td>
<td>2005</td>
<td></td>
</tr>
</tbody>
</table>

☆ Column labelled 'Works with' as opposed to 'Supported in': We assume that Confluence works fine with these database versions. But please be aware that we don't test these versions regularly and that we may ask you to upgrade to a supported platform before we can provide more detailed support.

If your database does not appear on this list, please read the questions and answers about supported platforms.

If you have no preference, we recommend using PostgreSQL — it is scalable, free, and easy to set up. For database setup information, see Database Configuration and Database Setup For Any External Database.

Refer to the list of known issues for these databases.

**Unsupported Databases**

For Confluence 2.10 and later, MySQL 4.1.x is not supported — please upgrade to MySQL 5.
The decision to deprecate this database was announced previously.

There is a workaround to enable MySQL 4.1.x.

- Database JDBC drivers

**Database Setup For Any External Database**

If you are using Confluence in a production environment, data should be stored in an external database. The embedded database is bundled for evaluation purposes and does not offer full transactional integrity in the event of sudden power loss.

This document provides instructions for setting up Confluence for use with a production-ready database. It covers both migration from an evaluation installation of Confluence and installation of an empty database during initial setup. The following specific database guides have additional information:
- PostgreSQL Guide
- MySQL Guide
- Oracle Guide
- SQL Server

**Preparation**

Install the following on the Confluence server:
- Database administration tool, for example DBVisualizer
- JDBC database drivers
- The database server (unless accessed remotely)

The instructions refer to two particular directories:
- The `<Confluence Installation Directory>` is the directory where you unpacked the Standalone Confluence download.
- The `<Confluence Home Directory>` is the directory where Confluence stores its data, which you set by editing the `confluence-init.properties` file in `confluence/WEB-INF/classes`.

**Database Setup**

Create the schema and setup permissions:

1. Visit the Database Configuration page to review any known issues and database setup for your database.
2. Create a new schema using the correct database encoding.
3. Create a user with full read/write access to the Confluence schema, including the ability to create tables.
4. If the database only permits users to log in from approved hosts (e.g. `localhost`), grant database access permission for the Confluence server.
5. If the database is hosted remotely to the Confluence server, set up any firewall permissions.
6. Test the connection by using the database administration tool installed on the Confluence server to log in to the database.

---

**Migration From an Evaluation Instance of Confluence**

Continue here if you are migrating from an evaluation instance with the built-in database. If you are installing Confluence for the first time, continue below.

**Create Backups**

To keep any existing Confluence content:

1. If you are already using an external database, use your database administration tool to create a full database backup.
2. Manually create an XML backup of Confluence under 'Administration' -> 'Backup & Restore'. If you have less than 100MB of attachments, check 'Backup attachments' when creating the backup. If you have over 100MB of attachments, you should not check the 'Backup attachments' and instead you should manually copy the `/attachments` directory in your Confluence home to a backup location. This attachments directory will later be copied into the new home directory.
3. Download the backup file to a backup location.

**Database Connection Setup**

Set up Confluence's database connection:

1. Stop Confluence if it is already running.
2. The JDBC database drivers for your database must be available to the application server. You can skip this step if the drivers are already loaded.
   a. Copy the database driver JAR file into the lib directory. In Confluence Standalone this directory is /confluence/WEB-INF/lib. Other application servers will use a different path.
   b. If the application server does not support dynamic library loading, stop your application server.
3. Create a new Confluence home directory.
4. Open the WEB-INF/classes/confluence-init.properties file in your Confluence installation and change the confluence.home property to point to this new Confluence home directory.
5. Start up Confluence. Refer to the platform-specific installation instructions to learn how. You should be presented with the Confluence setup wizard. Enter your license information.
6. Select 'Custom install'.
7. Select a database from the drop down list.
8. Select Direct JDBC and then enter the username, password and database driver of the new database.
9. If you created a Confluence backup earlier and wish to restore it, import it into Confluence now.
10. Once the wizard is complete, if you did not check the 'Backup attachments', copy the backed up /attachments directory into the new Confluence home.

Troubleshooting External Database Connections

**Database Setup for PostgreSQL on Windows**

This guide was created on a Windows XP Service Pack 3 machine. Please check the Known Issues for PostgreSQL before you start.

**Installing PostgreSQL, Creating a User, and Creating a Database**

1. Obtain the PostgreSQL One Click Installer for Windows. Save it to your desktop.
2. Double click on the installer.

   ![Setup](image)

   **Setup - PostgreSQL**

   Welcome to the PostgreSQL Setup Wizard.

3. Choose a Data Directory.

5. Choose a password.
5. Select the port.

6. **Select the port.**

   **Password**

   Please provide a password for the database superuser and service account (postgres). If the service account already exists in Windows, you must enter the current password for the account.

   ![Password input fields]

   1. Choose a password for the 'postgres' account. This is the db root level account.

   ![Port selection input field]

   5432 is the default port. If you do change this number, please ensure that the new port does not conflict with any services currently running on that port and that you remember to update all further mentions of db port.

7. **Choose a Locale.**
8. Click 'Next'.

9. Wait for the installation to complete.
10. Skip Stack Builder.

11. Here's where to start the Admin tool.
12. Enter a password.

1. Double Click on Server

2. Enter 'postgres' password when prompted.

13. Make a new user.
14. Enter a name and password.

15. Create a new database.
16. Assign DB Owner permissions.

Setting up Confluence to use the PostgreSQL Database

At this point, you will need to download a JDBC driver from the PostgreSQL website for use with Confluence. You'll need the JDBC3 driver if you're using JDK 1.4 / JDK 1.5 and the JDBC4 driver for JDK 1.6.
Windows renames .jar extensions to .zip! Just rename it back to .jar. You'll have to set your folder options to view hidden file extensions if you can't rename it without changing the file type (Tools >> Folder Options >> View >> Uncheck "Hide Extensions for known file types."

If the server that is hosting the PostgreSQL database is not the same server as Confluence, then please ensure that the confluence server can contact the database server and also refer to the PostgreSQL documentation on how to set up pg_hba.conf if the pg_hba.conf file is not set properly, remote communication to the PostgreSQL server will fail.

1. Download Confluence Standalone, unzip it. (The directory into which you unzipped the Confluence installation is called the Confluence Installation directory. Next you will define the Confluence Home directory.)
3. Place the JDBC Driver into the <confluence-install-path>/confluence/WEB-INF/lib folder.
4. Start Confluence and after entering your license code on the Confluence Setup Wizard page, click 'Custom Installation'.
5. On the 'Choose a Database Configuration' page, select 'PostgreSQL' and click 'External Database'.
6. Click ‘Direct JDBC’.

7. Enter your PostgreSQL database setup details (defined above) as indicated below.

Running SQL Queries

For ongoing maintenance of your server, you can continue to use PGAdmin as your SQL browser.

Troubleshooting

If you are unable to connect to the database from Confluence and they are on different machines, most likely you have a firewall in between the two machines or your pg_hba.conf file is misconfigured. Verify that your firewall is set to allow connections through 5432 or double check your hba configuration.

If Confluence is complaining that it’s missing a class file, you might have forgotten to place the jdbc driver in the WEB-INF/lib folder or possibly have placed it in the wrong folder.

If none of the above describes your issue, please create a support ticket at http://support.atlassian.com and be sure to include your logs (found in confluence-install/logs and confluence-data/logs).

Database Setup For MySQL
Confluence should use an external database for production purposes, as the embedded database does not offer full transactional integrity in the event of sudden power loss. Confluence Standalone with MySQL is well-tested and easily configured for production purposes.

This page provides instructions for installing Confluence and the open-source MySQL database on Microsoft Windows and how to set up and configure MySQL to work with Confluence. Additional instructions are also provided for migrating across any existing Confluence database content. Use this guide in conjunction with the more general Database Setup Guide for Any Database. These instructions add some important reference notes specific to MySQL.

**Stage 1 - MySQL Database Setup**

1. **Install Confluence** if you have not done so already.

2. **MySQL 5.0** is supported since Confluence 2.5 and above.

3. Once the MySQL database server has been installed, run through the 'MySQL Server Instance Config Wizard':

   - At the start of the Config Wizard (or after having chosen Reconfigure Instance), choose Detailed Configuration.
   - Choose the type of MySQL Server that best suits your hardware requirements. This will affect the MySQL Server's usage of memory, disk and CPU resources. Refer to the relevant MySQL documentation for further information.
   - Choose Transactional Database Only for the database usage step. This ensures that your MySQL database will use InnoDB as its default storage engine. It is highly recommended that you only use the InnoDB storage engine with Confluence. Avoid using the MyISAM storage engine as this can lead to data corruption.
   - Set the InnoDB Tablespace settings to your requirements. (The default settings should be acceptable.)
   - For the networking options, ensure the Enable TCP/IP Networking option is selected (default) and that the Enable Strict Mode option is also selected (default). Refer to the MySQL documentation on setting the networking and server SQL modes for further information.
   - For the MySQL server instance's default character set option, choose Best Support For Multilingualism (i.e. UTF-8).
   - If you choose not to install the MySQL Server as a Windows Service, you will need to ensure that the database service has been started before running Confluence. If you choose to use one of the presets if desired or enter a number manually. Refer to the relevant MySQL documentation for further information.
   - Launch the MySQL Server automatically.
   - If you intend to connect Confluence to an existing, operational MySQL database server instance, we strongly recommend that you reconfigure this database server instance by running through the Config Wizard and initially choosing the Reconfigure Instance option.

4. **Download the latest MySQL Connector/J driver**, version 5.1 or newer.

5. **Extract the mysql-connector-java-5.x.y-bin.jar** file from the Connector J archive and place it in either the Confluence Installation Directory/lib or Confluence Installation Directory/conf/confluence/WEB-INF/lib directories. (The x.y depends on exactly which version you download – MySQL updates the version number from time to time.)

**Please note the following points:**

- Throughout the instructions below, the Confluence Installation Directory refers to the directory where you extracted the Confluence zipped installer.
- The MySQL Database Setup procedure below will make modifications to your default MySQL Server settings. These modifications result in:
  1. The default collation (localisation) option being changed to utf8_bin (that is, case-sensitive binary UTF8), such that by default, all new database tables will be created with this type of case-sensitive collation.
  2. The default MySQL database storage engine being changed to 'InnoDB'.

**Installation and Configuration**

Complete the following steps to install and configure Confluence and the MySQL Server:

1. **Install Confluence** if you have not done so already.

2. **MySQL 5.0** is supported since Confluence 2.5 and above.

3. Once the MySQL database server has been installed, run through the 'MySQL Server Instance Config Wizard':

   a. At the start of the Config Wizard (or after having chosen Reconfigure Instance), choose Detailed Configuration.
   b. Choose the type of MySQL Server that best suits your hardware requirements. This will affect the MySQL Server's usage of memory, disk and CPU resources. Refer to the relevant MySQL documentation for further information.
   c. Choose Transactional Database Only for the database usage step. This ensures that your MySQL database will use InnoDB as its default storage engine. It is highly recommended that you only use the InnoDB storage engine with Confluence. Avoid using the MyISAM storage engine as this can lead to data corruption.
   d. Set the InnoDB Tablespace settings to your requirements. (The default settings should be acceptable.)
   e. Choose Transactional Database Only for the database usage step. This ensures that your MySQL database will use InnoDB as its default storage engine. It is highly recommended that you only use the InnoDB storage engine with Confluence. Avoid using the MyISAM storage engine as this can lead to data corruption.
   f. Set the approximate number of concurrent connections permitted that best suits your Confluence usage requirements. You can use one of the presets if desired or enter a number manually. Refer to the relevant MySQL documentation for further information.
   g. For the networking options, ensure the Enable TCP/IP Networking option is selected (default) and that the Enable Strict Mode option is also selected (default). Refer to the MySQL documentation on setting the networking and server SQL modes for further information.
   h. For the MySQL server instance's default character set option, choose Best Support For Multilingualism (i.e. UTF-8).
   i. Launch the MySQL Server automatically.
   j. If you choose not to install the MySQL Server as a Windows Service, you will need to ensure that the database service has been started before running Confluence.
   k. If you choose not to install the MySQL Server as a Windows Service, you will need to ensure that the database service has been started before running Confluence.

4. **Download the latest MySQL Connector/J driver**, version 5.1 or newer.

5. **Extract the mysql-connector-java-5.x.y-bin.jar** file from the Connector J archive and place it in either the Confluence Installation Directory/lib or Confluence Installation Directory/conf/confluence/WEB-INF/lib directories. (The x.y depends on exactly which version you download – MySQL updates the version number from time to time.)
To create the database and user privileges:

1. Start the 'MySQL Administrator' application and enter your login credentials when prompted to connect to the MySQL database server.
   - If you ran through the 'MySQL Server Instance Config Wizard' in step 3 of the Installation and Configuration (above) and did not change your username, you should be able to connect to the MySQL database server using the default Username of 'root', Server Host of 'localhost' (assuming you are running MySQL Administrator on the same machine as the MySQL Server) and Password which you set in the Config Wizard.
   - If, however, you are running MySQL for the first time and you have not yet run through the Config Wizard, or you do not recall having set your login credentials, you should be able to click OK without a Username and Password.

2. Go to Service Control in the left pane and ensure that the MySQL Service is stopped. If not, click 'Stop Service' to stop the MySQL Service.

3. Go to Startup Variables in the left pane and click the 'Advanced' tab.

4. Ensure that the 'Default Collation' check box is selected, enter 'utf8_bin' for the 'Data Collation' value and click 'Apply changes'.
   - If you did not run through the 'MySQL Server Instance Config Wizard' in step 3 of the Installation and Configuration (above), click the 'General Parameters' tab and ensure that the Default storage check box has been selected with its value set to InnoDB.
   - Also, click the 'InnoDB Parameters' tab and ensure that the Activate InnoDB check box is selected. If not, implement these settings and click 'Apply changes' before proceeding.

5. Go back to Service Control in the left pane and click 'Start Service' to re-start the MySQL Service (with the updated default collation settings).

6. Go to Catalogs in the left pane, then right-click in the schema list at the bottom of this pane and select 'Create New Schema' from the pop-up menu.

7. Call the new Schema name 'confluence' and click 'OK'.

8. Go to User Administration in the left pane and then click 'Add new user' at the bottom of the window.

9. Enter the MySQL username 'confluenceuser'.
   - In fact, you can enter any legitimate MySQL username. However, the remaining steps and procedures on this page assume that you have entered the MySQL username of 'confluenceuser' at this point. If you choose a different MySQL username, substitute 'confluenceuser' in the remaining steps and procedures with your chosen MySQL username.

10. Enter and re-confirm a password for this user and click 'Apply changes'.

11. Right-click on the username 'confluenceuser' in the left pane and choose 'Add host from which the user can connect' from the pop-up menu.
   - If prompted to enable the global 'Show hosts in user list' option, choose 'Yes'.

12. Enter the host name 'localhost' and click 'OK'.

13. Click on 'localhost' within 'confluenceuser' in the left pane. (You might need to click on the name 'confluenceuser' first).

14. Click the 'Schema Privileges' tab and then click 'confluence' in the 'Schemata' list.

15. Make sure that 'confluenceuser@localhost' has all privileges assigned to them by clicking the '<-' button to move the privileges from the 'Available' to the 'Assigned' list and click 'Apply changes'.
   - To support international languages in Confluence, you should verify the newly created database is using UTF-8 encoding and re-examine the JDBC URL settings (configured in Stage 3).

Stage 2 - For Users With Existing Data Only

This stage is only required if you have existing Confluence content you wish to transfer:

1. Manually create an XML backup of Confluence under Administration -> Backup & Restore. If you have less than 100MB of attachments, check 'Backup attachments' when creating the backup. If you have over 100MB of attachments, you should not check the 'Backup attachments' and instead you should manually copy the /attachments directory in your Confluence home to another location. This attachments directory can then be copied into the new home directory as describe later.

2. Download the backup file to a backups folder.

Stage 3 - Database Connection Setup

To set up your Confluence MySQL database connection or to switch to using this external database:

1. Ensure that Confluence is stopped (for example, by ensuring that the application server instance or service which is running Confluence has been stopped or terminated).

2. Edit Confluence Installation Directory/confluence/WEB-INF/classes/confluence-init.properties and change the confluence.home property to point to a new directory, e.g. if you had
2. You could change it to:

```
confluence.home=c:/confluencedata_mysql
```

This is your new Confluence Home Directory. (The name doesn't have to end in _mysql – that's just an example)

3. Start Confluence and set up the new configuration.
   a. Enter your license key and click the 'Custom Installation' button.
   b. Under the 'External Database' heading, select 'MySQL' from the dropdown list and click 'External Database'.
   c. On the next page, click 'Direct JDBC'.
   d. Enter confluenceuser in the User Name field, and the password you chose earlier in the Password field.
   e. Click the Next button. If you get the error message 'Could not successfully test your database: Server connection failure during transaction. Due to underlying exception: 'java.sql.SQLException: Access denied for user 'confluenceuser'@'localhost' (using password: YES)' verify that you have properly given the confluenceuser user all the right permissions when connecting from localhost.

Stage 4 - For Users With Existing Data Only

To re-import your backup and plugin-cache:

1. At the 'Load Content' page, choose 'Restore From Backup', browse for the backup you created and restore it. Otherwise choose either the example or empty site as you wish.

2. Stop Confluence.

If you encounter any issues in setting up your MySQL database to work with Confluence, please refer to Known Issues for MySQL.

Known Issues for MySQL

Database Setup for Oracle

This guide covers deploying Confluence standalone 2.2 or later against an Oracle database, and is also applicable to the WAR distribution. For older Confluence versions, please follow these instructions.

This database can only be set up by an Oracle database administrator (DBA). If you are not a DBA, you should not attempt to set up this database.

Oracle has a history of being extremely difficult to set up. If you do not have access to an experienced Oracle DBA in your organisation, you are recommended to start with an alternative database and only consider migrating to Oracle after approval from their DBA. Atlassian’s technical support for Oracle setup difficulties will also reflect the high minimum skill requirements for attempting an Oracle setup.

**Database Setup Information**

This setup guide must be used in conjunction with the list of Known Issues For Oracle. Please review that page before continuing.

**Schema Requirements**

Confluence must be deployed to a schema in it’s own, separate Oracle instance. This avoids a Hibernate bug triggered by the existence of duplicate tablenames in other schemas, outlined [here](#).

**Database Incompatibilities**

Oracle 9i and later are supported, please upgrade any older versions prior to installing Confluence.

**Database driver update may be required**

For all versions of Oracle, you must upgrade to the latest 10g drivers. Check the latest [compatibility matrix](#) before proceeding to the JDBC download page. We highly recommend to use the thin drivers.

Please check that your version of Oracle does not have any known issues:
### Oracle Version | Oracle Driver | Issue | Solution
--- | --- | --- | ---
Any | Pre 10g | Driver incompatibilities | Upgrade to latest 10g drivers if compatible
Pre 9 | Any | Earlier DBs not compatible | Upgrade DB to 9.x or later
9.0.1.0 | Any | DB not compatible | Upgrade DB to 9.0.2.6 or later
10g | 10.1.0.3.0 | Drivers not compatible with Tomcat 5.5 | Upgrade drivers to 10.1.0.4.0 or later

You might also be interested in a [relevant JIRA documentation](https://confluence.atlassian.com) to check the compatibility of your Oracle server and driver.

### Deploying Against Oracle

Complete the instructions for [installing Confluence standalone](https://confluence.atlassian.com), then return to this document instead of proceeding to the Confluence Setup Guide.

### Database Preparation

Tailor these instructions to your particular database version:

1. Perform any necessary database or driver upgrades. Download the latest compatible database drivers.
2. Create a separate instance of Oracle and apply any configuration tasks.
3. Create a Confluence user configuration and grant access permissions.

### Adding a Datasource to Tomcat

1. Open `<INSTALL>/conf/server.xml` for editing.
2. Locate the section `<Host -> Context>`

```
<Host name="localhost" debug="0" appBase="webapps" unpackWARs="true" autoDeploy="false">
  <Context path="" docBase="..;/confluence" debug="0" reloadable="true">
    <!-- Logger is deprecated in Tomcat 5.5. Logging configuration for Confluence is specified in confluence/WEB-INF/classes/log4j.properties -->
    <Manager pathname="" />
  </Context>
</Host>
```

3. Paste in the `<Resource>` section provided, prior to `Manager` as shown:

```
<Host name="localhost" debug="0" appBase="webapps" unpackWARs="true" autoDeploy="false">
  <Context path="" docBase="..;/confluence" debug="0" reloadable="true">
    <!-- Logger is deprecated in Tomcat 5.5. Logging configuration for Confluence is specified in confluence/WEB-INF/classes/log4j.properties -->
    
    <Resource name="jdbc/confluence" auth="Container" type="javax.sql.DataSource" driverClassName="oracle.jdbc.driver.OracleDriver" url="jdbc:oracle:thin:@hostname:port:sid" username="<username>" password="<password>"><connectionProperties="SetBigStringTryClob=true" maxActive="25" maxIdle="5" maxWait="10000" /><Manager pathname="/" />
  </Context>
</Host>
```

4. Change the `username` and `password` to match the Oracle login.
5. Change `url` to match `hostname`, `port` and `sid` of the Oracle server. `sid` stands for the Schema ID. For example:

```
jdbc:oracle:thin:@example.atlassian.com:1521:confluencedb
```

For connecting to an Oracle RAC cluster, you’ll need to edit the connection string directly in `confluence.cfg.xml`, using Oracle’s connection syntax like this:
This example has been broken up over multiple lines for clarity, but it should be compacted into a single line when actually added to confluence.cfg.xml on your server.

6. If required, choose different maxActive and maxIdle values. These set how many total database connections will be allowed at one time, and how many will be kept open even when there is no database activity.

**Configure Confluence Datasource Access**

Confluence must be configured to use this datasource:

1. Edit the file `<INSTALL>/confluence/WEB-INF/web.xml`

2. Go to the end of the file and just before `</web-app>`, insert the following:

   ```
   <resource-ref>
   <description>Connection Pool</description>
   <res-ref-name>jdbc/confluence</res-ref-name>
   <res-type>javax.sql.DataSource</res-type>
   <res-auth>Container</res-auth>
   </resource-ref>
   ```

3. Locate the Oracle JDBC database drivers for JDK 1.4, which comes bundled with your database. We recommend using the thin drivers only. Copy `ojdbc14.jar` to the `<INSTALL>/common/lib` directory. This directory path is potentially `<INSTALL>/lib` if Confluence is running off Apache Tomcat version 6 or above.

**Confluence Setup Wizard**

Now Confluence is ready to attempt to connect to Oracle:

1. Startup Confluence using `<INSTALL>/bin/startup.bat` or `<INSTALL>/bin/startup.sh`

2. Insert your licence and select **External Database**.

3. Select **Datasource Connection** using your Oracle version.

4. Enter `java:comp/env/jdbc/confluence` for the name of the datasource.

Confluence should now deploy using the Oracle database specified. Please read this comment on Oracle database optimisation.

**Generic Oracle Configuration Tips**

**Websphere and Oracle**

If you are planning to run Confluence on a Websphere application server and Oracle database, you should read the information on Known Issues for Websphere.

**24-hour time format with Oracle 8i**

We have received a report from a user that when an Oracle 8i database is configured to use 24-hour time as the default format, an exception like this may occur:

```
jdbc:oracle:thin:@(DESCRIPTION=(SDU=32768)
(enable-broken)
(LOAD_BALANCE=yes)
(FAILOVER=yes)
(ADDRESS=
(PROTOCOL=TCP)
(HOST=dbserver1.example.com)
(PORT=1525))
(ADDRESS=
(PROTOCOL=TCP)
(HOST=dbserver2.example.com)
(PORT=1525))
(CONNECT_DATA=
(SERVICE_NAME=CONFDB)))
```
One symptom of this problem is that Confluence may refuse to start after midday.

The workaround is to go to 'General Configuration' and set the default time format to "HH:mm".

Known Issues For Oracle

Database Setup for Oracle (Pre Confluence 2.2)

This document is out of date

This documentation applies to Confluence 2.1.x or older. If you have Confluence 2.2.x or newer, please refer to Database Setup for Oracle.

Please note, we strongly recommend you install Confluence on a schema in a brand new database on your Oracle server. If this cannot be accommodated, be aware that Confluence may not install or operate properly. For more details on this limitation please see the issue filed here.

This installation assumes you are using the standalone distribution of Confluence and Oracle 9i. We have not tested against older versions of Oracle, but have been told that it should work against Oracle 8i provided you use the latest 9i drivers.

Note that some users have found that 9.0.1.0 does not work, while 9.0.2.6 does.

If you are using 10g you should use the 10.1.0.4.0 drivers – the 10.1.0.3.0 drivers don't work when using a Tomcat 5.5 datasource, as the connection returned is a T4CConnection instead of the OracleConnection which Spring is expecting.

1. Adding a datasource to Tomcat Versions before 5.5

   - Edit the conf/server.xml file in your Tomcat installation
   - Find the following lines:

   ```xml
   <Context path="" docBase="../confluence" debug="0" reloadable="true">
   <Logger className="org.apache.catalina.logger.FileLogger" prefix="atlassian-confluence." suffix=".log" timestamp="true"/>
   ```

   - Directly after the `<Logger.../>` line, (before the next `</Context>` line), insert the following:
You may want to choose different maxActive and maxIdle values: these are how many total database connections will be allowed at one time, and how many will be kept open even when there is no database activity.

- Replace the username and password parameters with the correct values for your database.
- In the url parameter, replace the word 'oracle-sid' with the name of the database your confluence data will be stored in. Obviously also change the hostname and port.

Versions 5.5 and later

In Tomcat 5.5 the configuration format has changed. The data source resource should be defined like this:

```xml
<Resource name="jdbc/Confluence" auth="Container" type="javax.sql.DataSource"/>
<ResourceParam name="jdbc/Confluence">
  <parameter>
    <name>Factory</name>
    <value>org.apache.commons.dbcp.BasicDataSourceFactory</value>
  </parameter>
  <parameter>
    <name>maxActive</name>
    <value>20</value>
  </parameter>
  <parameter>
    <name>maxIdle</name>
    <value>10</value>
  </parameter>
  <parameter>
    <name>maxWait</name>
    <value>10000</value>
  </parameter>
  <parameter>
    <name>username</name>
    <value>yourusername</value>
  </parameter>
  <parameter>
    <name>password</name>
    <value>yourpassword</value>
  </parameter>
  <parameter>
    <name>driverClassName</name>
    <value>oracle.jdbc.driver.OracleDriver</value>
  </parameter>
  <parameter>
    <name>url</name>
    <value>jdbc:oracle:thin:@hostname:port:oracle-sid</value>
  </parameter>
</ResourceParam>
```

- Copy the ojdbc14.jar to the common/lib directory (this jar is the oracle jdbc thin driver for JDK 1.4. It comes bundled with your Oracle 9i database). We recommend using the thin drivers only.

2. Configure the Confluence to be aware of this datasource

- Edit confluence/WEB-INF/web.xml in your confluence installation
- Go to the end of the file and just before </web-app>, insert the following:

```xml
<Resource name="jdbc/Confluence" auth="Container" type="javax.sql.DataSource">
  <ResourceParams name="jdbc/Confluence">
    <parameter>
      <name>factory</name>
      <value>org.apache.commons.dbcp.BasicDataSourceFactory</value>
    </parameter>
    <parameter>
      <name>maxActive</name>
      <value>25</value>
    </parameter>
    <parameter>
      <name>maxIdle</name>
      <value>5</value>
    </parameter>
    <parameter>
      <name>maxWait</name>
      <value>10000</value>
    </parameter>
  </ResourceParams>
</Resource>
```

3. Confluence setup wizard

- Startup confluence using bin/startup.bat or startup.sh
- Run through the setup process and when asked to choose a database type: choose Datasource Connection
• Enter in `java:comp/env/jdbc/confluence` for the name of the datasource and select the oracle 9 dialect.
• Complete the setup and that’s it!

Database Setup for SQL Server

Use this guide in conjunction with the more general Database Setup Guide for Any Database. These instructions add some reference notes specific to SQL Server.

1. Review Known Issues For SQL Server
2. Identify Character Encoding
   To identify which character encoding to use, check the encoding used by your application server and Confluence now. All three must use compatible encoding. For example, the default SQL Server encoding of USC-2 is compatible with UTF-8.
3. Create Database
   As an SQL administrator, create a new database. If you set your application server and Confluence to use an encoding incompatible with USC-2, specify that character encoding for the database.
4. Create SQL User Account
   As an SQL administrator, create a new user account for Confluence. Provide full create, read and write permissions for the table. Note that Confluence must be able to create its own schema.
5. Install Database Drivers
   SQL Server users are strongly recommended to install the jTDS JDBC drivers. These instructions add some reference notes specific to SQL Server.
   a. If using direct JDBC connection, copy the driver file `jtds-<version>.jar` into your standalone's `<confluence install>/WEB-INF/lib` directory.
   b. If you are configuring a datasource to connect to your MS SQL server database, you will need to place the jar file in `<confluence install>/lib` (for Confluence 2.10 onwards) or `<confluence install>/common/lib` (for earlier versions). You may find this page helpful: http://jtds.sourceforge.net/faq.html
6. Start Confluence and visit the home URL (eg http://localhost:8080) to start the Confluence Setup Wizard and select a Custom Install, insert the relevant connection information.
7. When prompted for a driver class name in the database setup step enter:
   ```
   net.sourceforge.jtds.jdbc.Driver
   ```
8. When prompted for the jdbc url, the format to use is:
   ```
   jdbc:jtds:sqlserver://<server>:<port>/<database>
   ```

Database JDBC drivers

Below you can find a link to the JDBC drivers for all currently supported databases. You will need to make the driver available to your application server.

JDBC driver download links -

- PostgreSQL - Download the JDBC 3 driver version specific to your PostgreSQL version
- MySQL
- Oracle
- DB2
- Microsoft SQL Server - Link goes to recommended jTDS JDBC drivers
- Sybase ASE

Creating Database Schema Manually

Database Schema Creation

This document provides information on how to find the SQL for database table creation.

Often, DBAs will require that table creation be done manually. To find the required SQL statements, you can use the script generated from our evaluation version's HSQLDB database.

- Install Confluence with no external database.
- Shut down Confluence.
- Find the file located in `<confluence-home>/database/confluencedb.script`.

The `confluence-home` directory is not your installation directory, the directory specified in `confluence-init.properties`. For more information, see Confluence Home Directory and Confluence Installation Directory.

To see some example SQL statements, click 'Tools' and select 'Attachments' on this wiki page.
To get Confluence to run against this established schema, configure the database with the normal procedure, then modify the hibernate.connection.url, username and password from `confluence-home/confluence.cfg.xml` or `server.xml`, depending on whether it's a direct jdbc or resource connection. This is described in Migrating Confluence Between Servers.

Database Configuration

**Known Issues For Supported Databases**

**Supported Databases**

See the List Of Supported Databases.

**Troubleshooting**

- Known Issues for Sybase Database
- Configuring Database Character Encoding
- Known Issues For SQL Server
- Known Issues for PostgreSQL
- Known Issues for Oracle
- Known Issues for DB2
- Known Issues for MySQL

**Configuring Database Character Encoding**

On this page:

- JDBC connection settings
  - MySQL
- Creating a UTF-8 database
  - MySQL
  - PostgreSQL
  - For PostgreSQL running under Windows
  - For PostgreSQL running under Linux
- Updating existing database to UTF-8
  - MySQL database with existing data
- Testing database encoding

The database used with Confluence should be configured to use the same character encoding as Confluence. The recommended encoding is Unicode UTF-8.

There are two places where character encoding may need to be configured:

- when creating the database
- when connecting to the database (JDBC connection URL or properties).

The configuration details for each type of database are different. Some examples are below.

**JDBC connection settings**

**MySQL**

Append `useUnicode=true` to your JDBC URL:

```
jdbc:mysql://hostname:port/database?autoReconnect=true&useUnicode=true&characterEncoding=utf8
```
If you are modifying confluence.cfg.xml directly rather than via the Confluence Installation GUI, you’ll need to escape out the & in the URL string as this is a reserved XML token and will break the confluence.cfg.xml syntax when the XML is parsed. An effective URL could be similar to:

```xml
<property
    name="hibernate.connection.url">jdbc:mysql://hostname:port/database?autoReconnect=true&amp;useUnicode=true&amp;characterEncoding=utf8</property>
```

### Creating a UTF-8 database

**MySQL**

1. Create a UTF-8 database with binary UTF-8 collation.
   
   - Binary UTF-8 provides case-sensitive collation.

   ```sql
   CREATE DATABASE confluence CHARACTER SET utf8 COLLATE utf8_bin;
   ```

2. You will also need to set the Server Character set to utf8. This can be done by adding the following in my.ini for Windows or my.cnf for other OS. It has to be declared in the Server section, which is the section after `[mysqld]`:

   ```ini
   [mysqld]
   default-character-set=utf8
   ```

3. Use the `status` command to verify database character encoding information.

   **Screenshot: Using the Status Command to Verify Database Character Encoding**

   ```sql
   mysql> CREATE DATABASE confluence CHARACTER SET utf8 COLLATE utf8_bin;
   Query OK, 1 row affected (0.02 sec)
   mysql> show databases;
   +--------------------+
   | Database           |
   +--------------------+
   | information_schema |
   | confluence         |
   | confluencedb       |
   | mysql              |
   | test               |
   +--------------------+
   5 rows in set (0.02 sec)
   mysql> use confluence;
   Database changed
   mysql> status;
   ```

4. In some cases, the individual tables collation and character encoding may differ from the one that the database as a whole has been configured to use. Please use the command below to ensure all tables within your Confluence database are correctly configured to use UTF-8 character encoding and binary UTF-8 collation:

   ```sql
   use confluence;
   show table status;
   ```

   Check for the value listed under the **Collation** column, to ensure it has been set to utf8_bin (that is, case-sensitive) collation for all tables.

   If not, then this can be changed by the following command, executed for each table in the Confluence database:
Please substitute the `<tablename>` above, with each table within the confluence database.

Relevant MySQL manual for more detailed explanation:

- Specifying Character Sets and Collations documentation.
- Connection Character Sets and Collations.
- SHOW TABLE STATUS Syntax.
- ALTER TABLE Syntax.

**PostgreSQL**

```
CREATE DATABASE confluence WITH ENCODING 'UNICODE';
```

Or from the command-line:

```
$ createdb -E UNICODE confluence
```

For more information see the PostgreSQL documentation.

**For PostgreSQL running under Windows**

Please note that international characters sets are only fully supported and functional when using PostgreSQL 8.1 and above under Microsoft Windows.

**For PostgreSQL running under Linux**

Warning: Please make sure you check the following to ensure proper handling of international characters in your database

When PostgreSQL creates an initial database cluster, it sets certain important configuration options based on the host enviroment. The command responsible for creating the PostgreSQL environment `initdb` will check environment variables such as `LC_CTYPE` and `LC_COLLATE` (or the more general `LC_ALL`) for settings to use as database defaults related to international string handling. As such it is important to make sure that your PostgreSQL environment is configured correctly before you install Confluence.

To do this, connect to your PostgreSQL instance using `psql` and issue the following command:

```
SHOW LC_CTYPE;
```

If `LC_CTYPE` is set to either "C" or "POSIX" then certain string functions such as converting to and from upper and lower case will not work correctly with international characters. Correct settings for this value take the form `<LOCALE>.<ENCODING>` (e.g. `en_AU.UTF8`).

If your `LC_CTYPE` is incorrect please check the PostgreSQL documentation for information on configuring database localisation. It is not easy to change these settings with a database that already contains data.

**Updating existing database to UTF-8**

**MySQL database with existing data**

Warning: Before proceeding with the following changes, please backup your database.

This example shows how to change your database from latin1 to utf8.

1. Dump the database to a text file using `mysqldump` tool from the command-line:
   ```
   mysqldump -p --default-character-set=latin1 -u <username> --skip-set-charset confluence > confluence_database.sql
   ```
2. Copy `confluence_database.sql` to `confluence_utf8.sql`
3. Open `confluence_utf8.sql` in a text editor and change all character sets from 'latin1' to 'utf8'
4. Encode all the latin1 characters as UTF-8:
   ```
   recode latin1..utf8 confluence_utf8.sql
   ```

In MySQL:

```
ALTER TABLE tablename CONVERT TO CHARACTER SET utf8 COLLATE utf8_bin;
```
1. DROP DATABASE confluence;
2. CREATE DATABASE confluence CHARACTER SET utf8 COLLATE utf8_bin;

Finally, reimport the UTF-8 text file:

1. mysql -u <username> -p --default-character-set=utf8 --max_allowed_packet=64M confluence < /home/confluence/confluence_utf8.sql

To support large imports, the parameter \`--max_allowed_packet=64M\` used above sets the maximum size of an SQL statement to be very large. In some circumstances, you may need to increase it further, especially if attachments are stored in the database.

Testing database encoding

See Troubleshooting Character Encodings for a number of tests you can run to ensure your database encoding is correct.

RELATED TOPICS:

- Character encodings in Confluence

### Known Issues for DB2

**On this page:**
- DB2 Does Not Support Unicode Character By Default
- DB2 Does Not Support Transaction Logging Of BLOBs Larger Than 1GB
- Configuring Database Character Encoding
- DB2 Dialect class change (if upgrading from Confluence version 2.2 or older)
- Encoding Test Problems
- Transaction Isolation Level of Read Uncommitted
- Incompatible Data Types on z/OS
- SQLCODE: -443, SQLSTATE: 38553, SQLERRMC: SYSIBM.SQLTABLES;TABLES;SYSIBM:CLI:-805

#### DB2 Does Not Support Unicode Character By Default

To support the Unicode character set, create your database like this:

For 8.2.2 or later:

```
db2 create database <name> using codeset utf-8 territory us pagesize 8 k
```

Before 8.2.2

```
db2 create database <name> using codeset utf-8 territory us
db2 create bufferpool bp8k <number of pages> pagesize 8 k
db2 create tablespace userspace1 pagesize 8 k managed by database using \(file \'<location>\'/\number of pages\'/\) bufferpool bp8k
```

The territory may not be important when using UTF-8, but it must be included.

#### DB2 Does Not Support Transaction Logging Of BLOBs Larger Than 1GB

"With their potentially large size, LOBs can slow down the performance of your database system significantly when moved into or out of a database. Even though DB2 does not allow logging of a LOB value greater than 1 GB, LOB values with sizes approaching 1 GB can quickly push the database log to near capacity. An error, SQLCODE -355 (SQLSTATE 42993), results from attempting to log a LOB greater than 1 GB in size. The lob-options-clause in the CREATE TABLE and ALTER TABLE statements allows users to turn off logging for a particular LOB column. Although setting the option to NOT LOGGED will improve performance, changes to the LOB values after the most recent backup are lost during roll-forward recovery."

> !important
> Although one could set the length for the CustomClobType in BodyContent.hbm.xml field length to larger sizes, say 2^31 to allow storing of BLOBs up to the size of 2 Gb, DB2 maximum length can only be set to 2^30, 1GB.

```
<property name="body" type="com.atlassian.confluence.core.persistence.hibernate.CustomClobType" update="true" insert="true" column="BODY" length="1073741824" />
```

**Configuring Database Character Encoding**
Refer to Configuring Database Character Encoding.

**DB2 Dialect class change (if upgrading from Confluence version 2.2 or older)**

If you are using DB2, and are upgrading Confluence from version 2.2 or older, the 'hibernate.dialect' property in the `confluence.cfg.xml` file needs to be changed to 'com.atlassian.hibernate.dialect.DB2Dialect' like so:

```
<property name="hibernate.dialect">com.atlassian.hibernate.dialect.DB2Dialect</property>
```

**Encoding Test Problems**

At the time of writing this, there is an open bug with the encoding test when using DB2. Details are here: CONF-8588.

**Transaction Isolation Level of Read Uncommitted**

Due to CONF-9323, DB2 requires a transaction isolation level of "read uncommitted" to avoid occasional deadlocks. The more concurrent usage a Confluence instance experiences, the higher the frequency of deadlocks with a transaction isolation level higher than "read uncommitted".

Set the following property in the `confluence.cfg.xml` file.

```
<property name="hibernate.connection.isolation">1</property>
```

**Incompatible Data Types on z/OS 8**

There are problems when running DB2 on z/OS 8 and 9. This platform is not officially supported but there is an unsupported workaround here.

**SQLCODE: -443, SQLSTATE: 38553, SQLERRMC: SYSIBM.SQLTABLES;TABLES;SYSIBM:CLI:-805**

... 23 more
```

You might encounter this problem after an upgrade to UDB Version 8.1 FixPak 10 (also known as Version 8.2 FixPak 3) when invoking a DB2 Call Level Interface (CLI) catalog function. The solution to this is to perform a rebind of the `db2schema.bnd` file locally against each database. Refer to the IBM Technote FAQ for more instruction.

Interpreting DB2 error codes

Interpreting DB2 error codes

When DB2 dies, it'll dump its error codes out in the SQL Exception:

```
DB2 SQL error: SQLCODE: -803, SQLSTATE: 23505
```

You can find the meaning of the error code from the db2 command prompt with "? sqlxxxx" where xxxx is the SQLCODE from the error
message:

[db2inst1@matilda db2inst1]$ db2 ? sql-803

SQL0803N One or more values in the INSERT statement, UPDATE statement, or foreign key update caused by a DELETE statement are not valid because the primary key, unique constraint or unique index identified by "<index-id>" constrains table "<table-name>" from having duplicate rows for those columns.

Explanation:

The INSERT or UPDATE object table "<table-name>" is constrained by one or more UNIQUE indexes to have unique values in certain columns or groups of columns. Alternatively, a DELETE statement on a parent table caused the update of a foreign key in a...

(and so on for about three more pages of text...)

You may also like to use the SQL Message Finder to find information about iSeries SQL messages. You can search by message ID, SQLCODE, or SQLSTATE value. You can also select an SQLSTATE class code.

There is also an online reference for SQL Messages and Codes which is quite useful.

Known Issues for MySQL

On this page:

- No 'toLower' Capability - Database Case Sensitivity
- Configuring Database Character Encoding
- MySQL Storage Engine
  - Upgrading to Confluence 3.0 or later fails
- MySQL JDBC Drivers
- Access Denied
- Max Allowed Packet Size Exceeded
  - Prior MySQL 4.0, use this syntax instead:
  - From MySQL 4.0, use this syntax
- Duplicate Key Exception During Import
  - Setting the MySQL Collation to be case sensitive
- Database Timeout Issues when creating a Manual Backup
- After a while, database errors are generated and Confluence stops working
- Troubleshooting Tips

This page provides tips on configuring MySQL as Confluence's database.

**No 'toLower' Capability - Database Case Sensitivity**

Some of the database indices are not available for MySQL. See Creating a Lowercase Page Title Index for more detail on a workaround.

**Configuring Database Character Encoding**

To prevent problems with character encoding, for consistency, we recommend to use Unicode character encoding UTF-8 among all the entities of your system. See Configuring Database Character Encoding for more details.

When specifying a character encoding as part of your mysql connection url (eg: &characterEncoding=utf8), it is important to ensure that the specified encoding is compatible with the default encoding used by your database. Note: if you do not specify a characterEncoding on the connection url, the connection will default to the server's default character set.

Full details of MySQLs character support is available here: http://dev.mysql.com/doc/mysql/en/charset.html

**MySQL Storage Engine**

The default storage engine for MySQL is MyISAM. Because this storage engine does not support referential integrity, foreign key constraints or transactions, using it may lead to data corruption. Some known issues caused by using MyISAM include CONF-16070 and CONF-16494. Hence, this storage engine is not recommended for use with Confluence.

For a MySQL command line session, you can set the storage engine by passing the --default-storage-engine=INNODB option when starting the session. You can make this the default MySQL Server setting by adding this option to the my.ini (or my.cnf) configuration file.

For more information, please refer to: http://dev.mysql.com/doc/refman/5.1/en/storage-engines.html
**Upgrading to Confluence 3.0 or later fails**

Some customers running Confluence on a MySQL database may find that when they upgrade to Confluence 3.0 or later, their Confluence 3.0 upgrade fails, with the Confluence logs revealing a "Specified key was too long" error. This issue is known to occur when MySQL’s MyISAM storage engine and UTF-8 character set is used with Confluence.

If this is the case, please refer to the Upgrade to Confluence 3.0 with MySQL database fails with messages like "specified key was too long" knowledge base article on how to resolve this upgrade issue.

**MySQL JDBC Drivers**

Ensure that you are using the latest (5.1) MySQL Java Connector. Earlier versions of the MySQL connector have a bug which is triggered by improvements in Confluence 2.2. These earlier connector versions will result in an error being recorded in your logs on upgrade (and will result in unstable operation of Confluence).

You can download the latest MySQL connector from the MySQL Java Connector 5.1 download page. Please be sure that you remove any older versions of the connector from your application server.

Don't use the debug version of these drivers (the jar file ending in '-g.jar'). This requires extra configuration, see Installing the Driver and Configuring the CLASSPATH

**Access Denied**

If you get a connection error: Access denied for user 'confluenceuser'@'localhost.localdomain' to 'localhost.localdomain' in your environment. Create a user 'confluenceuser@localhost%' to match any domain starting with localhost.

**Max Allowed Packet Size Exceeded**

A common problem with MySQL is the max packet size restriction, which can result in an "Object Error" message when installing certain plugins.

If you are using MySQL 4 and prior, you may come across a problem with max_allowed_packet size.

To resolve these problems, you need to either specify or increase the value for max_allowed_packet. Make sure to set the packed size when starting the server, not the client.

**Prior MySQL 4.0, use this syntax instead:**

```
shell> mysqld --set-variable=max_allowed_packet=16M
```

In MySQL 3.23, the largest possible packet is 16MB, due to limits in the client/server protocol. In MySQL 4.0.1 and up, the limit is 1GB.

**From MySQL 4.0, use this syntax**

```
shell> mysqld --max_allowed_packet=32M
```

For more information, please refer to MySQL manual: http://dev.mysql.com/doc/refman/5.0/en/packet-too-large.html

If you use MySQL Administrator, you can set this parameter from the Startup Variables section on Windows OS (Options on MacOS) > Advanced Networking subsection. You can set max_allowed_packet option to 16 (MB), which in the screenshot below, is currently set at 1 MB.

**Screenshot: Setting the max_allowed_packet option via the MySQL Administrator**
Duplicate Key Exception During Import

When upgrading to MySQL from another database, such as HSQL, importing the site backup often fails with an error like this:

```
Duplicate key or integrity constraint violation message from server:
```

Such errors occur because usually MySQL evaluates unique key constraints and primary key constraints in a case insensitive way. So if you have a space with the key "sp" and another with the key "SP", MySQL will refuse to add the second one.

This problem is avoidable by setting the `collation` on the database to be case sensitive.

Setting the MySQL Collation to be case sensitive

MySQL uses collations for sorting data and for evaluating uniqueness.

To set the collation to case sensitive when using utf8, use this command:

```
CREATE DATABASE confluence CHARACTER SET utf8 COLLATE utf8_bin;
```

Note: The collation must be compatible with the character set. The name of the database in the example is confluence.

For further information see the MySQL documentation on character sets on collations.

Database Timeout Issues when creating a Manual Backup

A problem that some customers have encountered is their Database connection timing out whilst in the middle of performing a Manual Site Backup in Confluence.

This issue is indicated in the log files with the following Error Message:

```
com.mysql.jdbc.CommunicationsException: Communications link failure due to underlying exception:
```

According to the MySQL manual:

```
The number of seconds the server waits for activity on a non-interactive connection before closing it. This timeout applies only to TCP/IP and Unix socket file connections, not to connections made via named pipes, or shared memory.
```

```
On thread startup, the session wait_timeout value is initialized from the global wait_timeout value or from the global interactive_timeout value, depending on the type of client (as defined by the CLIENT_INTERACTIVE connect option to mysql_real_connect()). See also interactive_timeout.
```

This problem is resolved by adjusting the `wait_timeout` parameter to a higher value.

If problems persist after making the changes, switch to the Alternative Backup Strategy.

After a while, database errors are generated and Confluence stops working

MySQL's JDBC drivers usually close a connection that remains idle for a certain amount of time (normally eight hours). Since Confluence uses a connection pool, this means that pooled connections will be terminated if they are not used within a certain time period.

The solution is to append `?autoReconnect=true` to the end of your database's JDBC URL.

- If you are using JNDI data-sources, you will do this in your application server's configuration files.
If you have configured Confluence to access the database directly, you will need to manually edit the `hibernate.connection.url` property in the `confluence.cfg.xml` file in your `confluence.home` directory. After you have changed the URL in this file, restart Confluence.

**Troubleshooting Tips**

The following are tips for Troubleshooting MySQL.

- Cannot Restore XML Backup due to Data Truncation - MySQL Driver 3.1
- Setup Fails Creating MySQL Schema due to Tomcat Incompatibility
- Upgrade to Confluence 3.0 with MySQL database fails with messages like "specified key was too long"
- MySQL Table is Marked as Crashed and Should be Repaired
- Cannot Create XML Backup due to Corrupt Table
- Error loading plugins or saving content larger than 1Mb
- Login after a long inactivity on confluence fails using MySQL
- Characters appear as question marks using MySQL
- ClientAbortException java.net.SocketException Broken Pipe with Jira User management on MySQL
- Database errors when using MySQL and MyISAM tables
- Error- Invalid use of group function

**Known Issues For Oracle**

- Use Oracle with thin Oracle 10g JDBC drivers
- Running Confluence on Websphere with Oracle database
- 24-hour time format with Oracle 8i
- ORA-01430: column being added already exists in table
- Configuring Database Character Encoding
- Knowledge Base Articles

**Use Oracle with thin Oracle 10g JDBC drivers**

We recommend you to use the following configuration to run Confluence with Oracle:

- Regardless of what version of the Oracle database you are using, you should use the Oracle 10g JDBC drivers. (Note: Oracle 10g JDBC drivers will not work with Oracle 8.1.6 see Oracle FAQ)
- We highly recommend to use the thin drivers.

Also see:

**Running Confluence on Websphere with Oracle database**

If you are planning to run Confluence on a Websphere application server and Oracle database, you should read the information on Known Issues for Websphere.

**24-hour time format with Oracle 8i**

We have received a report from a user that when an Oracle 8i database is configured to use 24-hour time as the default format, an exception like this may occur:
One symptom of this problem is that Confluence may refuse to start after midday.

The workaround is to go to 'General Configuration' and set the default time format to "HH:mm".

ORA-01430: column being added already exists in table

If any of confluence tables exist in other oracle schemas in the "same database", those tables will not be created, impairing bits of Confluence functionality that depend on those table(s).

This issue has been filed in CONF-3613.

There is a work around however as found by one of our customers:

```sql
CREATE VIEW wiki_dev.all_objects AS
SELECT *
FROM sys.all_objects
WHERE owner = 'WIKI_DEV';
```

Configuring Database Character Encoding

Refer to Configuring Database Character Encoding.

Database Setup for Oracle

Known Issues for PostgreSQL

Database Performance Issue on PostgreSQL 7

There is an issue in versions of PostgreSQL prior to 8.0 that causes the database to do a full table scan rather than an index lookup for many of the database queries performed by Confluence. This will cause Confluence to slow significantly the more data it has stored.
While we fully support Confluence on PostgreSQL 7, we highly recommend upgrading to version 8.0 or higher for this reason.

Configuring Database Character Encoding

Refer to Configuring Database Character Encoding.

Incorrect JDBC Driver Used

If you have downloaded and used an incorrect JDBC Driver version, you will see this error when you attempt to setup the Database connection in the Setup Wizard:

```
java.lang.UnsupportedClassVersionError: Bad version number in .class file
at java.lang.ClassLoader.defineClass1(Native Method)
at java.lang.ClassLoader.defineClass(Unknown Source)
at java.security.SecureClassLoader.defineClass(Unknown Source)
at org.apache.catalina.loader.WebappClassLoader.findClassInternal(WebappClassLoader.java:1847)
at org.apache.catalina.loader.WebappClassLoader.findClass(WebappClassLoader.java:873)
at org.apache.catalina.loader.WebappClassLoader.loadClass(WebappClassLoader.java:126)
at org.apache.catalina.loader.WebappClassLoader.loadClass(WebappClassLoader.java:1205)
at java.lang.ClassLoader.loadClassInternal(Unknown Source)
at java.lang.Class.forName0(Native Method)
at java.lang.Class.forName(Unknown Source)
at com.atlassian.confluence.setup.actions.SetupStandardDatabaseAction.execute(SetupStandardDatabaseAction.java:22)
at com.opensymphony.xwork.DefaultActionInvocation.invoke(DefaultActionInvocation.java:168)
```

You will need to download the correct JDBC Driver based on your PostgreSQL Database Version and also the JDK you are using. Below is a guide to selecting the correct JDBC version from PostgreSQL's website:

Many other versions of the JDBC driver are available. This includes development versions, compatibility with older JDKs, and previous versions of the driver.

To determine JDK/JVM compatibility this following list matches up versions of the JVM with the JDBC specification implemented:

- JDK 1.1 - JDBC 1. Note that with the 8.0 release JDBC 1 support has been removed, so look to update your JDK when you update your server.
- JDK 1.2, 1.3 - JDBC 2.
- JDK 1.3 + J2EE - JDBC 2 EE. This contains additional support for javax.sql classes.
- JDK 1.4, 1.5 - JDBC 3. This contains support for SSL and javax.sql, but does not require J2EE as it has been added to the J2SE release.
- JDK 1.6 - JDBC4. Support for JDBC4 methods is limited. The driver builds, but the majority of new methods are stubbed out.

There is also a matrix on the page which lists all supported versions for the respective PostgreSQL database versions.

Download PostgreSQL JDBC Drivers

Known Issues For SQL Server

Due to numerous reported performance issues with SQL Server 2000, it is strongly recommended that you use SQL Server 2005 instead. SQL Server 2000 is not supported. Confluence with SQL Server 2005 is known to not work very well under high load environments. Please see the deadlock issues below

- Database Deadlock Issues
- Unicode Characters Not Supported By Default
- SQL Server 2005 and Case-Sensitive Schema Objects.
- Case-Sensitive Collation
  - Setting up a New Confluence Instance
  - Migrating an Existing Confluence Instance to a Different Database
- Use jTDS Driver 1.0.3 or Later for JDBC Connection - Reason 1
- Use jTDS Driver 1.0.3 or Later for JDBC Connection - Reason 2
- Configuring Database Character Encoding
- Setting up Authentication Mode of the SQL Server
- Moving from One SQL Server to Another
  - Known Issues

Database Deadlock Issues
Problem

When creating a page, you may encounter deadlocks and get the following error:

```
2008-11-11 17:01:21,355 ERROR [http-8080-Processor6] [sf.hibernate.util.JDBCExceptionReporter]
logExceptions Transaction (Process ID 55) was deadlocked on lock resources with another process
and has been chosen as the deadlock victim. Rerun the transaction.
-- url: /confluence/pages/docreatepage.action | userName: tstcreator3 | action: docreatepage
```

Reason

SQL Server is escalating row locks (in this case deleting a draft from the CONTENT table) to table locks and stopping other transactions from accessing the table.

Solution

Configure your database to use the isolation level, Read Committed with Row Versioning. You can do this by executing the following query:

```
ALTER DATABASE <database name>
SET READ_COMMITTED_SNAPSHOT ON
WITH ROLLBACK IMMEDIATE;
```

More information on SQL Server isolation levels can be found in the Microsoft documentation.

From version 2.10.x onwards, indexes will be automatically created upon performing an upgrade.

For customers using a previous version, please execute the following DDL against your confluence database:
Unicode Characters Not Supported By Default

Problem
Non-ASCII characters will not be displayed by Confluence.

Reason
The default SQL Server dialect uses column types that do not support Unicode, specifically the `char`, `varchar` and `text` column types. See CONF-4786 for details.

Solution
To add Unicode support, use the Unicode SQL Server dialect which uses `nchar`, `nvarchar` and `ntext` column types. Unicode SQL Server dialect has the downside of halving the maximum length of each column from 8000 characters to 4000, as every char is stored in two bytes.

Enable Unicode SQL Server dialect on a new setup, perform these steps prior to 'Stage 3 - Database Connection Setup' of the Database Setup For Any External Database:

1. Open the `confluence installation folder/confluence/WEB-INF/classes/database-defaults/mssql.properties` file within your Confluence installation folder. In version 2.6 onwards, this file is located in the `/confluence/WEB-INF/lib/confluence.x.x.x.jar` file. Jar files are similar to zip formats, so you may need to extract the `mssql.properties` file and place it in `confluence/WEB-INF/classes/database-defaults`. You can create the `database-defaults` directory if it does not exist.
2. Comment the line: `dialect=net.sf.hibernate.dialect.SQLServerDialect`
3. Uncomment the line: `#dialect=net.sf.hibernate.dialect.SQLServerIntlDialect`
4. Start the Confluence Setup Wizard

For existing SQL Server instances wishing to enable Unicode support:

1. From Confluence, create an XML site backup
2. From your DBA tool, create a full backup of the Confluence schema contents
3. Stop Confluence
4. Move your home directory
5. Drop all tables from the Confluence schema
6. Change the dialect to Unicode using the above instructions
7. Follow the 'Stage 3 - Database Connection Setup' of Database Setup For Any External Database to setup the connection again and import the XML backup
8. Once the Setup Wizard is complete, stop Confluence
9. Copy any customised content and plugins from your old home directory into the new home directory
10. Start Confluence

This will not restore previously stored Unicode characters.

SQL Server 2005 and Case-Sensitive Schema Objects.

A default installation of SQL Server 2005 on a Windows system configured for English will be case sensitive for schema objects. That is to say that a table called 'CONTENT' is not the same as a table called 'content'.

Confluence will not run correctly in this case. During installation of SQL Server, be sure to choose a case-insensitive schema.

Case-Sensitive Collation

'Collation' refers to a set of rules that determine how data is sorted and compared. Case sensitivity is one aspect of collation. Other aspects include sensitivity to kana (Japanese script) and to width (single- versus double-byte characters).

Case-sensitive or case-insensitive collation — how should you create your Confluence database? What about when you are migrating your existing Confluence instance from one database to another?

Setting up a New Confluence Instance

For new Confluence instances, we recommend using case-sensitive collation for your Confluence database, which is the default collation type used by many database systems. The Confluence application itself reduces all usernames into lower-case characters before they are stored in the Confluence database. Therefore, 'joebloggs', 'joebloggs', 'JoeBloggs', etc. will be treated as the same username on a Confluence installation with case-sensitive database collation.

Migrating an Existing Confluence Instance to a Different Database

The default Confluence Standalone configuration uses case-sensitive database collation. This is often the case with databases on several other systems which were created under default conditions. Therefore, if you are migrating from this type of configuration to a new database, we recommend that the new database uses case-sensitive collation. If you use case-insensitive collation, you may encounter data integrity problems after migration (for example, via an XML import) if data stored within your original Confluence site required case-sensitive distinctions.
Information on different collation options in SQL Server 2005 can be found in the Microsoft documentation.

**Use jTDS Driver 1.0.3 or Later for JDBC Connection - Reason 1**

**Problem**

When using jTDS driver 1.0.2 or earlier, Confluence may freeze when performing certain functions, and you see a warning like the one displayed below:

```
[ERROR] ActionSupport - \An error occurred while storing the requested page!\n<org.springframework.jdbc.UncategorizedSQLException: (Hibernate operation): encountered SQLException
\[The amount of data read from the stream is not = length.\]; nested exception is java.sql.SQLException: The amount of data read from the stream is not = length.>
```

This can occur with jTDS driver 1.0.2 but is fixed in 1.0.3 - see the jTDS homepage. It will prevent backups from succeeding and lock access to the database when viewing certain pages.

**Solution**

Upgrade to jTDS driver 1.0.3 or later from the jTDS download page.

**Use jTDS Driver 1.0.3 or Later for JDBC Connection - Reason 2**

**Problem**

When using MS SQL Server without the jTDS drivers, you may receive an error similar to:

```
Caused by: java.sql.SQLException: [Microsoft]\[SQLServer 2000 Driver for JDBC\]ResultSet can not re-read row data for column 2.
```

We use a component in Confluence called Hibernate. According to Hibernate Documentation there may be issues with the Microsoft JDBC drivers resulting in the error you are seeing.

**Solution**

Upgrade to jTDS driver 1.0.3 or later from the jTDS download page. You may also consider alternative SQL Server drivers listed on the Hibernate page.

**Configuring Database Character Encoding**

When creating the database schema, the database character encoding must be compatible with the application and Confluence character encoding as described in Configuring Database Character Encoding. If setting MS SQL to use UTF-8 is not an option, you can create a schema that uses UCS-2 encoding, and have the application and Confluence use UTF-8 encoding.

**Setting up Authentication Mode of the SQL Server**

During a login process to SQL server or while setting up your DB connection through the Setup Wizard, the following error may appear:
Login failed for user 'username'. The user is not associated with a trusted SQL Server connection. (Microsoft SQL Server, Error: 18453).

The cause of this error is that the SQL server has been configured to operate in 'Windows Authentication Mode (Windows Authentication)' and doesn't allow the use of SQL accounts.

In order to resolve this problem, change the Authentication Mode of the SQL server from 'Windows Authentication Mode (Windows Authentication)' to 'Mixed Mode (Windows Authentication and SQL Server Authentication)'.

Please refer to this Microsoft document for more details.

**Moving from One SQL Server to Another**

In Confluence, tables are created using the database login name for the schema instead of the dbo owner. Thus when moving data from one SQL server to another, you need to ensure that you create the database user first before exporting and importing the data, otherwise that user cannot be created.

To illustrate with an example, say the Confluence database login was 'confuser' — the table names would be 'confuser.table1', 'confuser.table2', etc.

When performing a database backup and restore into the new server, the tables will still be 'confuser.table1' and 'confuser.table2'. However, if the database user 'confuser' has not been created first on the new server then you can no longer access the tables with a login of 'confuser', because although the database was copied across, the login object was not. You cannot create the login with the same name at this stage as it will complain that there is already an object in the database with the same name (the user object).

**Known Issues**

- Database Deadlock on Microsoft SQL Server
- Invalid Username or Password when Delegating User Management to use JIRA Logins
- Invalid object name hibernate_unique_key due to Invalid Table Name
- Unicode Characters Not Supported By Default
- Use jTDS Driver 1.0.3 or Later for JDBC Connection

**Known Issues for Sybase Database**

*Find below a list of tips relating to using Sybase with Confluence*

Confluence and JIRA shared user base management fails due to wrong casing of database columns and names.

- See Override properties in JIRA to Confluence Bridge

**Configuring Database Character Encoding**

Refer to Configuring Database Character Encoding

**Case sensitivity issues**

All versions of Confluence 2.3 require a patch in order to work with Sybase. This is downloadable from http://jira.atlassian.com/browse/CONF-7925.

**Improving Database Performance**

**Diagnosis**

Use native database tools to assess the impact of your database. If you’d like to check what Confluence is doing from it’s side, you can enable sql loggin. If you analyze thread dumps, as this is done in general Troubleshooting Confluence Hanging or Crashing guide, you may find the kinds of threads like this:
These threads are waiting for a database connection. It could be that the database is not performing optimally, or it may just need tuning for allowing more connection threads. Both are discussed below.

**Upgrade your Database and Drivers**

SQL Server 2000, Oracle 9i, and MySQL with 3.1 drivers are among some of the issues with database performance. Ensure you are using updated versions of databases and their drivers.

**Ensure you have the Latest Database Indices**

Confluence has improved database performance over time. You'll want to make sure you have all the latest, if you're getting hung threads waiting for db connections.

**Confluence 2.10 or Manual .ddl Indices**

With 2.10 and later, Confluence includes database indices bundled. Confluence 2.10 automatically creates the necessary database indexes when you upgrade. If you are not on 2.10, you may have run the ddl manually during the upgrade process. To check, you can look against these.

**Additional Indices not Included in 2.10**

- One import db index is the **lower case page title index**. Prior to Confluence 3.0, querying for a page by title and space key can take a long time due to table scans necessary on a lowercase where clause. On most databases it is possible to add a lowercase index on these columns that helps with performance. See [Creating a Lowercase Page Title Index](#) for instructions on how to do this. Prior to 2.10, apply lowercase title indexes (all Confluence versions).
- The compound database title index for the ATTACHMENTDATA table is described in [CONF-13819](#).
- A composite index on some of the columns in SpacePermissions table is described in [CONF-14488](#).

**Tuning the Database Connection Pool**

This is described in the knowledge base article [Confluence Slows and Times out During Periods of High Load due to DB Connection Pool](#).

**Configure a Database Query Timeout**

If a database is getting overloaded, you can prevent it from crashing Confluence by [Configuring a Database Query Timeout](#).

**Related Articles**

Troubleshooting Database Issues.

**Creating a Lowercase Page Title Index**

**Diagnosis**

Confluence sometimes has performance problems retrieving pages by title because the query uses the lower() function. For example, the query looks something like this:

```
select * from CONTENT where lower(TITLE) = :title and SPACEID = :spaceid
```

Database profiling might show a query like the following taking a long time to execute (emphasis added):

```
select ... from CONTENT page0_, SPACES space1_
where page0_.CONTENTTYPE='PAGE'
and ((lower(space1_.SPACEKEY)= @P0 and page0_.SPACEID=space1_.SPACEID)
and(lower(page0_.TITLE)= @P1 )
and(page0_.PREVVER is null )and(page0_.CONTENT_STATUS='current')
```

Typically, databases don't use indexes when you use a function in a where clause; they do a table scan instead. This makes the performance of this query not ideal ([CONF-11577](#)).

**Generic solution**

On many databases (e.g. Oracle, PostgreSQL, DB2 for z/OS), it is possible to create the index using the normal "create index" syntax, just using the function instead of the column name.

```
create index CONFTITLE_LOWER on CONTENT(lower(TITLE));
```

Sources:
- http://www.postgresql.org/docs/current/static/sql-createindex.html
- http://asktom.oracle.com/tkyte/article1/

**SQL Server**

On SQL Server, you can add a computed column to the database table and then add an index on this column.

```
alter table CONTENT add TITLE_LOWER as lower(TITLE);
create index CONFTITLE_LOWER on CONTENT(TITLE_LOWER);
```

Sources:

**MySQL**

It is not currently possible to create a lowercase index on MySQL. Confluence 3.0 includes some caching improvements which should alleviate this performance problem on this database.

Source:

Workaround for MySQL databases, using a case-insensitive collation:

Please check whether your MySQL database has been set to use case-sensitive or case-insensitive collation. The queries to check whether your database is set to case-insensitive collation are:

```
show full columns from content where field = 'title';
show full columns from spaces where field = 'spacekey';
```

If the `collation_name` is returned as `<encoding>_ci ci`, the `ci` indicates case-insensitive collation.

If the database has been set to use case-insensitive collation, you can try removing `lower` from the following queries, in your `ContentEntityObject.hbm.xml` file residing in your `<Confluence-Install>/confluence/WEB-INF/lib/confluence-2.x.x.jar/com/atlassian/confluence/core/`:

```
<query name="confluence.page_findLatestBySpaceKeyTitle"> <![CDATA[
from Page page
where lower(page.space.key) = :spaceKey and
lower(page.title) = :pageTitle and
page.originalVersion is null and
page.contentStatus = 'current'
]]> </query>

<query name="confluence.page_findLatestBySpaceKeyTitleOptimisedForComments"> <![CDATA[
from Page page
left join fetch page.comments as theComments
left join fetch theComments.children
where lower(page.space.key) = :spaceKey and
lower(page.title) = :pageTitle and
page.originalVersion is null and
page.contentStatus = 'current'
]]> </query>
```

**DB2 for Linux, Unix or Windows**

DB2 supports indexes on generated columns which are used for queries with a matching predicate. You can implement it like this:

```
ALTER TABLE CONTENT ADD COLUMN TITLE_LOWER GENERATED ALWAYS AS (LOWER(TITLE));
CREATE INDEX CONFTITLE_LOWER ON CONTENT(TITLE_LOWER)
```

Troubleshooting External Database Connections

The Atlassian Database Check Utility

A common administration issue when configuring Confluence is identifying database connectivity problems. The helper JSP can isolate database connectivity issues. It simply checks whether you can connect to a database with your application server. If your application server cannot connect to the database, Confluence certainly will not.

Purpose:

- Check that your application server can successfully query your database (either via immediate JDBC connectivity or a Datasource in the context of your application server).
- Pinpoint problems in your configuration which may occur if the above is failing.

Functionality:

- Check that a JDBC Driver can be loaded into memory and view what is already loaded.
- Connect to a JDBC URL and do a 'select 1' from the database.
- Find a DataSource in the JNDI environment and do the above.
- View the System classpath (to ensure that the JDBC jar file is there).

Using the Utility

If you have already setup Confluence completely

1. Download testdatabase.jsp to 'MY-CONF-INSTALL-PATH/confluence'
2. Restart Confluence
4. Check that your database driver is loaded into memory. If not, check the system classpath for the JDBC driver file, and that the driver is in the <confluence-install>/lib folder (for Confluence version 2.10 onwards) or <confluence-install>/common/lib (for earlier versions) as per these instructions.
5. Enter the DB settings Confluence is using and test the database. If an error appears, check that the db service is running, the location matches, and that any users specified actually exist with the right login and permissions. You may be able to find a workaround by googling the error.

If you cannot setup Confluence because of an error in 'Configuring Database'

1. Record the DB settings you are using for your direct JDBC or datasource connection in the 'Configure Database' step of your setup
2. Download testdatabase.jsp to 'MY-CONF-INSTALL-PATH/confluence'
3. Rename 'MY-CONF-INSTALL-PATH/confluence/WEB-INF/web.xml' to 'backup web.xml' (This disables redirection)
4. Restart Confluence
5. Go to http://MY-CONF-SERVER:MY-CONF-PORT/testdatabase.jsp
6. Check that your database driver is loaded into memory. If not, check the system classpath for the JDBC driver file, and that the driver is in the confluence-install/common/lib folder as per the instructions
7. Enter the DB settings you recorded and test the database. If an error appears, check that the db service is running, the location matches, and that any users specified actually exist with the right login and permissions. You may be able to find a workaround by googling the error.
8. After correcting the error, rename 'MY-CONF-INSTALL-PATH/confluence/WEB-INF/backup web.xml' back to 'web.xml'

Notes

This JSP is bundled in Confluence 1.2.4 and onwards. It can be used with earlier versions quite easily. If you use this utility, please let us know ways in which we could improve it or leave helpful hints for others here.

For a comprehensive set of database manual that might be helpful for troubleshooting, please refer to the following links:

- PostgreSQL
- MySQL

Request Technical Support

If you're still stuck after attempting the suggestions above, lodge a free technical support request with information on your database setup.
Configuring database query timeout

If database queries are taking too long to perform, and your application is becoming unresponsive, you can configure a timeout for database queries. There is no default timeout in Confluence.

To configure a database query timeout, do the following on your test server:

1. Shut down Confluence.

2. Extract `databaseSubsystemContext.xml` from the `confluence-x.x.x.jar` that is in `confluence/WEB-INF/lib/`, and put a copy in `confluence/WEB-INF/classes/`.

3. Edit `confluence/WEB-INF/classes/databaseSubsystemContext.xml` to add the `defaultTimeout` property to the `transactionManager` bean:

   ```xml
   <bean id="transactionManager" class="org.springframework.orm.hibernate.HibernateTransactionManager">
       <property name="sessionFactory">
           <ref bean="sessionFactory"/>
       </property>
       <property name="defaultTimeout" value="120"/>
   </bean>
   ```

The timeout is measured in seconds and will forcibly abort queries that take longer than this. In some cases, these errors are not handled gracefully by Confluence and will result in the user seeing the Confluence error page.

4. Start Confluence.

Once the timeout is working properly in your test environment, migration the configuration change to Confluence.

⚠️ You will need to reapply these changes when upgrading Confluence, as the original `databaseSubsystemContext.xml` file changes from version to version.

Troubleshooting the Embedded Database (hSQL DB)

java.sql.SQLException: User not found: SA

Also see http://hsqldb.sourceforge.net/doc/guide/ch01.html#N101C2.

HSQLDB periodically must update its files to represent changes made in the database. In doing so, it must delete the current `confluencedb.data` file on the filesystem (beneath `conf.home/database`) and replace it with a new one.

If an administrator issues a shutdown on Confluence in this period, data can be lost, and is typically noticed by the error message, when starting Confluence up again, of 'User not found: SA'.

Users encountering this problem should seek to restore backups, contained in the backup directory beneath `confluence.home`. If daily backups have been turned off, and no other copy of data remains, the data is lost.

.annotatorNote

HSQLDB should not be used as a production database. It is included for evaluation purposes only.

Hibernate logging

It can be useful to enable detailed Hibernate logging when debugging problems with HSQL.

Connecting to the Embedded Database

Connecting to the Embedded HSQL Database can be quite difficult. You may need to connect to the database to retrieve information, or for troubleshooting purposes.

Please follow the instructions on how to you can connect to the embedded HSQL Database using the free Database Administration Tool DBVisualizer.

Connecting to HSQLDB using DBVisualizer

The purpose of this guide is to walk you through connecting to Confluence's embedded Hypersonic SQL Database using the Database Administration tool DBVisualizer.

Below are step by step instructions on how to Configure DBVisualizer and connect it to HSQLDB.

Prerequisites

1. Download and install the latest copy of DBVisualizer.
2. You will also need to download a copy (preferably the latest version) of HSQLDB
3. Extract the contents of the HSQLDB archive
4. Ensure that Confluence is not running.

Connection Procedure

Please ensure that you read and follow the instructions below carefully.

⚠️ Remember to backup your <confluence-home>/database folder before attempting any modifications

1. Enter Connection Name

   1. Click on the icon highlighted in Red
   2. Enter an identifiable name for the connection. e.g. conf2.5.4-std

2. Select JDBC Driver

   Select Database Driver

   - HSQLDB embedded

   Select the appropriate database driver from the list above.

   The selected driver has not been properly configured yet. Press Load Driver Files button to open a file chooser in which you should select the driver file(s). If multiple files must be loaded then hold CTRL and select all of them at once. Driver files are normally packaged as JAR or ZIP files. In addition you can load a directory with driver classes.

   1. From the drop down list select HSQLDB Embedded
   2. Click on Load Driver Files
   3. Browse to directory where the HSQLDB.jar file is located

3. Select Database Path
1. Browse to your `<Confluence-Home>` directory
2. Open the Database folder
3. Select the `confluencedb.properties` file

4. Enter Connection Details

1. Remove the ".properties" from the end of `confluencedb`
2. Type in `sa` for the username
3. Leave the password field blank

*refer to the example screenshot above if you are unsure*

5. Connect to embedded Database

1. Click on Test Connection to verify that the details are correct.
2. Click on "Finish" to complete the setup
3. Select the connection from the list on the left hand side.
4. You can now click on "Connect" to connect to the embedded database.
HSQldb database manager

Alternatively, you can use HSQldb's database manager. Just copy the value of hibernate.connection.url in confluence.cfg.xml as the URL and you're good to go.

Database Tables Reference

Below is a diagram of the Table References in Confluence (2.5.4).

This may be useful for Database Administrators that need to manually create the Database tables.

Upgrading From HSQL 1.7.1 to 1.8

If you have received an error message while upgrading Confluence which said "HSQldb Database needs to be cleaned. Please run HSQL17To18PreUpgradeCleaner.", and referred you to this page, you need to do the following:

1. Shut down Confluence
2. Open a command window.
3. Change your directory to the directory you set as your confluence.home directory.
4. Execute the following command: java -jar <confluence install directory>/hsqlcleaner/hsqlcleaner.jar
5. Start Confluence -- the upgrade will now work.

Don't run this unless asked to by Confluence - it won't work

Guide to using Apache Tomcat's Virtual Hosts

Introduction

Sometimes it is necessary to have Tomcat serve different applications on the same context path, but different host names. Most commonly, this is when trying to use a simple mod_proxy configuration with Apache.

Tomcat configuration

Tomcat allows name-based virtual hosting, where the hostname of the request determines which application processes it. The following configuration shows how two virtual hosts can be configured for Jira and Confluence on the same Tomcat instance:

| Confluence application server URL | http://confluence-app-server.internal.example.com:8080/ |
| JIRA application server URL      | http://jira-app-server.internal.example.com:8080/ |

Below is a minimal configuration of Tomcat's server.xml which configures separate hosts for Jira and Confluence on the URLs above.
Points to note:

- the HTTP connector is accessible on port 8080, as per the URLs above
- the AJP connector is not included in this minimal configuration. If you want to use mod_jk with this configuration, you need to ensure you add it.
- in the Engine, the Confluence host is configured as the default host. The default host is used if the request doesn't contain a Host header, or is accessed by a name the server doesn't recognise.
- because the above configuration uses name-based virtual hosting, you need to have entries in your DNS server for "confluence-app-server" and "jira-app-server" that point to the application server

More information

After doing this, you can configure Apache virtual hosts to map subdomains like jira.example.com and confluence.example.com to your application.

How to dump Active Directory data to a file

You can extract all the data present in your Active Directory onto a file using the following command (please ensure you are logged in with sufficient rights to do this)

```
csvde -f test.csv
```

This command will perform a CSV dump of every entry in your Active Directory server. You should be able to see the full DN's of users and groups.

Known Issues with Enterprise or Webhosting environments

When you attempt to run Confluence, you may get the following error:

```java
java.security.AccessControlException: access denied (java.lang.RuntimePermission
accessDeclaredMembers)
    at java.security.AccessControlContext.checkPermission(AccessControlContext.java(Compiled Code))
    at java.security.AccessController.checkPermission(AccessController.java(Compiled Code))
    at java.lang.SecurityManager.checkPermission(SecurityManager.java(Compiled Code))
```

Some of the libraries Confluence relies on to function make use of features of the Java language that may be restricted by Java security policies. This does not normally cause any problems: the default security configuration of most application servers will happily run Confluence. However, in some shared-hosting or enterprise environments, security settings may be such that Confluence can not function.

The permissions required by Confluence to run are detailed in the sample policy file below. You may need to give this information to your systems administrator so that they can be deployed with the Confluence application.
Managing Application Server Memory Settings

The minimum and maximum JVM heap space allocated to the application server affects performance. Confluence administrators may wish to modify this value from the defaults depending on their server load. This document only provides guidelines rather than rules, so administrators optimising for performance should use this document as a starting point only.

Testing For Optimum Memory Settings

Bigger is not always better for heap size. When optimising memory settings, consider starting by setting the minimum heap size to 1/4 the available physical memory on the server and setting the maximum to 1/2 of the maximum heap. Avoid setting the minimum and maximum to be the same since server load is normally variable. Being able to use less memory under low load results in slightly improved performance as garbage collections can be made smaller.

Testing Resources

- Enable the `verbosegc` JVM parameter to assist in determining the memory size that minimises overall garbage collection
- Use Page Request Profiling to gauge end-user performance

Determine Minimum Memory

Experiment with setting a lower minimum such as 1/10 of the maximum heap. Identify how much memory is required while under minimum load and set the minimum to that value. It is important to have Confluence use the minimum memory necessary, because garbage collection performance is dependent on the memory usage. Having an unnecessarily high minimum memory setting will degrade performance during GC operations.

Determine Maximum Memory

Experiment with different maximum memory settings with the `verbosegc` JVM parameter enabled to determine GC performance. Memory usage is most likely to be maximised under peak load, and when creating a site XML backup, Atlassian recommends disabling the XML backup and using the Alternative Backup Strategy.

- If you normally perform manual XML site backups on your server, test your maximum memory requirements by performing a site XML backup while the server is under maximum load
- If you do not create manual XML site backups, simply monitor the server while under maximum load

The maximum memory should be the total memory while in this state plus a buffer of at least 15%, taking into account how your garbage collection performs. Never set maximum memory to a value above 85-90% of the available physical server memory as this results in disk paging. Always leave 10-15% of available physical server memory unallocated to allow for OS background processes.

Applying Memory Settings

Users of the EAR/WAR distribution set their memory in their application server. For Confluence Standalone, the heap space is set in the Confluence install directory.

- Windows users edit `TOMCAT_HOME/bin/setenv.bat`
- Other OS users edit `TOMCAT_HOME/bin/setenv.sh`

If you are running Tomcat as a Windows service, you may need to run a `regedt32` to increase memory as in the article on increasing JIRA memory. Although the article discusses JIRA, it should also be applicable to Confluence.

The relevant parameter is

```
JAVA_OPTS="-Xms256m -Xmx1024m"
```

Where `-Xms` is the minimum and `-Xmx` is the maximum memory available to Apache Tomcat. In this sample the maximum memory has been set to 1024 megabytes, but you will have to figure out the best setting based on your particular environment.

Note: In newer Tomcat distributions the file may not exist. Feel free to create it in the `/bin` directory.

Additional Suggestions

- ```
grant codeBase "file:${catalina.home}/webapps/confluence/-" {
    permission java.security.AllPermission;
};
grant {
    permission java.lang.RuntimePermission "accessDeclaredMembers";
    permission java.lang.reflect.ReflectPermission "suppressAccessChecks";
    permission java.lang.RuntimePermission "defineCGLIBClassInJavaPackage";
};
```
Upgrade to Java 6
Java 6 has some better reporting when it comes to memory management, also Java 5 is almost out of life for Sun as Java 6 has been out for quite some time (over 2 years!). If upgrading to 6 is not an option, upgrading to a more recent Java 5 is highly recommended, there is an Java 5 update 15 (they are running a BETA of update 8).

Tune the garbage collector
There is a very overly complicated document on tuning the garbage collector on Java 6 (Java 5 version). This document will probably be a bit overwhelming, the only thing that really could be experimented with is selecting a different collector as the default one can cause system pauses while it finds collectible memory.

Make memory sizes equal
If you set the initial memory allocation size (-Xms) and the max memory allocation size (-Xmx) the same you can reduce overhead in the JVM because it doesn't need to resize the memory. This doesn't always result in performance improvements though.

PermGen Memory
The Permanent Generation Size -XX:MaxPermSize=128m could be increased but only really needs to be if they experience OutOfMemoryErrors which are reported to be PermGen full errors. 128m does seem a little low for this, especially on a 64bit JVM, but increasing it won't directly affect performance (just stopping a crash when it fills up).

Stack Size
Setting the stack size (-Xss) is ok, but can result in the JVM requiring more memory. Decrease it if you are running out of heap.

Pull down RSS Feeds or use the Repository plugin through a web proxy
You will need to make Confluence aware of your proxy.

Running Confluence behind Apache

Introduction
Running Confluence behind a web server should be done for performance reasons in high-load environments. In general, web server caching and thread management is far superior to that provided by your application server's HTTP interface.

To run Confluence behind the Apache httpd web server, there are two main configuration options: mod_jk or mod_proxy.

<table>
<thead>
<tr>
<th>Connection type</th>
<th>Features</th>
</tr>
</thead>
</table>
| mod_proxy (also known as reverse proxy) | • recommended connection method  
• simple HTTP proxy to application server  
• works with all application servers  
• if application paths are consistent, there is minimal load on the web server |
| mod_jk (also known as AJP) | • uses the AJP binary protocol  
• provides failover (and load balancing, which Confluence supports only with a clustered license)  
• only works with some application servers (typically Tomcat)  
• if application paths are consistent, there is some load on the web server to translate requests to AJP |

Features common to both mod_proxy and mod_jk
- application paths must be consistent to avoid complex and slow URL rewriting  
- works with name-based virtual hosting, both on web server and app server  
- web server keeps a pool of connections to application server

Mod_proxy documentation
- Using Apache with mod_proxy is the main documentation for this configuration.
If you want to set up the common configuration of JIRA and Confluence virtual hosts, you can use Apache's virtual hosts with separate application servers, then Tomcat's virtual hosts to run both applications on a single instance of Tomcat.

**Mod_jk documentation**

- Using Apache with mod_jk is the main documentation for this configuration.
- You can follow a similar method to the mod_proxy documentation above for setting up virtual hosts in Apache and Tomcat, if required.

**Mod_jk2 not supported**

The misleadingly-named mod_jk2 is an older method of connecting to Tomcat from Apache. Since mod_jk2 is no longer supported by the Apache Foundation, we do not support this configuration, and are not updating our mod_jk2 documentation. Mod_jk2 also has unresolved problems with Unicode URLs; you need to use either mod_proxy or mod_jk for international characters to work correctly in Confluence.

**Other related documentation**

- Apache and Apache Connector Tips
- Using the (older) mod_jk2 connector
- Configuring Tomcat's URI encoding
- Adding SSL for Secure Logins and Page Security

**General Apache Configuration Notes**

On this page:

- Prefer Apache mod_deflate to Confluence's built-in gzip implementation
- Ensure keepalive is enabled
- Enable keepalive for recent MSIE user agents

**Prefer Apache mod_deflate to Confluence’s built-in gzip implementation**

1. Disable gzip in confluence. See Compressing an HTTP Response within Confluence.
2. Enable gzip compression in Apache. For RedHat distributions this can be achieved by adding the following lines:

```
AddOutputFilterByType DEFLATE text/html text/plain text/xml text/css application/x-javascript
#
# ensure sensible defaults
DeflateBufferSize 8192
DeflateCompressLevel 4
DeflateMemLevel 9
DeflateWindowSize 15
```

**Ensure keepalive is enabled**

```
KeepAlive On
```

**Enable keepalive for recent MSIE user agents**

The standard Apache SSL configuration is very conservative when it comes to MSIE and SSL. By default all keepalives are disabled when using HTTPS with MSIE. While MSIE will always be special, the issues with SSL and MSIE have been solved since Service Pack 2 for Windows XP, released over 4 years ago. For anyone using an XP machine below SP2, it is safe to allow keepalive for MSIE 6 and above.

Remove the following lines:

```
SetEnvIf User-Agent ".*MSIE.*" nokeepalive ssl-unclean-shutdown
BrowserMatch "MSIE [1-4]" nokeepalive ssl-unclean-shutdown
```

Add these in their place:

```
BrowserMatch "MSIE [1-4]" nokeepalive ssl-unclean-shutdown downgrade-1.0 force-response-1.0
BrowserMatch "MSIE [5-9]" ssl-unclean-shutdown
```

Running Confluence behind Apache
Using Apache with mod_jk

Introduction

The Apache web server is often used in front of an application server to improve performance in high-load environments. Mod_jk allows request forwarding to an application via a protocol called AJP. Configuration of this involves enabling mod_jk in Apache, configuring a AJP connector in your application server, and directing Apache to forward certain paths to the application server via mod_jk.

Mod_jk is sometimes preferred to mod_proxy because AJP is a binary protocol, and because some site administrators are more familiar with it than with mod_proxy.

The scope of this documentation is limited to configuring the AJP connector in Tomcat 5.x. Other application servers may support AJP connectors; please consult your application server documentation for instructions on how to configure it.

The configuration below assumes your Confluence instance is accessible on the same path on the application server and the web server. For example:

<table>
<thead>
<tr>
<th>Externally accessible (web server) URL</th>
<th><a href="http://www.example.com/confluence/">http://www.example.com/confluence/</a></th>
</tr>
</thead>
<tbody>
<tr>
<td>Application server URL (HTTP)</td>
<td><a href="http://app-server.internal.example.com:8080/confluence/">http://app-server.internal.example.com:8080/confluence/</a></td>
</tr>
</tbody>
</table>

The AJP connection of the application server is set to: app-server.internal.example.com:8009.

Configuring mod_jk in Apache

The standard distribution of Apache does not include mod_jk. You need to download it from the JK homepage and put the mod_jk.so file in your Apache modules directory.

```
# Put this after the other LoadModule directives
LoadModule jk_module modules/mod_jk.so

# Put this in the main section of your configuration (or desired virtual host, if using Apache virtual hosts)
JkWorkersFile conf/workers.properties
JkLogFile logs/mod_jk.log
JkLogLevel info
JkMount /confluence worker1
JkMount /confluence/* worker1
```

Configuring workers.properties

Create a new file called 'workers.properties', and put it in your Apache conf directory. (The path for workers.properties was one of the configuration settings above.)

```
worker.list=worker1
worker.worker1.host=app-server.internal.example.com
worker.worker1.port=8009
worker.worker1.type=ajp13
```

Tomcat 5.x configuration

In Tomcat 5, the AJP connector is enabled by default on port 8009. An absolutely minimal Tomcat server.xml is below for comparison. The relevant line is the Connector with port 8009 – make sure this is uncommented in your server.xml.
Points to note:

- the Connector on port 8009 has protocol of "AJP/1.3". This is critical.
- the Context path of the Confluence application is "/confluence". This must match the path used to access Confluence on the web server.
- we recommend keeping your application Contexts outside the server.xml in Tomcat 5.x. The above example includes them for demonstration only.

**Improving the performance of the mod_jk connector**

The most important setting in high-load environments is the number of processor threads used by the Tomcat AJP connector. By default, this is 200, but you should increase it to match Apache's maxThreads setting (256 by default):

```
<Connector port="8009" minSpareThreads="5" maxThreads="256" protocol="AJP/1.3" />
```

All the configuration parameters for the AJP connector are covered in the Tomcat documentation.

**Ensuring UTF-8 compatibility**

If you have problems downloading attachments with non-ASCII characters in the filename, add the following to your Apache configuration:

```
JkOptions +ForwardURICompatUnparsed
```

And specify UTF-8 as the URIEncoding in the AJP connector configuration:

```
<Connector port="8009" protocol="AJP/1.3" URIEncoding="UTF-8" />
```

These settings are discussed further on Configuring Tomcat's URI encoding.

**More information**

The [Tomcat JK website](http://tomcat.apache.org-doc) has complete documentation on workers.properties and Apache configuration. You can also find information there on how to use mod_jk with IIS.

**Alternatives**

If you’re not happy with mod_jk, or find it too difficult to configure, you can:

- use [mod_proxy](http://httpd.apache.org/docs/2.2/mod/mod_proxy.html), which works with any application server, and together with mod_proxy_html allows complex URL rewriting to deal with different application paths on the web server and the application server.

**Using Apache with mod_proxy**

This page describes how to integrate Confluence into an Apache website, using mod_proxy. There are some common situations where you might do this:

- You have an existing Apache-based website, and want to add Confluence to the mix (eg. [http://www.example.com/confluence](http://www.example.com/confluence)).
- You have two or more Java applications, each running in their own application server on different ports, eg. [http://localhost:8080/confluence](http://localhost:8080/confluence) and [http://localhost:8081/jira](http://localhost:8081/jira). By setting up Apache with mod_proxy, you can have both available on the regular HTTP port (80), eg. at [http://www.example.com/confluence](http://www.example.com/confluence) and [http://www.example.com/jira](http://www.example.com/jira). If you are running JIRA and Confluence, we recommend this setup. It allows each app to be restarted, managed and debugged separately.
This page describes how to configure mod_proxy. We describe two options:

- If you want a URL like http://www.example.com/confluence/, go to the simple configuration.
- If you want a URL like http://confluence.example.com/, go to the complex configuration.

Simple configuration

Set the context path

First, set your Confluence application path (the part after hostname and port) correctly. Say you want Confluence available at http://www.example.com/confluence/, and you currently have it running at http://localhost:8080/. The first step is to get Confluence available at http://localhost:8080/confluence/.

To do this in Tomcat (bundled with Confluence), edit conf/server.xml, locate the "Context" definition:

```
<Context path="" docBase="../confluence" debug="0" reloadable="true"/>
```

and change it to:

```
<Context path="/confluence" docBase="../confluence" debug="0" reloadable="true"/>
```

Then restart Confluence, and ensure you can access it at http://localhost:8080/confluence/

Configure mod_proxy

Now enable mod_proxy in Apache, and proxy requests to the application server by adding the example below to your Apache httpd.conf (note: the files may be different on your system; the JIRA docs describe the process for Ubuntu/Debian layout):

```
# Put this after the other LoadModule directives
LoadModule proxy_module /usr/lib/apache2/modules/mod_proxy.so
LoadModule proxy_http_module /usr/lib/apache2/modules/mod_proxy_http.so

# Put this in the main section of your configuration (or desired virtual host, if using Apache virtual hosts)
ProxyRequests Off
ProxyPreserveHost On

<Proxy */>
    Order deny,allow
    Allow from all
</Proxy>

ProxyPass /confluence http://localhost:8080/confluence
ProxyPassReverse /confluence http://localhost:8080/confluence
<Location /confluence>
    Order allow,deny
    Allow from all
</Location>
```

Note to Windows Users

It is recommended that you specify the absolute path to the mod_proxy.so and mod_proxy_http.so files.

Set the URL for redirection

You will need to modify the server.xml file in your tomcat's conf directory and set the URL for redirection.

Locate this code segment

```
<Connector port="8080" maxHttpHeaderSize="8192"
    maxThreads="150" minSpareThreads="25" maxSpareThreads="75"
    enableLookups="false" redirectPort="8443" acceptCount="100"
    connectionTimeout="20000" disableUploadTimeout="true"/>
```

And append the following segment:
Replace www.example.com with the URL you wish to be redirected to.

Complex configuration

A complex configuration involves using the mod_proxy_html filter to modify the proxied content en-route. This is required if the Confluence path differs between Apache and the application server. For example:

<table>
<thead>
<tr>
<th>Externally accessible (Apache) URL</th>
<th><a href="http://confluence.example.com/">http://confluence.example.com/</a></th>
</tr>
</thead>
<tbody>
<tr>
<td>Application server URL</td>
<td><a href="http://app-server.internal.example.com:8080/confluence/">http://app-server.internal.example.com:8080/confluence/</a></td>
</tr>
</tbody>
</table>

Notice that the application path in the URL is different in each. On Apache, the path is /, and on the application server the path is /confluence.

For this configuration, you need to install the mod_proxy_html module, which is not included in the standard Apache distribution. Alternative solutions are discussed below.

The ProxyHTMLURLMap configuration can become more complex if you have multiple applications running under this configuration. The mapping should also be placed in a Location block if the web server URL is a subdirectory and not on a virtual host. The Apache Week tutorial has more information how to do this.

More information

- The mod_proxy_html site has documentation and examples on the use of this module in the complex configuration.
- Apache Week has a tutorial that deals with a complex situation involving two applications and ProxyHTMLURLMap.
- Using Apache with virtual hosts and mod_proxy shows how to configure the special case where you want JIRA and Confluence running on separate application servers on virtual host subdomains.

Alternatives

If Tomcat is your application server, you have two options:

- use mod_jk to send the requests to Tomcat
- use Tomcat's virtual hosts to make your Confluence application directory the same on the app server and the web server, removing the need for the URL mapping.
If your application server has an AJP connector, you can:

- use mod_jk to send the requests to your application server.

**Using Apache with virtual hosts and mod_proxy**

**Introduction**

The Apache web server is often used in front of an application server to improve performance in high-load environments. Mod_proxy simply redirects requests for certain URLs to another web server, so it typically requires no additional configuration on the application server.

This page documents a very common configuration request: configuring JIRA and Confluence on two Apache virtual hosts, running on different application servers. This is just a special case of mod_proxy configuration.

You can use virtual hosts in your application server if you want to run JIRA and Confluence on the same application server. There is a sample configuration for Tomcat you can use after configuring Apache.

**Apache configuration**

For this configuration to work properly, the application paths must be the same on both the application servers and the web server. For both JIRA and Confluence below, this is /.

<table>
<thead>
<tr>
<th>JIRA external URL</th>
<th><a href="http://jira.example.com/">http://jira.example.com/</a></th>
</tr>
</thead>
<tbody>
<tr>
<td>JIRA application server URL</td>
<td><a href="http://jira-app-server.internal.example.com:8080/">http://jira-app-server.internal.example.com:8080/</a></td>
</tr>
<tr>
<td>Confluence external URL</td>
<td><a href="http://confluence.example.com/">http://confluence.example.com/</a></td>
</tr>
<tr>
<td>Confluence application server URL</td>
<td><a href="http://confluence-app-server.internal.example.com:8080/">http://confluence-app-server.internal.example.com:8080/</a></td>
</tr>
</tbody>
</table>

Add the following to your Apache httpd.conf:

```html
# Put this after the other LoadModule directives
LoadModule proxy_module /usr/lib/apache2/modules/mod_proxy.so
LoadModule proxy_http_module /usr/lib/apache2/modules/mod_proxy_http.so

# Put this with your other VirtualHosts, or at the bottom of the file
NameVirtualHost *
<VirtualHost *>
  ServerName confluence.example.com
  ProxyRequests Off
  <Proxy>*</Proxy>
  Order deny,allow
  Allow from all
</VirtualHost>

ProxyPass / :8080/http://confluence-app-server.internal.example.com
ProxyPassReverse / :8080/http://confluence-app-server.internal.example.com
<Location>
  Order allow,deny
  Allow from all
</Location>
</VirtualHost>

<VirtualHost *>
  ServerName jira.example.com
  ProxyRequests Off
  <Proxy>*</Proxy>
  Order deny,allow
  Allow from all
</VirtualHost>

ProxyPass / :8080/http://jira-app-server.internal.example.com
ProxyPassReverse / :8080/http://jira-app-server.internal.example.com
<Location>
  Order allow,deny
  Allow from all
</Location>
</VirtualHost>
```

Points to note:

- ProxyPass and ProxyPassReverse directives send traffic from the web server to your application server.
- The application path is the same on the application server and on the web server (both are /).
- Because the above configuration uses name-based virtual hosting, you must configure your DNS server to point both names (jira.example.com, confluence.example.com) to your web server.
More information

For different ways to configure mod_proxy, see Using Apache with mod_proxy.

If you use Tomcat, mod_jk provides a different way of connecting Apache via AJP. You can also use the above configuration with just one application server if you use Tomcat’s virtual hosts.

Setting up Confluence with IIS

This page describes how to install Confluence Standalone with IIS using the Apache jk connector.

IIS is not a supported application server, as we do not test releases against it. The instructions below are for information only, and are published with the intention of sharing the knowledge we’ve acquired.

If you encounter problems with IIS, please bear in mind that our expertise with IIS is limited and that you should contact Microsoft for support.

If you are using JIRA as well as Confluence, please see this document instead.

On this page:
- Step 1. Install IIS
  - IIS 6
  - IIS 7
- Step 2. Install Confluence Standalone
- Step 3. Configure Tomcat
- Step 4. Configure the Tomcat Connector
- Step 5. Connect Confluence with IIS

Step 1. Install IIS

If you are running Windows Server 2003, you will only be able to use IIS 5.1 or 6. If you are using Windows Server 2008, you might like to install IIS 7.

**IIS 6**

If you are using Windows Server 2003 or XP professional, follow these instructions for installing IIS 6.

After installation is complete you should be able to go to http://localhost/iishelp/iis/misc/default.asp in your browser and see the IIS Getting Started page.

**IIS 7**

Similar to the previous Windows versions, IIS is not installed by default in Windows Server 2008 so you need to install it manually.

1. Start your Server Manager.
2. Click 'Roles'.
3. In the right hand panel, click "Add Roles".
4. A new window will pop up. Select the 'Web Server (IIS)' option.
5. Click 'Next' until you see another set of checkbox options to install the required 'Roles Services' for the web server (IIS).
6. Scroll down to 'Application Development' and tick the following:
   - CGI
   - ISAPI Extensions
   - ISAPI Filters
7. Click 'Next'.
8. And lastly, click 'Install'.

To check that IIS has been installed successfully, you can direct your browser to http://localhost/ and see the IIS 7 logo.

You can learn more about IIS 7 from this website.

Step 2. Install Confluence Standalone

Do a normal Confluence installation, after which you should be able to use confluence as usual through the URL http://localhost:8080.

Step 3. Configure Tomcat

Add another connector to your server.xml file, directly after the existing <Connector ... /> tag:
Restart Confluence.
In the logs/catalina.YYYY-MM-DD.log file you should see the Jk is running:

```
INFO: Starting Coyote HTTP/1.1 on http-8080
INFO: JK: ajp13 listening on /0.0.0.0:8009
7/09/2006 14:40:04 org.apache.jk.server.JkMain start
INFO: Jk running ID=0 time=0/31&nbsp;config-null
```

Step 4. Configure the Tomcat Connector

These instructions are based on the Tomcat Connector, IIS Configuration documentation.

1. Download the isapi_redirect.dll from the apache tomcat download page - click ‘browse download area’ to search for the file.
   * For example, you will find the win32 binaries here: http://apache.wildit.net.au/tomcat/tomcat-connectors/jk/binaries/win32/
   and if the current version is 1.2.27, you will download this file: http://apache.wildit.net.au/tomcat/tomcat-connectors/jk/binaries/win32/jk-1.2.27/isapi_redirect-1.2.27.dll.
   
   Make sure you rename the file to isapi_redirect.dll before using it otherwise it will not work.
2. Place the isapi_redirect.dll file in a directory c:\ajp_iis (the name of the directory isn't important, but if you use a different one make sure to take account of this in the instructions which follow)
3. Create a isapi_redirect.properties file in the same directory as you put the DLL. You can use this sample isapi_redirect.properties file if you have used ajp_iis as the directory name.
   * Note that this sample properties file assumes that the dll is named isapi_redirect.dll. If you want to name your DLL something else, you must edit this file.
4. Create workers.properties and uriveworkermap.properties files. You can use the sample workers.properties file and the sample uriveworkermap.properties file.
5. Create an empty file named rewrites.properties in c:\ajp_iis.

Step 5. Connect Confluence with IIS

Connect Confluence with IIS, depending on your version of IIS:

- To connect Confluence with IIS 5.1 or 6 please refer to Connecting Confluence with IIS 5.1 or 6.
- For IIS 7 please refer to Connecting Confluence with IIS 7.

RELATED TOPICS

- Connecting Confluence with IIS 5.1 or 6
- Connecting Confluence with IIS 7
- JIRA's documentation on Configuring IIS with Tomcat, including how to integrate both Confluence and JIRA with the same IIS instance. The Troubleshooting section there is relevant to Confluence as well as JIRA.
- List Of Supported Application Servers

Connecting Confluence with IIS 5.1 or 6

This documentation is part of the Setting up Confluence with IIS documentation.

On this page:

- Connecting Confluence with IIS
- Other Configuration
- IIS 6.0
- Troubleshooting

Connecting Confluence with IIS

The configuration with IIS web-server is not supported by Atlassian support. The instructions below are for information only, and have been tested in this specific setup.

1. Using the IIS management console (Internet Information Services in Administrative Tools), add a new Virtual Directory to your IIS web site. The name of the virtual directory must be jakarta, as it must correspond with the first part of the extension_uri setting specified in the isapi_redirect.properties file. Its physical path should be the directory where you placed isapi_redirect.dll (in the example it is C:\ajp_iis). When creating this new virtual directory, give it execute access as well.
2. Using the IIS management console, add isapi_redirect.dll as a filter to your IIS web site. To do this, right click on the Web Sites icon from the left hand pane of the Internet Services Manager (or IIS management console), select Properties and then the ISAPI Filters tab. The name of the filter should reflect its task, for example confluence, and its executable must be the full path to the ajp isapi redirector DLL, that is c:\is\ajp\isapi_redirect.dll

3. Restart IIS (stop and start the IIS service -- do this by right-clicking on 'Local Computer' in the IIS Manager and choosing All Tasks, Restart IIS...). Ensure that the confluence filter is marked with a green up arrow verifying that it is loaded and initialized correctly. If the ajp redirector did not initialize properly, check the log file for errors messages (C:\ajp_iis\ajp_plugin.log).

You can now go to http://localhost and see the Confluence Dashboard.

Other Configuration

If you want to run Confluence on a named context, rather than the root context (i.e. access it via http://host/confluence/ instead of just http://host) you need to:

1. Change the path attribute of the Context tag in server.xml from "" to "confluence".
2. Change the line 
/*=ajp13w uriworkermap.properties to /confluence=*/ajp13w.
3. Note that http://host/confluence gives a 404 error, but http://host/confluence/ works. You need to create a virtual directory so that requests without the trailing slash still work. If you are using Confluence you would want to name the alias as confluence (if you are using JIRA, name it as jira). The physical directory can be anywhere and does not need to contain anything.

IIS 6.0

1. If using IIS 6.0 you will also need to add the Jakarta Isapi Redirector to the Web Service Extension's.
2. Right-click on Web Service Extensions and choose Add a new Web Service Extension...
3. Enter tomcat for the Extension Name and then add the isapi_redirect.dll file to the required files.
4. Check the Set extension status to Allowed and then click on OK.
5. Also add the Jakarta Isapi Redirector to the ISAPI Filters for the website

Troubleshooting

If you have problems, look in the System Event Log, the c:\iis_ajp\ajp_plugin.log and your confluence logs.

When requesting support for IIS configuration problems, please include:

1. A zip of your logs directory
2. A zip of your c:\iis_ajp directory
3. Your conf/server.xml file
5. A screen shot of the ISAPI Filters tab of the Properties window of your 'Web Sites' icon.

Connecting Confluence with IIS 7

This documentation is part of the Setting up Confluence with IIS documentation.

On this page:

- Setting up Confluence with IIS 7
- Known Issues
  - 64 bit IIS
  - Double Escaped Character
- Troubleshooting

Setting up Confluence with IIS 7

The configuration with IIS web-server is not supported by Atlassian support. The instructions below are for information only, and have been tested in this specific setup.

After you have installed IIS 7, you need to configure the Tomcat Connector. Then follow these steps:

1. Open IIS 7 Manager
2. Navigate to your host. In the picture below, your host would be the one highlighted in blue just below "Start Page".
3. Double click on the ISAPI and CGI Restrictions Icon
4. On the right hand panel, click on Add... Click here for picture
5. Point the path to your isapi_redirect.dll file and give it a description eg. tomcat. Give it an execute permission by clicking on
the Allow extension path to execute tick box.

6. Now, click on the Default Website and double click ISAPI Filter.

7. On the right hand panel, click on Add... and point to your isapi_redirect.dll file, give the filter a name (eg. tomcat)

8. Navigate to your Default Website again.

9. Right click on Default Website to create a virtual directory and name it jakarta, point this to your c:\ajp_iis directory.

10. Click on the newly created virtual directory jakarta and double click Handler Mappings.

11. Click on Edit Feature Permissions and tick the execute permission.

12. Add another virtual directory and name it confluence. Point the physical path to c:\confluence.

13. Set a context path in Confluence’s xml configuration. For example, if you are using Confluence Standalone distribution you need to edit <confluence install directory>/conf/server.xml and edit your context path to this:

```
<Context path="/confluence" docBase="../confluence" debug="0" reloadable="false"/>
```

The reason for creating this virtual directory is so that requests without the trailing slash still work. For example, if you are deploying Confluence under http://www.example.com/confluence/ without the virtual directory, then requests to http://www.example.com/confluence will fail.

14. Finally, navigate to your host context again and do a restart. Confluence should now be accessible via http://localhost/confluence

Known Issues

64 bit IIS

If you are running a 64 bit OS, please use a 64 bit version of the Tomcat IIS connector.

Customer submitted solution:
If you must use a 32 bit IIS connector, you can do so by clicking Application Pools > Advanced Settings > Allow 32bit applications.

Double Escaped Character

IIS 7 blocks double escaped character sequences by default. This will cause problems with Confluence pages with spaces. To fix this, please see http://support.microsoft.com/kb/942076.

Troubleshooting

The information in the Windows System Event Log can be useful for troubleshooting, followed by the c:\ajp_iis\ajp_plugin.log and your confluence logs.

When requesting support for IIS configuration problems, please include:

1. A zip of your logs directory
2. A zip of your c:\ajp_iis directory
3. Your conf/server.xml file

Take me back to Setting up Confluence with IIS

Setting Up Public Access
Granting of permissions to use Confluence can be done on the basis of membership of a group, to a particular user, or to the 'Anonymous' user. There is not an actual user named 'Anonymous', it is just a name for a category of granted permissions.

In the security administration of Confluence, the 'Anonymous' user includes all logged-in users, and anonymous users who have not logged in. That is, if you allow the 'Anonymous' user to do something, you are allowing all users to do it.

To enable public access to a confluence space, you must give 'Anonymous' the following permissions:

- The global 'Use Confluence' permission. This permission determines whether a user can access the Confluence installation at all, and is set by the site administrator in Administration -> Global Permissions.
- The relevant space permissions. The 'Anonymous' user must have at least the 'View Space' permission for a space to be publicly accessible. You set these permissions via 'Browse Space' -> 'Space Admin' -> 'Permissions'.

While these two permissions are the bare minimum necessary for public access to a space, you may wish to give 'Anonymous' additional permissions if you want a space to allow anonymous comments, or anonymous editing.

We severely warn against giving the 'Anonymous' user any administrative privileges, either within a space, or especially globally over the Confluence instance. Giving administrative privileges to untrusted users may lead to a serious security compromise of your site.

**Related**

- Enabling or Disabling Public Signup

**Setup a mail session in standalone version**

1. Add the following to your web.xml file (insert it just before </web-app>):

```xml
<resource-ref>
  <description>Test description</description>
  <res-ref-name>mail/Session</res-ref-name>
  <res-type>javax.mail.Session</res-type>
  <res-auth>Container</res-auth>
</resource-ref>
```

2. Add the following to your server.xml file (anywhere inside the <context ...> tags)

**For Tomcat 5.0.x**

```xml
<Resource name="mail/Session" auth="Container" type="javax.mail.Session"/>
<ResourceParams name="mail/Session">
  <parameter>
    <name>mail.smtp.host</name>
    <value>mail.example.com</value>
  </parameter>
  <parameter>
    <name>mail.smtp.port</name>
    <value>25</value>
  </parameter>
</ResourceParams>
```

**For Tomcat 5.5.x and Tomcat 6.x**

```xml
<Resource name="mail/Session" auth="Container" type="javax.mail.Session" mail.smtp.host="mail.example.com" mail.smtp.port="25" />
```

- To use the TLS protocol, add the property mail.smtp.starttls.enable="true" to this configuration.

You only need to specify the mail.smtp.port parameter if you are using a non-standard port for SMTP.

3. Restart the server. Go to create SMTP mail server screen. For JNDI location, enter:

```java
java:comp/env/mail/Session
```

**Start Confluence automatically on system startup**

Confluence can be configured to start automatically on system startup, allowing it to recover automatically after a reboot.
Start Confluence automatically on Linux & Unix

On Unix/Linux, the best practice is to install, configure and run each service (including Confluence) as a dedicated user with only the permissions they require.

To install, configure and run Confluence automatically on Unix/Linux:

1. Create a `confluence` user for instance, using the following command:

   ```sh
   sudo useradd --create-home -c "Confluence role account" confluence
   ```

2. Create a directory to install Confluence into:

   ```sh
   sudo mkdir /usr/local/confluence
   sudo chown confluence: /usr/local/confluence
   ```

3. Log in as the `confluence` user to install Confluence:

   ```sh
   sudo su - confluence
cd /usr/local/confluence/
tar zxvf /tmp/confluence-3.0.1-std.tar.gz
   ln -s confluence-3.0.1-std/ current
   # Edit current/confluence/WEB-INF/classes/confluence-init.properties, and set
   # confluence.home=/usr/local/confluence/home
   ```

4. Then back as root, create the file `/etc/init.d/confluence` (code shown below), which will be responsible for starting up Confluence after a reboot (or when manually invoked).

   ```sh
   #!/bin/sh
   # confluence-service
   #
   # $Id$
   #
   # This script starts up the Confluence server.
   # It will start the server after a reboot or manual invocation.
   #
   # Usage:
   # confluence-service start
   # confluence-service stop
   # confluence-service status
   # confluence-service restart
   #
   # $Author$ 
   # $Date$ 
   # $Revision$ 
   #
   # Copyright 2004-2005 Atlassian
   if [ -x /usr/bin/java ]; then
     java -jar /usr/local/confluence/current/confluence.jar
   else
     java /usr/local/confluence/current/confluence.jar
   fi
   ```

   **Note:** If you are running Ubuntu Jaunty (or later) do not perform this step. Please use the instructions further down this page.
5. Make this file executable:

```
sudo chmod +x /etc/init.d/confluence
```

6. Set this file to run at the appropriate runlevel. For example, use `sudo ntsysv` on Redhat-based systems, `sudo update-rc.d confluence defaults` or `rcconf` on Debian-based systems.

7. You should now be able to start Confluence with the init script. A successful startup output typically looks like this:

```
$ sudo /etc/init.d/confluence start
Starting Confluence:
If you encounter issues starting up Confluence Standalone, please see the Installation guide at http://confluence.atlassian.com/display/DOC/Confluence+Installation+Guide
Using CATALINA_BASE: /usr/local/confluence/current
Using CATALINA_HOME: /usr/local/confluence/current
Using CATALINA_TMPDIR: /usr/local/confluence/current/temp
Using JRE_HOME: /usr/lib/jvm/java-1.5.0-sun
done.
```

ℹ️ You should then see this running at `http://<server>:8080/`. 
Adding Confluence as a service for Ubuntu Jaunty (or later)

To continue configuring Confluence to start automatically as a service on Ubuntu Jaunty (or later):

1. After logging in as the confluence user to install Confluence, create start and stop scripts in /usr/local/confluence:

   Example start script:

   ```bash
   #!/bin/bash
   export JAVA_HOME=/usr/lib/jvm/java-6-sun-1.6.0.16/
   export JDK_HOME=/usr/lib/jvm/java-6-sun-1.6.0.16/
   cd /usr/local/confluence/current/bin
   ./startup.sh
   ```

   Example stop script:

   ```bash
   #!/bin/bash
   export JAVA_HOME=/usr/lib/jvm/java-6-sun-1.6.0.16/
   export JDK_HOME=/usr/lib/jvm/java-6-sun-1.6.0.16/
   cd /usr/local/confluence/current/bin
   ./shutdown.sh
   ```

2. Make both of these scripts executable. For example, by issuing the command: `sudo chmod a+x /usr/local/confluence/start /usr/local/confluence/stop`.

3. Create two text files in /etc/event.d/ called confluence-up and confluence-down:

   confluence-up:

   ```bash
   start on runlevel 2
   start on runlevel 3
   start on runlevel 4
   start on runlevel 5
   ```

   ```bash
   exec sudo -u confluence /usr/local/confluence/start >> /tmp/confluence-startup.out 2>&1
   ```

   confluence-down:

   ```bash
   start on runlevel 1
   start on runlevel 6
   ```

   ```bash
   exec sudo -u confluence /usr/local/confluence/stop >> /tmp/confluence-shutdown.out 2>&1
   ```

RELATED TOPICS

Start Confluence automatically on system startup

Start Confluence automatically on OS X using launchd

`launchd` is the OS X component which manages long running processes - daemons or services.

Apple has an introduction to `launchd`.

There's a mismatch between how launchd expects a daemon to behave, and how the default startup scripts for Tomcat (the application server used by the stand-alone Confluence distribution) operate. Launchd expects the process it starts to run forever, but 'catalina.sh start' starts the JVM to run Tomcat and then exits. Tomcat provides 'catalina.sh stop' to cleanly shut down Tomcat by connecting to a socket which Tomcat listens on, but launchd stops daemons by sending them a signal, which simply kills the process immediately if no specific handling is included.

To match Tomcat to launchd, we need to write a wrapper shell script, which we add to $CATALINA_HOME/bin:
This shell script starts Tomcat, and then waits for the process to complete, so launchd is happy that Tomcat is still running. It also installs a signal handler, which calls the shutdown() function to cleanly shut down Tomcat when launchd signals the script.

You can try this script manually - start it, watch Confluence start, and then type `ctrl-C`, and see Confluence shut down cleanly (note that it won't shut down cleanly if Tomcat hasn't started yet - it takes a few seconds for Tomcat to start listening on the shutdown socket).

We also need a launchd .plist, to tell launchd how to start Tomcat:

```xml
<plist version="1.0">
  <dict>
    <key>Disabled</key>
    <false/>
    <key>EnvironmentVariables</key>
    <dict>
      <key>CATALINA_HOME</key>
      <string>/Users/tomd/conf/confluence-2.1.3-std</string>
      <key>JAVA_HOME</key>
      <string>/Library/Java/Home</string>
    </dict>
    <key>Label</key>
    <string>com.atlassian.confluence</string>
    <key>OnDemand</key>
    <false/>
    <key>ProgramArguments</key>
    <array>
      <string>/Users/tomd/conf/confluence-2.1.3-std/bin/launchd_wrapper.sh</string>
    </array>
    <key>RunAtLoad</key>
    <true/>
    <key>ServiceDescription</key>
    <string>Confluence</string>
    <key>StandardErrorPath</key>
    <string>/Users/tomd/conf/confluence-2.1.3-std/logs/launchd.stderr</string>
    <key>StandardOutPath</key>
    <string>/Users/tomd/conf/confluence-2.1.3-std/logs/launchd.stdout</string>
    <key>UserName</key>
    <string>tomd</string>
  </dict>
</plist>
```

This file needs to be placed in /Library/LaunchDaemons, which is the location for system-wide services which are not part of base OS X.

There are a number of things to note about this plist:

1. The path to your Confluence installation has to be explicitly specified in four places. I don't know if there's a better solution to this.
2. JAVA_HOME is set to use the default JDK. On 10.4.4 this is 1.4.2, if you want to use 1.5 you would need to change JAVA_HOME to
To start and stop Confluence manually you use the commands:
```
cd /Library/LaunchDaemons
sudo launchctl load -w confluence.plist
and
sudo launchctl unload -w confluence.plist
```

I confess that I don’t understand the semantics of `launchctl start/stop` - stopping a daemon seems to kill the process, but then `launchd` immediately restarts it.

**Related Topics**

Start Confluence automatically on system startup

**Start Confluence automatically on Windows as a Service**

For long-term use, we recommend that you configure Confluence to start automatically when the operating system restarts. For Windows servers, this means configuring Confluence to run as a Windows service.

**Note for 64-bit Windows**

If you are running 64-bit Windows, please note that Apache Tomcat cannot run as a Windows service if you are using a 64-bit JDK. Please ensure that you are using a 32-bit JDK. (If you used the automated Confluence Installer, you will not run into this problem because a 32-bit JDK has already been installed for you.) For more information, please refer to CONF-12293 for a workaround if you intend to continue using the 64-bit JDK.

There are two ways to install Confluence Standalone as a service: via the Confluence installer or manually as described below.

**On this page:**

- Reasons for Starting Confluence as a Service
- Using the Installer to Install Confluence as a Service
- Manually Installing Confluence Standalone as a Service
- Managing Confluence as a Service
- Upgrading Confluence
- Troubleshooting Confluence while Running as a Windows Service
- Check the Knowledge Base Articles
- Requesting Support

**Reasons for Starting Confluence as a Service**

Installation as a Windows service offers these advantages:

- Reduced risk of shutting down Confluence by accident. (If you start Confluence manually, a console window opens and there is a risk of someone accidentally shutting down Confluence by closing the window.)
- Automated Confluence recovery after server restart
- Improved troubleshooting through logging server output to file

You can read more about Windows services in the Microsoft Developer Network.

**Using the Installer to Install Confluence as a Service**

If you use the automated Confluence Installer to install Confluence on Windows, you will be prompted to choose to install Confluence as a Windows service. For more information about the automated Confluence Installer, please refer to Installing Confluence Standalone Using the Automatic Installer.

**Manually Installing Confluence Standalone as a Service**

From your Windows-based server:

1. Open a command prompt in the `<CONFLUENCE-INSTALL>/bin` directory.

   ```
   echo %JAVA_HOME%
   ```

   Note that any directory in the path with spaces (e.g. `C:\Program Files` must be converted to its eight-character equivalent (e.g. `C:\Progra~1`).

2. Confirm that the `JAVA_HOME` variable is set to the JDK base directory with the command:

3. If you are installing Confluence on a Windows 2008 server, be sure to run the command prompt using 'run as administrator'.
4. Use the following command to install the service with default settings:

```
service.bat install Confluence
```

5. Now, to have the service start automatically when the server starts, run:

```
tomcat6 //US//Confluence --Startup auto
```

6. If you have a less than a 512 megabytes of memory, skip this step. For users with large Confluence installations, you can increase the maximum memory Confluence can use. (The default is 256MB). For example, you can set the maximum memory to 512 megabytes using:

```
tomcat6 //US//Confluence --JvmX 512
```

7. If you do not have any JVM parameters you pass to your standalone distribution of Confluence, you can skip this step. If you do, add them to the service using:

```
tomcat6 //US//Confluence ++JvmOptions="-Djust.an.example=True"
```

8. For further configuration options, please refer to the Tomcat Windows Service How-To guide

9. Go to your Windows Control Panel -> Administrative Tools -> Services -> Apache Tomcat Confluence and right-click on Properties to verify the settings are correct.

10. If you wish to run the service as a non-administrator user for security, or if you are using network drives for backups, attachments or indexes, you can run the service as another user. To change users, open the Apache Tomcat Confluence properties, go to the 'Log On' tab and enter the required username and password. Go to your Windows Control Panel -> User Accounts and confirm that the user has write permissions for the %CATALINA_HOME%, index and database directories. Note that any network drives must be specified by UNC and not letter mappings (e.g. \\backupserver\confluence not z:\confluence

   Confluence is now be installed as a service, but will not automatically start up until the next server reboot

11. Start the Confluence service with the command:

```
net start Confluence
```

Managing Confluence as a Service

You can manage the Confluence service from the command prompt.

- Stop Confluence with:

```
net stop Confluence
```

- Uninstall the Confluence service with:

```
service.bat remove Confluence
```

Upgrading Confluence

After upgrading Confluence, you can either uninstall and reinstall the Windows service or change the StartPath parameter to your new folder. Refer to the Tomcat documentation for help.

Troubleshooting Confluence while Running as a Windows Service

- When investigating memory issues or bugs, it may be useful to view information from Confluence’s garbage collection. To turn on the verbose garbage collection, use the command:

```
tomcat6 //US//Confluence ++JvmOptions="-Xloggc:<CONFLUENCE-INSTALL>/logs\atlassian-gc.log"
```

If you are running 64-bit Windows, please note that Apache Tomcat cannot run as a Windows service if you are using a 64-bit JDK. Please ensure that you are using a 32-bit JDK. (If you used the automated Confluence Installer, you will not run into this problem because a 32-bit
JDK has already been installed for you.) For more information, please refer to [CONF-12293](http://jira.atlassian.com/browse/CONF-12293) for a workaround if you intend to continue using the 64-bit JDK.

Starting the service produces an error similar to `Failed creating java C:\jdk1.6.0_10\jre\bin\server\jvm.dll`. This is because Tomcat is looking for a `msvcr71.dll` file. Please refer to this [Knowledge Base article](http://jira.atlassian.com/browse/CONF-12293).

Unable to start Confluence as service after Allocating higher JVM Memory. Please refer to this [Knowledge Base article](http://jira.atlassian.com/browse/CONF-12293).

Confluence 2.9 Installer does not work when installed as service, due to missing semi-colon in `service.bat`. Please refer to reported issue [CONF-12785](http://jira.atlassian.com/browse/CONF-12785).

You can use a [Sysinternals tool](http://www.sysinternals.com) called `Procmon.exe` from the The Microsoft Windows Sysinternals Team, to check the error occurred at the specific time when starting Confluence Service. You need to match the time when Tomcat failed captured by this tool against the time in Windows’ Event Viewer.

Note that it is not recommended that you run this tool too long as it may disrupt other Atlassian applications. So once you have captured the required information you will need to press Ctrl + E to stop capturing.

Check the Knowledge Base Articles

**Supported Platforms FAQ**

**Q: How does Atlassian choose which JDK versions, application servers and databases to support?**

For databases and application servers, we try to pick a good cross-section, including open source options and the popular commercial platforms. We then choose which JDK versions to support based on the recommended environments for these servers.

**Q: What does it mean that a platform is supported?**

- Confluence is regularly tested on that platform during the development cycle.
- The platform is available within Atlassian for support technicians and developers to reproduce problems
- Bugs specific to that platform will be given a high priority

Supporting a platform means we know how to get Confluence running in that environment, and can troubleshoot Confluence issues within it. It does not mean we have any particular expertise beyond that. As such, we may not be able to help with customising or tuning that application server or database. Atlassian support is not a substitute for a good DBA.

**Q: What does it mean that a platform is not supported?**

If you are running Confluence on an unsupported platform, there is a limit to the level of support we can provide. We will support your application, but if we run into problems, we will recommend switching to a supported platform:

- Confluence has not been tested on that platform by Atlassian
- Developers and support technicians will be unable to reproduce problems on that platform
- Bugs specific to that platform will be given a low priority

If you are technically minded, enjoy a challenge and (most importantly) are able to switch platforms if things don't work out, we encourage you to try new things. Please report back on your experiences. Keep in mind that even just by repackaging Tomcat, vendors can horribly break things (e.g. JBoss 3's classloader), and that problems often arise in infrequently used parts of JIRA (upgrades, bulk operations, plugins, concurrent operations).

If you just want something to work, we recommend sticking to what we know works. There are plenty of free, high quality app servers and databases available, and few reasons not to use them.

**Q: If you write your application to standards like J2EE, JDBC and SQL, doesn't that mean it should run on any compliant server?**

The operative word there is *should*. Confluence is a complicated application, and we commonly come across interesting edge-cases, places where servers have interpreted the specifications differently, and straight-out incompatibilities. Then, of course, each server has its own
Q: How can I get Atlassian to support Confluence on a new platform?

Supporting a new platform involves a significant investment of time by Atlassian, both up-front costs to set up new testing environments and fix any issues we might encounter, and the ongoing costs involved in maintaining the application against this new environment in the future. As such, supporting a new platform is not something we will do unless we know there is significant demand.

So let us know you're interested. File an issue in JIRA (or vote on an existing issue). Start a thread in the user forum. Just keep in mind that your interest alone will not be enough to convince us to add support for your application server or database: we'd need to see a number of votes on the issue, or a significant level of interest in the forum thread.

Q: My organisation has standardised on an operating environment that Confluence does not support. What can I do?

Ultimately, you really only have two options:

1. Run Confluence in the unsupported environment, with all the caveats mentioned above
2. Make an exception to your standard environment

By all means let us know that your preferred environment is not supported. However, even if we did decide to add support it would be unlikely that we'd be able to do so in any timeframe that would suit your deployment of Confluence in the short term.

List Of Supported Operating Systems

- **Confluence on Virtualised Environments**
  We are proud to announce that Atlassian officially supports non-clustered installations of Confluence 3.0 and later on VMware. Although possible, we do not recommend running versions of Confluence prior to 3.0 on VMware, since Confluence 3.0 resolved many performance issues that were present in earlier versions. Be aware that we do not support clustered installations of Confluence on VMware. For more information, please refer to Running Confluence in a Virtualised Environment.

- While some of our customers run Confluence on SPARC-based hardware, Atlassian only officially supports Confluence running on x86 hardware and 64-bit derivatives of x86 hardware.

Supported operating systems:

- Windows (including 64-bit)
- Linux
- Mac OS X
- Solaris
- Unix

Confluence should work on any system that has Java 5 support. If you can get Confluence running on an unsupported operating system we will still try to help you if you encounter problems, but we may ask you to move to a supported operating system before we can provide more detailed support.

  - Spaces
- Appearance
- Miscellaneous
The Hibernate mapping files are the authoritative reference. These are the *.hbm.xml files which have been bundled into the main Confluence .jar file in recent releases.

This document is little more than the Confluence schema with added comments, but the priority was placed on making the information available.

General Database Diagram

Authentication

Atlassian-user

This is the "new" authentication system, which is more flexible and extensible than OpenSymphony.

Table "groups"

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Modifiers</th>

---

**Troubleshooting SQL Exceptions**

If you get an exception similar to those shown below, it is a good idea to increase the logging levels of your Confluence instance. If you request Atlassian support, this additional logging will help us work out the cause of the error.

Increased logging levels will enable us to diagnose errors like these:
This document outlines the steps to take to increase logging on your system.

### Changing the logging levels via the Administration Console

With Confluence 2.7 and later, you can adjust logging levels at runtime via the Administration Console — read the instructions. Below we tell you how to edit the log4j files directly.

1. Open `confluence/WEB-INF/classes/log4j.properties` and uncomment the following lines. The double `##` lines are comments, leave them intact.

   ```
   ## log hibernate prepared statements/SQL queries (equivalent to setting 'hibernate.show_sql' to 'true')
   #log4j.logger.net.sf.hibernate.SQL=DEBUG, confluencelog
   #log4j.additivity.net.sf.hibernate.SQL=false
   ## log hibernate prepared statement parameter values
   #log4j.logger.net.sf.hibernate.type=DEBUG, confluencelog
   #log4j.additivity.net.sf.hibernate.type=false
   ```

   If you can not locate these lines in your `log4j.properties` file, please add them to the end of it.

2. Restart Confluence.
3. Redo the steps that led to the error.
4. Zip up your logs directory and attach it your support ticket.
5. If you are using Oracle and received a constraint error, please ask your database administrator which table and column the constraint (that is, `CONFLUENCE.SYS_C0012345`) refers to and add that information to your support ticket.

### Upgrading Confluence

This guide will tell you how to upgrade from one version of Confluence to a later version. Choose the type of installation you are upgrading, and follow the link to the installation instructions.

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standalone distribution</td>
<td>The Standalone distribution is the simplest installation, using an Apache Tomcat application server bundled with the Confluence application. Choose this option if your existing Confluence installation is a Standalone deployment.</td>
</tr>
<tr>
<td></td>
<td><img src="image" alt="If in doubt, this is the one you want." /></td>
</tr>
<tr>
<td>EAR/WAR distribution</td>
<td>Use this guide if you have deployed Confluence onto your own existing application server.</td>
</tr>
</tbody>
</table>
Upgrading to Confluence 3.0.2?

If so, please review the Confluence 3.0.2 Upgrade Notes for important information about this version of Confluence.

Also, it is strongly recommended that you check the upgrade notes for every major version of Confluence that you are skipping, since there might be specific changes between Confluence versions that could affect your Confluence installation. The upgrade notes pages for recent major versions of Confluence are accessible from the Upgrade Notes Overview page.

Confluence Installation Guide

Upgrading Confluence Standalone Distribution

This document tells you how to upgrade from one version of Confluence to a later version.

These instructions apply to:

- The Standalone Distribution of Confluence. The Standalone distribution includes Apache Tomcat as the standalone application server. If you want to upgrade an EAR/WAR distribution deployed on your own existing application server, please refer to Upgrading Confluence EAR-WAR Distribution.

Also, please check the new version of Confluence which you are installing. Refer to the documentation home page to verify the latest Confluence version and to find documentation for older versions.

On this page:

- Before you Start
- Backing Up
- Testing the Upgrade in a Test Environment
- Performing the Upgrade
- Reapplying Customisations to your New Confluence
- Troubleshooting the Confluence Upgrade

Upgrading a Cluster or Changing your Database?

- If you are running Confluence on a cluster, please see Upgrading a Confluence Cluster instead of this document.
- If you are planning to change to a different database, we recommend that you complete the Confluence upgrade first. Then follow the instructions on migrating to a different database.

Before you Start

1. Note that you need current software maintenance to perform the upgrade.
2. Confirm that your license support period is still valid before you try to upgrade.
3. If your current license has expired but you have a new license with you, please update your license in Confluence before performing the upgrade.
   
   If you forget to do this and your license has expired, you will receive errors during the upgrade process. Refer to the instructions on upgrading beyond current license period.
4. Check the release notes for the new version of Confluence you are installing, plus the upgrade notes for any major versions you are skipping. It is important to read these upgrade notes as there might be specific changes between Confluence versions that could affect your Confluence instance. The upgrade notes pages for recent major versions of Confluence are accessible from the Upgrade Notes Overview page. (Each upgrade notes page is a ‘child’ of its respective release notes page.)
   
   If you are upgrading from a version of Confluence prior to 2.5.5, the upgrade notes information is located under a heading on the release notes pages.
5. Make sure that your environment (e.g. the database system, the operating system, the application server and so on) still complies with the Confluence System Requirements. A newer version of Confluence may have different requirements than the previous version.
Before you begin the Confluence upgrade, you must back up the following:

1. **Back up your Confluence Home directory.**
   - The Confluence Home directory is the folder where Confluence stores its configuration information, search indexes and page attachments. If you're using the embedded HSQLDB database supplied for evaluation purposes, the database files are also stored in this directory.
   - Tip: Another term for 'Home directory' would be 'data directory'.
   - The location of the Home directory is stored in a configuration file called `confluence-init.properties`, which is located inside the `conf/Web-INF/classes` directory in your Confluence Installation directory.

2. **Back up your database.**
   - Perform a manual backup of your external database before proceeding with the upgrade, and double check that the backup was actually created properly. If you are not familiar with the backup-restore facilities of your database, you should try to restore the backup to a different system to ensure the backup worked, before proceeding. This recommendation is not specific to Confluence usage but just common sense: Surprisingly many companies, even banks, get in trouble for broken database backups.
   - The 'embedded database' is the HSQLDB database supplied with Confluence for evaluation purposes, you don't need to back it up since it is stored in the home directory. But you should not use this database for production systems anyway, so if you happen to accidentally still use HSQLDB in a production system, please migrate to a proper database before the upgrade.

3. **Back up your Confluence Installation directory** (if you are using Confluence Standalone) or your **Confluence webapp** (if you are using Confluence EAR-WAR edition).
   - The 'Confluence Installation directory' is the directory into which the Confluence application files and libraries have been unpacked (unzipped) when Confluence was installed. Confluence does not modify or store any data in this directory. This directory is also sometimes called the 'Confluence Install directory'.

### Testing the Upgrade in a Test Environment

**Be sure to test the upgrade in a test environment before proceeding on your production server.**

1. Create a snapshot of your current production Confluence environment on a test server, as described in the page on Moving Confluence Between Servers.
2. Perform the upgrade on your cloned environment.
3. Test all your unsupported plugins and any customisations with the new version before proceeding on your production server. You can read more about supported and unsupported plugins.

### Performing the Upgrade

**There is a common misconception** about upgrades: people seem to think that you have to export your attachments and database to a new location and start Confluence using those copies. **That is not the case!** While you need to make backups and ensure the backups work, the upgrade itself should be done using the **same** home-directory and database location. Read about the details here:

To install Confluence, unzip the new Confluence installation zip file into a directory of your choice and then edit the configuration files to point your new installation to your existing data files. Follow these instructions:

1. Shut down your existing Confluence instance.
2. Download the Confluence Standalone zip file.
3. **If you are on Windows**, please check your unzip program before extracting the downloaded zip file. Some archive-extract programs cause errors when unzipping the Confluence zip file. You should use a third-party unzip program like 7Zip or Winzip. If you do not have one, please download and install one before continuing:
   - 7Zip — Recommended. If in doubt, download the '32-bit.exe' version
   - Winzip
4. Use your unzip program to unzip the installation file. You should now have a new directory called `confluence-<version>`, e.g. `confluence-2.9.2-std`.
   - In the rest of this document, we will refer to this as the `<Installation-Directory>`.
   - If you decide to change the location from the default, make sure that you choose a different location from your existing Confluence installation, because legacy files may cause problems if you install the new Confluence version into an existing directory.
- Do not use spaces in your directory path.
- You can read more about the Confluence Installation directory.

5. Edit the `confluence-init.properties` file found at:
   `<Installation-Directory>/confluence/WEB-INF/classes/confluence-init.properties` and update `confluence.home` to point to your existing Confluence Home directory.
- You can read more about the Confluence Home directory.
- Make sure you have first backed up this directory, as instructed above.
- Open the `confluence-init.properties` file in a text editor such as Notepad.
- Scroll to the bottom and find this line:

   ```
   # confluence.home=c:/confluence/data
   ```

- Remove the `#` and the space at the beginning of this line, so that Confluence no longer regards the line as a comment. The line should now begin with `confluence.home`.
- Update the directory name after the `=` sign, to point to your existing Confluence Home directory.

6. If you are running Confluence as a Windows service, use `<Installation-Directory>/bin\tomcat5w.exe` to remove and reinstall the Tomcat service. Or use the command prompt and type `<Installation-Directory>/bin\service.bat remove Confluence`.

   It is vital that you stop and remove the existing service prior to uninstalling the old instance of Confluence! For more information on running Confluence as Windows service, please refer to the Start Confluence automatically on Windows as a Service topic.

   To remove the service installed by Confluence Auto Installer, you need to run the `<confluence auto installer installation folder>\UninstallService.bat`.

7. If you are using an external database (i.e. not the embedded HSQLDB database supplied for evaluation purposes), copy the `jdbc` driver jar file from your old Confluence Standalone installation to the new Confluence Standalone installation. The `jdbc` driver jar file in the old Confluence Standalone installation should be located in either the `<Install-Directory>/common/lib` or `<Installation-Directory>/confluence/WEB-INF/lib` directories. Once you have identified this file, copy it to either the `<Install-Directory>/lib` or `<Installation-Directory>/confluence/WEB-INF/lib` directories of your Confluence 3.x installation.

8. If you have delegated your user management to JIRA, LDAP, Crowd, or any other external user management system, copy the following files from your old Confluence installation to your new Confluence installation:
   - `<Installation-Directory>/confluence/WEB-INF/classes/osuser.xml`.
   - `<Installation-Directory>/confluence/WEB-INF/classes/atlassian-user.xml` (if you are upgrading from Confluence 2.2 or later).

   If you are upgrading from an earlier version of Confluence (2.5.5 and earlier) and are copying your existing `atlassian-user.xml` file from your previous instance, please ensure that the hibernate cache parameter in this file has been enabled, to avoid performance related issues. (NOTE: If you use Crowd for your user management, you do not need to do this.):

   ```
   <hibernate name="Hibernate Repository" key="hibernateRepository" description="Hibernate Repository" cache="true" />
   ```

9. If you have delegated your user management to Crowd, you will also need to copy the Crowd Client library and configuration files from your old Confluence installation to your new Confluence installation:
   - `<Installation-Directory>/confluence/WEB-INF/lib/crowd-integration-client-X.X.X.jar` and
   - `<Installation-Directory>/confluence/WEB-INF/classes/crowd.properties`

   If you need more information, please refer to the Crowd documentation.

10. Consider any adjustments you need to make to customisations and special configurations, as described below.

    Your new version of Confluence may not function correctly or could encounter problems or errors if these are not implemented.

11. Start your new version of Confluence.

    Please note that Confluence will need to re-index attachments and this can take 5-10 minutes. Please wait until Confluence has finished indexing the attachments before trying to access Confluence via your web browser.

12. During the startup process Confluence will create any missing database indexes. If you created any database indexes on your own, please check those afterwards and remove those that duplicate the indexes added by Confluence. Just in case you run into any errors which prevent Confluence from starting up, you can set the system property `hibernate.hbm2ddl.skip_creating_missing_indexes true` to skip automatic index creation.

13. Visit Confluence in your web browser and log in using a username from your previous Confluence installation. You should be able to log in immediately, without seeing the Setup Wizard.

14. Take a quick look around your Confluence site to confirm that all your spaces and pages are present and everything looks normal. You should see the new Confluence version number in the page footer.

**Reapplying Customisations to your New Confluence**
After upgrading your Confluence installation to a later version of Confluence, you need to consider any customisations you have applied to your system and other special configurations:

- If you had previously installed Confluence/Tomcat as a Windows service, uninstall the service (to ensure that the old Confluence cannot start automatically when the server restarts) and reinstall the new one. For details please see Start Confluence automatically on Windows as a Service.
- If you are using a Standalone Edition of Confluence and you have previously defined a CATALINA_HOME environment variable, please check that it points to the correct path for the new Confluence Tomcat server.
- If you had previously connected your Confluence installation to an external database via a JNDI datasource or you implemented SSL, edit your new web.xml file and and copy over any relevant modifications from your old web.xml file, which relate to these customisations.
- If you were previously running Confluence on a non-standard port, edit your new <Installation-Directory>/conf/server.xml file as described in Change listen port for Confluence Standalone.
- If you had previously defined a Tomcat datasource, edit your new <Installation-Directory>/conf/server.xml and copy over the datasource definition from your old server.xml.
- If you were previously using any plugins, install the latest compatible version and disable any plugins that are incompatible with your new version of Confluence. The easiest way to do this is to use the Plugin Repository in the Confluence Administration Console.
- If you are using any customised themes, please check that they are displaying as expected. Some further customisation may be required to ensure compatibility with your new version of Confluence.
- If you had previously customised the default site or space layouts, you will need to reapply your changes to the new defaults as described here.
- If you had previously modified the Confluence source code, you will need to reapply your changes to the new version.
- If you were previously running Confluence over SSL, you will need to reapply your configuration as described in Adding SSL for Secure Logins and Page Security.
- If you had previously modified the memory flags (Xms and Xmx) in either the <Installation-Directory>/bin/setenv.sh or the <Installation-Directory>/bin/setenv.bat file, you may want to make the modifications in your new installation. The parameters are specified in the JAVA_OPTS variable.
- If you had changed the Confluence interface text, you will need to pull over the ConfluenceActionSupport.properties file.
- If you were using a custom SSO authenticator or the utility to Automatically Add LDAP users to the confluence-users Group, change seraph-config.xml to the correct authenticator.

Troubleshooting the Confluence Upgrade

Refer to Troubleshooting Upgrades from the Confluence Knowledge Base.

Upgrading Confluence EAR-WAR Distribution

This document tells you how to upgrade from one version of Confluence to a later version.

These instructions apply to:

- The EAR-WAR Distribution of Confluence, deployed on your own existing application server. If you want to upgrade your Confluence Standalone distribution, which includes Apache Tomcat as the standalone application server, please refer to Upgrading Confluence Standalone Distribution.

Also, please check the new version of Confluence which you are installing. Refer to the documentation home page to verify the latest Confluence version and to find documentation for older versions.
Upgrading to Confluence 3.0.2?

If so, please review the Confluence 3.0.2 Upgrade Notes for important information about this version of Confluence.

Also, it is strongly recommended that you check the upgrade notes for every major version of Confluence that you are skipping, since there might be specific changes between Confluence versions that could affect your Confluence installation. The upgrade notes pages for recent major versions of Confluence are accessible from the Upgrade Notes Overview page.

On this page:
- Before you Start
- Backing Up
- Testing the Upgrade in a Test Environment
- Performing the Upgrade
- Reapplying Customisations to your New Confluence
- Troubleshooting the Confluence Upgrade

Upgrading a Cluster or Changing your Database?

- If you are running Confluence on a cluster, please see Upgrading a Confluence Cluster instead of this document.
- If you are planning to change to a different database, we recommend that you complete the Confluence upgrade first. Then follow the instructions on migrating to a different database.

Before you Start

1. Note that you need current software maintenance to perform the upgrade.
2. Confirm that your license support period is still valid before you try to upgrade.
3. If your current license has expired but you have a new license with you, please update your license in Confluence before performing the upgrade.
   - If you forget to do this and your license has expired, you will receive errors during the upgrade process. Refer to the instructions on upgrading beyond current license period.
4. Check the release notes for the new version of Confluence you are installing, plus the upgrade notes for any major versions you are skipping. It is important to read these upgrade notes as there might be specific changes between Confluence versions that could affect your Confluence instance. The upgrade notes pages for recent major versions of Confluence are accessible from the Upgrade Notes Overview page. (Each upgrade notes page is a 'child' of its respective release notes page.)
   - If you are upgrading from a version of Confluence prior to 2.5.5, the upgrade notes information is located under a heading on the release notes pages.
5. Make sure that your environment (e.g. the database system, the operating system, the application server and so on) still complies with the Confluence System Requirements. A newer version of Confluence may have different requirements than the previous version.
6. If you are using Confluence EAR-WAR edition, check Installing the Confluence EAR-WAR Edition for your specific application server, to see if there is anything extra you will need to do to get Confluence running. For example:
   - If you are using Confluence EAR-WAR edition, check Installing the Confluence EAR-WAR Edition for your specific application server, to see if there is anything extra you will need to do to get Confluence running.
7. If you are using an external database, familiarize yourself with all known issues for your specific database. Also make sure the Confluence database connector principal (the database user login) has sufficient permissions to modify the database schema.
8. Note which plugins are installed/enabled on your current Confluence instance. Please verify whether a compatible version of the plugin is available in the version of Confluence you are upgrading to. This information is available on the respective home pages for these plugins on the Confluence Extension space. Once you have confirmed the availability of compatible versions, you should upgrade your plugins after successfully upgrading Confluence. This can be done via the Plugin Repository Administration Console. Please test these first by applying them to the latest Confluence version in a test environment.
9. If you have made any customisations to Confluence, please verify their compatibility in the latest version. For example, if you have modified any layouts or are using your own custom theme, please test these first by applying them to the latest Confluence version in a test environment.

Backing Up

Before you begin the Confluence upgrade, you must back up the following:

1. **Back up your Confluence Home directory.**
   - The Confluence Home directory is the folder where Confluence stores its configuration information, search indexes and page attachments. If you're using the embedded HSQLDB database supplied for evaluation purposes, the database files are also stored in this directory.
   - Tip: Another term for 'Home directory' would be 'data directory'.
   - The location of the Home directory is stored in a configuration file called confluence-init.properties, which is located inside the confluence/WEB-INF/classes directory in your Confluence Installation directory.
2. **Back up your database.** Perform a manual backup of your external database before proceeding with the upgrade, and double check that the backup was actually created properly. If you are not a database expert, or unfamiliar with the backup-restore facilities of your database, you should try to restore the backup to a different system to ensure the backup worked, before proceeding. This recommendation is not specific to Confluence usage but just common sense: Surprisingly many companies, even banks, get in trouble for broken database backups.
The 'embedded database' is the HSQLDB database supplied with Confluence for evaluation purposes, you don't need to back it up since it is stored in the home directory. But you should not use this database for production systems anyway, so if you happen to accidentally still use HSQLDB in a production system, please migrate to a proper database before the upgrade.

3. **Back up your Confluence Installation directory** (if you are using Confluence Standalone) or **your Confluence webapp** (if you are using Confluence EAR-WAR edition).
   The 'Confluence Installation directory' is the directory into which the Confluence application files and libraries have been unpacked (unzipped) when Confluence was installed. Confluence does not modify or store any data in this directory. This directory is also sometimes called the 'Confluence Install directory'.

### Testing the Upgrade in a Test Environment

1. Create a snapshot of your current production Confluence environment on a test server, as described in the page on Moving Confluence Between Servers.
2. Perform the upgrade on your cloned environment.
3. Test all your unsupported plugins and any customisations with the new version before proceeding on your production server. You can read more about supported and unsupported plugins.

### Performing the Upgrade

The upgrade process allows you to unzip the new Confluence installation into a directory of your choice and then edit the configuration files to point your new installation to your existing data files. Follow these instructions:

1. Shut down your existing Confluence instance.
2. Download the Confluence EAR-WAR zip file: Go to the [Download Centre](https://confluence.org) and click 'Show all' to find the EAR-WAR zip file.
3. If you are on Windows, please check your unzip program before extracting the downloaded zip file. Some archive-extract programs cause errors when unzipping the Confluence zip file. You should use a third-party unzip program like 7Zip or Winzip. If you do not have one, please download and install one before continuing:
   - 7Zip — Recommended. If in doubt, download the '32-bit.exe' version
   - Winzip
4. Use your unzip program to unzip the installation file. You should now have a new directory called `<confluence-root> directory>`. The `confluence-root` directory is the directory into which the Confluence application files and libraries have been unpacked (unzipped) when Confluence was installed. Confluence does not modify or store any data in this directory. This directory is also sometimes called the 'Confluence Install directory'.
   - In the rest of this document, we will refer to this as the `<Installation-Directory>`.
   - Do not use spaces in your directory path.
   - You can read more about the Confluence Installation directory.

5. Edit the `<installation-root>/confluence-init.properties` file found at:
   `<Installation-Directory>/confluence/WEB-INF/classes/confluence-init.properties`
   and update 'confluence.home' to point to your existing Confluence Home directory.
   - Make sure you have first backed up your Home directory.
   - Open the `confluence-init.properties` file in a text editor such as Notepad.
   - Scroll to the bottom and find this line:

   ```
   # confluence.home=c:/confluence/data
   ```
   - Remove the '#' and the space at the beginning of this line, so that Confluence no longer regards the line as a comment. The line should now begin with `confluence.home`.
   - Update the directory name after the `=` sign, to point to your existing Confluence Home directory.

6. If you are using Tomcat, you need to update either your `confluence.xml` or `server.xml` (depending on where you have defined the Confluence context descriptor) to point to the location of the new Confluence installation (also remember to copy over any customisations such as a tomatc datasource if you have one).

7. If you have delegated your user management to JIRA, LDAP or any other external user management system, copy the following files from your old Confluence installation to your new Confluence installation:
   - `<installation-root>/confluence/WEB-INF/classes/osuser.xml`
   - `<installation-root>/confluence/WEB-INF/classes/atlassian-user.xml` (if you are upgrading from Confluence 2.2 or later).
   - If you are upgrading from an earlier version of Confluence (2.5.5 and earlier) and are copying your existing `atlassian-user.xml` file from your previous instance, please ensure that the hibernate cache parameter in this file has been enabled, to avoid performance related issues. (NOTE: If you use Crowd for your user management, you do not need to do this.):

   ```
   <hibernate name="Hibernate Repository" key="hibernateRepository" description="Hibernate Repository" cache="true" />
   ```

8. If you have delegated your user management to Crowd, you will also need to copy the Crowd client library and configuration files from your old Confluence installation to your new Confluence installation:
   `<installation-root>/confluence/WEB-INF/lib/crowd-integration-client-X.X.X.jar`
<Installation-Directory>/confluence/WEB-INF/classes/crowd.properties. If you need more information, please refer to the Crowd documentation.

9. Restart your application server and start Confluence.

Please note that Confluence will need to re-index attachments and this can take 5-10 minutes. Please wait until Confluence has finished indexing the attachments before trying to access Confluence via your web browser. (There is no easy and quick way to determine if the indexing process is completed. Please wait for approximately 10 minutes after the server start up before accessing Confluence via a web browser.)

10. During the startup process Confluence will create any missing database indexes. If you created any database indexes on your own, please check those afterwards and remove those that duplicate the indexes added by Confluence. Just in case you run into any errors which prevent Confluence from starting up, you can set the system property hibernate.hbm2ddl.skip_creating_missing_indexes true to skip automatic index creation.

11. Visit Confluence in your web browser and log in using a username from your previous Confluence installation. You should be able to log in immediately, without seeing the Setup Wizard.

12. Take a quick look around your Confluence site to confirm that all your spaces and pages are present and everything looks normal. You should see the new Confluence version number in the page footer.

13. Consider any adjustments you need to make to customisations and special configurations, as described below.

Reapplying Customisations to your New Confluence

Hint: The steps below are for advanced Confluence users, who have applied special settings to their Confluence server and/or Confluence look and feel

After upgrading your Confluence installation to a later version of Confluence, you need to consider any customisations you have applied to your system and other special configurations:

- If you had previously installed Confluence/Tomcat as a Windows service, uninstall the service (to ensure that the old Confluence cannot start automatically when the server restarts) and reinstall the new one. For details please see Start Confluence automatically on Windows as a Service.
- If you are using a Standalone Edition of Confluence and you have previously defined a CATALINA_HOME environment variable, please check that it points to the correct path for the new Confluence Tomcat server.
- If you had previously connected your Confluence installation to an external database via a JNDI datasource or you implemented SSL, edit your new web.xml file and and copy over any relevant modifications from your old web.xml file, which relate to these customisations.
- If you were previously running Confluence on a non-standard port, edit your new <Installation-Directory>/conf/server.xml file as described in Change port for Confluence Standalone.
- If you had previously defined a Tomcat datasource, edit your new <Installation-Directory>/conf/server.xml and copy over the datasource definition from your old server.xml.
- If you were previously using any plugins, install the latest compatible version and disable any plugins that are incompatible with your new version of Confluence. The easiest way to do this is to use the Plugin Repository in the Confluence Administration Console.
- If you are using any customised themes, please check that they are displaying as expected. Some further customisation may be required to ensure compatibility with your new version of Confluence.
- If you had previously customised the default site or space layouts, you will need to reapply your changes to the new defaults as described here.
- If you had previously modified the Confluence source code, you will need to reapply your changes to the new version.
- If you were previously running Confluence over SSL, you will need to reapply your configuration as described in Adding SSL for Secure Logins and Page Security.
- If you had previously modified the memory flags (Xms and Xmx) in either the <Installation-Directory>/bin/setenv.sh or the <Installation-Directory>/bin/setenv.bat file, you may want to make the modifications in your new installation. The parameters are specified in the JAVA_OPTS variable.
- If you had changed the Confluence interface text, you will need to pull over the ConfluenceActionSupport.properties file.
- If you were using a custom SSO authenticator or the utility to Automatically Add LDAP users to the confluence-users Group, change seraph-config.xml to the correct authenticator.

Troubleshooting the Confluence Upgrade

Refer to Troubleshooting Upgrades from the Confluence Knowledge Base.

Upgrading Beyond Current Licensed Period

This page explains the recovery process should you mistakenly try to upgrade your Confluence installation to a version beyond your current license entitlement.
The information on this page applies to Confluence 2.7.2 and later.

**License Warnings**

During an upgrade an obvious indication that your license has expired can be found in your log file. You will see a 'WARN' level entry similar to this:

```
[confluence.upgrade.impl.DefaultUpgradeManager] isUpgradeAllowed
Your license is now outside of it's support period. You need to renew the license before you can upgrade to this version of Confluence.
```

When you try to connect to the Confluence instance, you will see the following warning screen:

<table>
<thead>
<tr>
<th>Time</th>
<th>Level</th>
<th>Type</th>
<th>Description</th>
<th>Exception</th>
</tr>
</thead>
<tbody>
<tr>
<td>2008-02-04 10:51:04</td>
<td>null</td>
<td>(EventType: upgrade)</td>
<td>Cannot proceed with upgrade. Your current license does not entitle you to upgrade to this version of Confluence. Please check that the support period of your license has not expired or that you have the correct partner license. If you wish to renew your license, please contact <a href="mailto:sales@atlassian.com">sales@atlassian.com</a>. If you have a new license, please enter it on this [page] and restart.</td>
<td>fatal</td>
</tr>
</tbody>
</table>

**Updating the Confluence License**

1. Contact [Atlassian Sales](http://www.atlassian.com) to arrange for a new license to be issued, as instructed on the warning screen illustrated above.
2. Once you have received a suitable license, supply the license key to Confluence:
   - Click the link given on the license warning screen, illustrated above.
   - You will first be asked to log in as a Confluence administrator.
   - Then you will be presented with a simplified license administration screen. Enter the credentials of a Confluence system administrator.
   - Copy the license key into the 'License' field and click 'Save':

```
Save
```

3. Restart Confluence to continue the upgrade.

**How to run a SQL script on your database**

This document contains some basic instructions on how to run a SQL script on your database. This document is not intended to be exhaustive of the databases we support. We still recommend that you ask your DBA to perform this task if possible.

The following examples assume a database name of yourdb and a script file called myscript.sql. Of course, the extension of the SQL script file does not have to be .sql. Any file can be used so long as it contains SQL statements.
Webserver Configuration

Apache and Apache Connector Tips

Configure Web Proxy Support for Confluence

The speed of downloading attachments is extremely slow. We are experiencing the following speeds

- Large file served directly through Apache: 15000 KB/sec
- Large file served directly from Tomcat HTTP connector: 14500 KB/sec
- Large file served from Confluence (using Apache/mod_jk/Tomcat): 84 KB/sec

You can see that the file served from Confluence is ~176 times slower!

Solution

We upgraded mod_jk from version 1.2.8 to 1.2.10 and the download speed improved significantly to ~12000 KB/sec.

Configure Web Proxy Support for Confluence

Some of Confluence's macros, such as {rss} and {jiraissues} need to make web requests to remote servers in order to retrieve data. If Confluence is deployed within a data-centre or DMZ, it may not be able to access the Internet directly to make these requests. If you find that the {rss} macro does not work, ask your network administrator if Confluence needs to access the Internet through a web proxy.

Configuring an outbound HTTP proxy in Confluence

Proxy support is configured by passing certain system properties to the Java Virtual Machine on startup. These properties follow the conventions defined by Sun:

- http.proxyHost
- http.proxyPort (default: 80)
- http.nonProxyHosts (default: <none>)

At a minimum, you need to define http.proxyHost to configure an HTTP proxy. System property configuration is described on the Configuring System Properties page.

Properties http.proxyHost and http.proxyPort indicate the proxy server and port that the http protocol handler will use.

-Dhttp.proxyHost=proxy.example.org -Dhttp.proxyPort=8080

Property http.nonProxyHosts indicates the hosts which should be connected to directly and not through the proxy server. The value can be a list of hosts, each separated by a [, and in addition a wildcard character (*) can be used for matching. For example:

-Dhttp.nonProxyHosts=*.foo.com|localhost

Note: You may need to escape the pipe character (|) in some command-line environments.

If the http.nonProxyHosts property is not configured, all web requests will be sent to the proxy.

Configuring HTTP proxy authentication

Proxy authentication is also configured by providing system properties to Java in your application server's configuration file. Specifically, the following two properties:

- http.proxyUser – username
- http.proxyPassword – secret
Authentication has a few more options in Confluence 2.10 and later, as documented below.

**HTTP proxy (Microsoft ISA) NTLM authentication (2.10 and later)**

Confluence 2.10 and later supports NTLM authentication for outbound HTTP proxies when Confluence is running on a Windows server.

To clarify, this means the {rss} and {jiraissues} macro will be able to contact external websites if requests have to go through a proxy that requires Windows authentication. This support is not related to logging in Confluence users automatically with NTLM, for which there is a user-contributed authenticator available.

To configure NTLM authentication for your HTTP proxy, you need to define a domain system property, `http.auth.ntlm.domain`, in addition to the properties for host, port and username mentioned above:

```
-Dhttp.auth.ntlm.domain=MYDOMAIN
```

**Configuring authentication order (2.10 and later)**

Sometimes multiple authentication mechanisms are provided by an HTTP proxy. If you have proxy authentication failure messages, you should first check your username and password, then you can check for this problem by examining the HTTP headers in the proxy failure with a packet sniffer on the Confluence server. (Describing this is outside the scope of this document.)

To set the order for multiple authentication methods, you can set the system property `http.proxyAuth` to a comma-separated list of authentication methods. The available methods are: ntlm, digest and basic; this is also the default order for these methods.

For example, to attempt Basic authentication before NTLM authentication, and avoid Digest authentication entirely, you can set the `http.proxyAuth` property to this value:

```
-Dhttp.proxyAuth=basic,ntlm
```

**Troubleshooting**

1. There’s a diagnostic jsp file in CONF-9719 for assessing the connection parameters.
3. Autoproxies are not supported yet. See CONF-16941.

Building Confluence From Source Code

This guide describes building a confluence.war distribution or an IDE project from the Confluence source code. Plugin developers who wish to use source code as an aid in building plugins should refer to the plugin documentation. This process should be simple and quick, so please let us know if you get stuck.

Building a WAR distribution

1. Download Confluence source code.

   Source code access is available for commercial license holders. If you do not have access to the source code download site, log in to my.atlassian.com as your billing contact or contact our sales department.

   Please be aware that while Confluence's source code is available to licensed customers, this does not apply to the Confluence Office Connector.

2. Confluence is built using Maven. Maven is bundled with the source distribution and therefore does not need to be installed separately. When you build Confluence, Maven will download dependencies and store them in a local repository. One of these dependencies requires manual installation for legal distribution reasons. If you do not already have it in your private repository, download JavaMail from Sun's website.
Sun will not allow Maven to redistribute its binaries. You must install all Sun binaries manually by downloading them from Sun's website and running the `mvn install` command. Maven has provided documentation for both 3rd party jars in general and Sun jars in particular.

Unzip the `mail.jar` file from the `javamail-1_x_x.zip` file. From the root of your extracted source code directory, run the following command, where `Path/To/mail.jar` is the absolute path to the extracted `mail.jar` file:

```bash
./maven/bin/mvn install:install-file -DgroupId=javax.mail -DartifactId=mail -Dversion=1.x.x -Dpackaging=jar -Dfile=Path/To/mail.jar
```

3. Run your build script.

If the build is run successfully you should have a `confluence.war` file created in `../<confluence-project>/dist/`.

**Option 1: Building the Confluence Project or Individual Libraries using IDEA**

This is the simplest option. From IDEA, go to File >> Open Project. Browse to the `pom.xml` file of the individual project. If you are wanting to compile the Confluence project (as opposed to one of the libraries, say Atlassian User), use the `pom.xml` file from the `confluence-project` file.

Using the `pom.xml` at the root of the distribution to load the Confluence project and all its dependencies usually results in classloading errors. If you want to debug a dependency and the confluence core together, you'll have to integrate the projects.

**Option 2: Building the Confluence Project or Individual Libraries Using Maven**

Each Confluence Library is bundled with its own Maven `pom` file. To build one of the sub-projects, you need not build the entire source. To use the bundled maven distribution:

1. Copy `build.sh` or `build.bat` to the appropriate sub-directory.
2. Change `M2_HOME` to point to the parent directory, as so:
   ```bash
   export M2_HOME="$PWD/../maven
   ```
   ```bash
   set M2_HOME=../maven
   ```

**Building an IntelliJ Idea or an Eclipse project**

1. To build a project for an IDE, you can use the instructions above, but modify the `build.sh` or `build.bat` `mvn` command. Replace:

   ```bash
   exec mvn clean package -Dmaven.test.skip $* with:
   ```

   ```bash
   exec mvn idea:idea or exec mvn eclipse:eclipse
   ```

This should leave a project file in the root of your source directory. It should have all the confluence modules.

2. Download IntelliJ IDEA.
3. Install Tomcat and get it running.
5. From Preferences > Application Servers add Tomcat
6. From Run > Edit Configurations, add a Tomcat Configuration. Select to deploy the confluence-webapp module to the appserver:

7. Click Configure and configure how to deploy. Choose to Create web module exploded directory and exclude from module content:
8. From the server tab, you might set some memory settings like:

```
-XX:MaxPermSize=256M -Xmx512m
```

9. Run the application. Have fun!

**Creating a Server for Eclipse**

In Eclipse creating a server defines creating a pointer to an existing installation of an application server.

To create a server:

- **Window->Show View->Servers**
- Right Click and select **New->Server**

In the menu bar click **File->New->Other** and expand the server folder and select the version of the server you have installed on your system. Click Next and the New Server wizard opens. This wizard defines a new server, that contains information required to point to a specific runtime environment for local or remote testing, or for publishing to an application server. By default, this field is pre-filled with the default address: localhost

Supported Servers in Eclipse:

FAQ and Troubleshooting
How to Build an Atlassian Plugin
Working with Sun Java Libraries

Confluence Architecture

Introduction

These pages are internal developer documentation for Confluence. The main audience for these documents is Atlassian developers, but hopefully plugin and extension developers might benefit from knowing more about how the application works. There are, however, a few caveats:

1. This documentation is incomplete. All system documentation is a work in progress, and more documents will come online as they are written. (This is, after all, a wiki.)
2. Confluence has been in development since 2003, much longer than these documents have existed. There are many parts of the application that do not follow these guidelines, and some of the architecture documents represent how things should be from now on rather than how they were in the past

Understanding Confluence

These documents should give you some understanding of how the Confluence code-base is structured, where to find things, and where to put new things.

• High Level Architecture Overview
• Confluence Permissions Architecture
Developer Guidelines

These documents are more general descriptions of How We Do Things Around Here. It's a good idea to be familiar with these documents, but keep in mind that no rule is set in stone, and the existence of a guideline does not absolve you from your responsibility to think.

- Spring Usage Guidelines
- Exception Handling Guidelines
- Logging Guidelines
- Deprecation Guidelines
- Hibernate Sessions and Transaction Management Guidelines
- Javadoc Standards

Anti-XSS documentation

This feature is present in Confluence 2.9 and later

This documentation is aimed at developers. It contains information necessary to get Velocity template rendering to function correctly when Confluence has the "Anti XSS mode" option enabled. This option is disabled by default in Confluence 2.9 to allow plugin developers time to adapt for any incompatibilities in their plugins and to shake out any problems in the implementation, but we hope to make it standard and mandatory in future releases.

- What is Anti XSS mode?
- Automatic reference encoding in Velocity templates
- How does it work?
- Opt-ing out of automatic HTML encoding
  - HtmlSafe method annotation
  - Method naming convention
  - Well known HTML returning methods
  - Reference naming convention
- Migration strategy for template authors
- Caveats

What is Anti XSS mode?

This mode will engage certain behaviours in Confluence intended to reduce the incidence of cross site scripting (XSS) vulnerabilities. At present this mode enables an automatic data encoding strategy designed to reduce XSS exploits arising from the incorrect encoding of data embedded in HTML templates.

Developers interested in extending this XSS protection feature to their plugins should consult the Enabling XSS Protection in Plugins document.

Automatic reference encoding in Velocity templates
Many of the past XSS vulnerabilities in Confluence have arisen simply because data from untrusted sources have not been encoded correctly when mixed with other HTML in Velocity templates. Such encoding failures lead to possible HTML injection attacks that can range from breaking page rendering, to hijacking user sessions. These security bugs will always be easily introduced when template authors have to make a conscious decision to specifically encode untrusted data when rendered. Other disadvantages of this opt-in security include a proliferation of noise in templates related directly to encoding operations ($generalUtil.htmlEncode et al) and a general obscuration of where data are being written unsafely to the client. In future releases of Confluence we will be attempting to transition to a new rendering mode where all data will be HTML encoded by default unless steps are taken explicitly to avoid this behaviour in templates.

**How does it work?**

This new mode of behaviour takes advantage of two new facilities introduced into the Velocity templating engines during the 1.4 and 1.5 releases. (Confluence originally shipped with Velocity 1.3 but was upgraded to Velocity 1.5 in the 2.7 release). In short there are two parts of the system:

1. A mechanism for marking data as being safe for HTML rendering.
2. A mechanism for encoding any data not marked as safe as it is being written to the output.

**Opt-ing out of automatic HTML encoding**

While we'd recommend that as much of your HTML markup be contained in actual Velocity templates, many templates acquire HTML markup via method calls and property access to Java objects in the Velocity context and very often the result is written directly to the output. In this situation we need to inform the Velocity renderer that these values are intended to contain HTML and should not be encoded when written. There are a few ways to accomplish this.

**HtmlSafe method annotation**

For values retrieved by calling methods or accessing properties of objects in the context, it is possible to inform the Velocity system that these values are safe to be written without encoding. This is achieved by annotating the method (whether a property getter or not) with the `@HtmlSafe` annotation.

**An annotated Java class**

```java
import com.atlassian.confluence.velocity.htmlsafe.HtmlSafe;

public class MyContextClass {
    @HtmlSafe
    public String myMarkupReturningMethod() {
        return "<b>This method returns marked up text!</b>";
    }

    public String myMethodWithAnXssExploit() {
        return "<script>alert('owned');</script>";
    }
}
```

**Using an instance of this class in a template**

```html
<ol>
    <li>$objectOfMyContextClass.myMarkupReturningMethod()</li>
    <li>$objectOfMyContextClass.myMethodWithAnXssExploit()</li>
</ol>
```

**Result when Anti-XSS is disabled**

```html
<ol>
    <li><b>This method returns marked up text!</b></li>
    <li><script>alert('owned');</script></li>
</ol>
```

**Result when Anti-XSS is enabled**

```html
<ol>
    <li><b>This method returns marked up text!</b></li>
    <li>&amp;lt;script&amp;gt;alert('owned')+&amp;lt;/script&amp;gt;</li>
</ol>
```

**Method naming convention**
Retrofitting this type of behaviour into an existing, significant codebase with an extensive plugin catalogue is very difficult and we'd like to make this new behaviour fit in as well as possible with the existing body of work. For this reason certain methods will automatically be deemed as being HtmlSafe:

- Those that start with `render` or `getRender`
- Those that end with `Html`

This strategy fits in with the observation that many of the existing methods that return HTML were named according to this convention. It also provides a mechanism for avoiding automatic encoding where Java 5 annotations are not an option.

**Well known HTML returning methods**

A few often used methods are known to return HTML by contract. These methods are therefore also treated as HtmlSafe by default.

- `com.opensymphony.util.TextUtils#htmlEncode`
- `com.opensymphony.webwork.util.VelocityWebWorkUtil#htmlEncode`

This means that any uses of these methods will behave identically whether or not the anti-XSS mode is engaged. It is important to note that `GeneralUtil.htmlEncode()` has been annotated as HtmlSafe and will also behave identically without any modification to uses in templates.

**Reference naming convention**

To cater for cases where HTML strings are built entirely in a Velocity template and then rendered, it is possible to avoid the auto encoder by using a "Html" suffix on the reference name.

**Template**

```
#set ($someHtml = "<p>This is a paragraph</p>"
#set ($some = $someHtml)

<ul>
<li>$someHtml
<li>$some
</ul>
```

**Output**

```
<ul>
<li><p>This is a paragraph</p>
<li>&lt;p&gt;This is a paragraph&lt;/p&gt;
</ul>
```

**Transitional reference name exclusion**

The velocity template reference `$body` will also avoid automatic encoding for the time being. Many templates use this convention to include whole slabs of HTML sourced from other rendering mechanisms. This exclusion is very likely to be removed in the future so it is strongly recommended that all such references be changed to make use of the standard "html" suffix as described previously.

**Migration strategy for template authors**

To ensure that your HTML markup will function correctly now and in the future here are some guidelines of working with the Anti-XSS feature:

- **Don't stop using `htmlEncode` methods just yet** – As the automatic HTML encoding feature is disabled by default it is still necessary to make sure that any unsafe data is explicitly HTML encoded before being written. Encoding the data explicitly behoves identically whether automatic HTML encoding is enabled or not. In the future we are hoping to make this the standard behaviour of templates in Confluence, allowing template authors to remove all such explicit encoding calls from templates.
- **Try to move all of your HTML markup to Velocity templates** – The more that your markup is contained in templates, the less intrusive the automatic encoding system will be. This is a good design choice in general as markup in templates is far more maintainable than static strings in Java classes.
- **Mark any other HTML data as being HtmlSafe** – methods that return HTML markup that cannot be contained in templates such as data sourced from user input or other remote retrieval need to be marked as HtmlSafe or assigned to a Velocity reference ending in the string Html before use. Consider using the HtmlFragment class for a richer, HtmlSafe description of the data that you are returning. The fewer sources of HtmlSafe data the better the security of the system.
- **Move away from relying on the transitional `$body` reference encoding exclusion** – To keep the system as consistent as possible, usages of `$body` in templates that include HTML fragments should be changed to use either a "html" suffix or the HtmlFragment class.
- **Use the system property `confluence.html.encode.automatic` to test your templates** – you can enable and disable the automatic encoding functionality in Confluence via this command line JVM system property, handy for automated test suites.
- **Raise any issues you have** – If you think we can do something better or make it easier for you to write templates and plugins that support this new mechanism we'd love to hear from you.

Developers interested in more advanced details and use-cases should consult the Advanced HTML encoding documentation.
Caveats

As much as we'd love to make the new HTML encoding system transparent to use there are a few things that you need to watch out for.

Velocity string interpolation

The Velocity configuration of Confluence allows you to use reference interpolation in any strings you construct in a Velocity template.

As can be seen from this example, automatic HTML encoding will occur when references are interpolated inside strings in the same manner as when they are written to the template output. At present there is no way to treat this case specially and you will need to make sure that any data used as part of interpolation is being treated correctly by the encoder.

String parameters

Occasionally you may have some code in your velocity template that makes a call back to some Java logic. To make sure that the value is being protected by the Anti-XSS mechanism, you must have the string evaluate within the velocity template. If not, you are passing a reference into the Java code which will not be protected.

You should write the velocity template like this:

$$object.doSomething("\$action.getValue()")$$

The quotes around the $action.getValue() call mean velocity will evaluate it before passing it into object.doSomething() and have a chance to be automatically encoded before being passed to the Java method.

Accessing action context values

Templates rendered from a Webwork Velocity result are able to access values on Webwork's action stack as if they were entries in the Velocity context. If these values are sourced from getter methods on the current action the automatic encoding system cannot detect whether the getter method has been marked as HtmlSafe. In this situation the value will be automatically encoded when rendered regardless of any annotation or method naming convention used by the source of the value.

To remedy this either use the HtmlSafe reference naming convention (e.g. assigning the action context value to a context variable ending with HtmlSafe) or retrieve the value directly from the current action via the $action reference.

Unexpected context types

Some Java code may use the Velocity context as a data passing mechanism to collect information from a template after it is rendered.

$$public class DataHolder {$$
    $$@HtmlSafe$$
    $$public String getHtml() {$$
        $$return "<strong>My html</strong>";$$
    $$}$$
$$}$$

$$myTemplate$$

$$#set ($result = data.getHtml())$$

$$Template myTemplate = getTemplate();$$
$$Context myContext = new VelocityContext();$$
$$myContext.put("data", new DataHolder());$$
$$renderTemplate(myTemplate, myContext);$$
$$String message = (String) myContext.get("result");$$

The above Java code will fail with a ClassCastException at runtime because the reference $result will not be an instance of String but an instance of BoxedValue due to the way that Confluence’s Velocity runtime handles HtmlSafe values in the Velocity context. If there is demand it is feasible for type compatibility to be restored in this situation via the use of a transparent, unboxing context layer but in general
this mechanism of information passing is discouraged. Context values that are not set from HtmlSafe sources are not affected in this situation.

**Advanced HTML encoding**

**Advanced automatic encoding topics**

**Collection inheritance**

In some cases a method may return a collection of values, each of which contain HTML markup to be treated literally in a Velocity template. If a collection returning method is marked as HtmlSafe, then all of its members will be treated as HtmlSafe as well should they be written to a Velocity template.

More precisely, a value retrieved from a HtmlSafe collection will be treated as HtmlSafe in the following situations:

- The element is retrieved via:
  - `java.util.List#get(index)`
  - `java.util.Map#get(key)`
- The element is reached via an iterator returned by `java.util.Collection#iterator()` (as is the case when a collection is used with the Velocity `#foreach` statement.)

**HtmlFragment**

One of the things that has become painfully obvious in the implementation of this system is the inadequacy of the `String` class for returning markup. The need for a HtmlSafe annotation is only necessary because a `String` return type does not convey any information about the data returned other than it is a sequence of characters. The `com.atlassian.confluence.velocity.htmlsafe.HtmlFragment` class is a type that can be used to indicate that the `toString()` method of a particular object returns markup to be interpreted as literal HTML during rendering.

```java
HtmlFragment aHtmlFragment = new HtmlFragment("<span>This string contains literal HTML</span>");
HtmlFragment anotherHtmlFragment = new HtmlFragment(new MyHtmlClass());
```

The `HtmlFragment` class' `toString()` method delegates to the wrapped object's `toString()` method and will be treated as being safe for use in HTML templates. This is useful for adding your own HtmlSafe values directly to a Velocity context or as a return type for methods returning HTML markup.

**VelocityUtils HTML detection heuristic**

The `com.atlassian.confluence.utils.VelocityUtils` class defines methods of the form `getRenderedTemplate` for convenient rendering of a template to a `String`. Unfortunately the only information available to this mechanism is the template name and Velocity context, neither of which indicate directly whether the template is to be used for HTML output. At present the rendering strategy used by these methods will try to determine whether a template contains HTML-like markup and will only employ the auto encoding mechanism should such markup be detected. It is likely that this method of template rendering will be deprecated in the short term and replaced by a more expressive, safer system.

**PossibleIncorrectHtmlEncodingEventHandler**

To help track down any Velocity reference that might be encoded incorrectly, Confluence attaches a logging event listener to the Velocity context. This event listener will print the reference name and the template that contains the reference if the reference value contains HTML like markup (either element markup or encoded entities) but the reference hasn't been marked as HTML safe. Naturally some values may contain HTML markup that are not meant to be interpreted as literal HTML, as is the case in HTML injection attacks.

This event listener will only be active if the log4j logger category `com.atlassian.confluence.velocity.htmlsafe.PossibleIncorrectHtmlEncodingEventHandler` has been set to log at INFO.

**The boxing uberspect**

Confluence employs a specialisation of Velocity's pluggable, federated introspection strategy known as an Uberspect. The Velocity runtime delegates all method calls, property accesses and iterator strategy retrieval via the configured uberspect. The default Velocity uberspect implementation provides all of the facilities to call methods and access properties of objects in the Velocity context by making heavy use of the Java reflection API. It also provides the mechanism for case insensitive property access, Velocity's map getter syntactic sugar and uses an internal introspection cache to optimise performance.

To enable the tracking of values retrieved from HtmlSafe sources, Confluence is configured to use a specialised uberspect that boxes any `ReturnValueAnnotation` annotations with the method return value. Return values from method calls that do not have any such annotations are treated exactly as before. Of course any of these uberspect boxed values may be subsequently used as arguments or targets of other method calls, so the annotation boxing uberspect is also responsible for unboxing these values before a method is executed, providing a mostly transparent operation.

For those developers who are more interested in the exact implementation details, you will want to examine the source of the classes in the new `com.atlassian.confluence.velocity.introspection` package, with the `AnnotationBoxingUberspect` being the best place to start.
Enabling XSS Protection in Plugins

This documentation is aimed at developers. In Confluence 3.0, Anti-XSS mode is enabled by default for the core Confluence application, but in order to prevent this configuration change from breaking plugins, plugin authors must opt in to extend the protection to their own templates.

- What is Anti-XSS?
- Why should I have my plugin opt in to Anti-XSS protection?
- How do I opt in to Anti-XSS protection?
- A note on naming

What is Anti-XSS?

Anti-XSS is a safeguard placed on Velocity template files that automatically HTML encodes inserted variables, therefore protecting against potential cross-site scripting vulnerabilities. It was introduced in Confluence 2.9, and enabled by default in Confluence 3.0. For more information, read the Anti-XSS documentation.

Why should I have my plugin opt in to Anti-XSS protection?

Cross site scripting is a real and dangerous security problem with many web applications. Anti-XSS protects against many potential sources of XSS vulnerabilities. Opting in to Anti-XSS protection requires very little effort, and results in a safer plugin.

Atlassian may make Anti-XSS apply automatically to Confluence plugin templates in the future, so by opting in now you save yourself from your plugin maybe breaking in a future Confluence update.

How do I opt in to Anti-XSS protection?

There are three mechanisms to mark that your Velocity template should have Anti-XSS protection applied to it:

- Give the template's filename a .html.vm suffix (i.e. mypage.html.vm)
- Place the template in a directory called html (i.e. /templates/html/mypage.vm)
- Put the Velocity directive call #htmlSafe() somewhere in the template.

If you do any (or any combination) of the above, any variable substitution performed in your Velocity template will be HTML-encoded under the rules described in the Anti-XSS documentation.

A note on naming

You may notice that the #htmlSafe() velocity directive (which causes a template to opt in to Anti-XSS protection) has the opposite meaning to the @HTMLSafe Java annotation (which causes a Java method to opt out of Anti-XSS protection). We regret this confusing naming and hope to fix it in a future release, but unfortunately we didn’t catch it in time to fix for 3.0. We will, however, ensure that #htmlSafe() continues to work.

Confluence Internals

Confluence is a large and complex application. This area documents some of the more complicated aspects of its design. For a complete reference, please refer to the source code which is available for download with all commercial licenses.

Bandana caching

Introduction
This is a technical description of Confluence's Bandana caching mechanism. It is primarily designed for Confluence developers, but published here because it might prove useful to some plugin developers.

For an overview of all of Confluence's persistence mechanisms, see Persistence in Confluence.

Confluence's Bandana subsystem is used for persisting configuration settings for Confluence and its plugins. Any persistence mechanism requires careful thought with regard to updates. Transactions are the main mechanism for controlled updates to shared data, and it's important that transactions are treated consistently across all the subsystems involved.

Confluence 2.3 has moved Bandana data to the database in order for it to be shared among clustered nodes. Using Hibernate meant that the updates done to the database were immediately transactional, but the Bandana caching layer still needed to be updated to be transaction-aware.

This document describes the caching system used by Bandana in Confluence 2.3 which allows it to deal correctly with transactional updates. The caching system may be used more extensively for other areas in Confluence going forward.

Caching layer

The caching layer for Bandana is necessary because all the data is persisted as XML. When configuration objects are retrieved from the data store, they are deserialized back into Java objects via XStream. This deserialization occurs after the XML has been retrieved by Hibernate, and is a time-consuming process. Because Bandana objects are used so frequently (at least one per request), a cache of configuration objects, independent of the Hibernate cache of XML, is required.

The interaction between the key components in the Bandana caching system is shown in the flowchart below.

Bandana caching flowchart

As you can see from the diagram, the CachingBandanaPersistor is solely responsible for reading and updating the cache, only delegating queries to the HibernateBandanaPersistor when the required data is not already in the case.

Problems to overcome

Having a cache separate to your transactional data store (Hibernate) presents a few tricky problems:

- A cache update is visible to other clients immediately; a database update is only visible to other clients once the transaction commits.
- A cache update can never be rolled back; if the associated database update gets rolled back, the cache is now inconsistent with the data.
- Two concurrent transactions which update multiple caches could interleave their changes, so that neither operation is completed in its entirety. This is one type of 'lost update' problem.
- Read-through cache updates (where a cache is empty and to be populated with data read from the database) should not result in an inconsistent cache when updates occur concurrently. This is another type of 'lost update' problem and was a serious bug in Confluence 2.2.
None of these problems is insurmountable, but the solution is fairly complex. The Bandana caching in Confluence 2.3 will have the following features:

1. Cache updates (except read-throughs) will be enacted on the Coherence cache only after the related database transaction has been completed successfully.
2. Read-through cache updates will be enacted immediately.
3. All cache updates will use locking when they are processed to prevent lost updates.
4. All cache updates will be visible when reading from the same cache during the same transaction, prior to commit.

These features are provided by a Confluence transactional cache, which is described in detail below.

**Transactional cache**

The transactional cache makes a best attempt at synchronising the data in the cache and the database when a transaction commits. A transactional cache consists of two components:

1. **Deferred operations cache**, which keeps track of update operations to an underlying cache but doesn't actually perform them.
2. **Deferred cache transaction synchronization**, which performs the deferred updates on the cache once it gets notified of a successful transaction completion.

These two components collaborate with Spring for transaction management, and the locking and caching subsystems in Confluence.

### Character encodings in Confluence

**Where character encoding is used**

There are three places that character encoding matters to Confluence:

1. **Database encoding** - usually the most important; it is where almost all user data is stored.
2. **Filesystem encoding** - important for attachment storage (pre-2.2), reading Velocity templates and writing exported files.
3. **HTTP request and response encoding** - important for form parsing, correct rendering by the browser and browser interpretation of encoded URLs.

Problems generally arise when Confluence thinks one of the above encoding is different to what it actually is. For example, Confluence might believe the database is using ISO-8859-1 encoding, when in fact it is UTF-8 encoded.

**Java character encoding**

Java always uses the double-byte UCS-2 character encoding for all char and String data. This means that each of the encodings above defines how, at that particular point, characters are converted to and from Java's native UCS-2 format into some other format that the browser, filesystem or database might understand.

So when a request comes in to Confluence, we convert it from the request encoding to UCS-2. Then we store that data into the database, converting from UCS-2 to the database's encoding. Retrieving information from the database and sending it back to the browser is the same process in the opposite direction.

**Problems with character encodings**

If Confluence has the wrong idea about encoding for one of the above, it manifests itself in different ways:

1. Incorrect database encoding - user data is corrupted between saving and restoring from the database. This often happens after a delay, as we cache data as it is written to the database and only later retrieve the corrupted copy from the database.
2. Incorrect/non-Unicode filesystem encoding - international filenames break attachment download/upload/removal (pre-2.2); exports break with international content or attachments.
3. Incorrect HTTP encoding - incorrect encoding selected by browser, resulting in incorrect rendering of characters. Changing browser encoding causes pages to render properly. Broken URLs when linking to pages or attachments with non-ASCII characters.

**Configuration of character encodings**

The **Confluence character encoding** is a configuration setting found in Administration > General Configuration, and at runtime available in Settings.defaultEncoding. It is subsequently used in the following parts of the system:

- ConfluenceWebWorkConfiguration sets webwork.i18n.encoding to the this encoding, which WebWork uses in the response Content-Type header.
- AbstractEncodingFilter sets the HTTP request encoding to this encoding. This seems unnecessary, since the Content-Type header from the client should include the encoding used. This affects form submissions and file uploads.
- VelocityUtils reads in Velocity templates using this encoding when reading templates from disk.
- AbstractXmlExporter creates its output using this encoding.
- GeneralUtil uses this encoding when doing URLEncode and URLEncoder. Different browsers have different support for character sets in URIs, so it's uncertain how much benefit this provides.

In summary, changing the Confluence character encoding will change your HTTP request and response encoding and your Filesystem encoding as used by exports and velocity templates.

The **database encoding** is the responsibility of your JDBC drivers. The drivers are responsible for reading and writing from the database in its native encoding and translating this data to and from Java Strings (which are UCS-2). For some drivers, such as MySQL, you must set Unicode encoding explicitly in the JDBC URL. For others, the driver is smart enough to determine the database encoding automatically.
Ideally, your database itself should be in a Unicode encoding (and we recommend doing this for the simplest configuration), but that is not necessary as long as:

- the database encoding supports all the characters you want to store in Confluence
- your JDBC drivers can properly convert from the database encoding to UCS-2 and vice-versa.

The *filesystem encoding* is mostly ignored by Confluence, except for the cases where the above configuration setting above plays a part (exports, velocity). When attachments are uploaded, they are written as a stream of bytes directly to the filesystem. It is the same when they are downloaded: the bytes from the file InputStream are written directly to the HTTP response.

In some places in Confluence, we use the *default filesystem encoding* as determined by the JVM and stored in the `file.encoding` system property (it can be overridden by setting this property at startup). This encoding is used by the Java InputStreamReader and InputStreamReader classes by default. This encoding should probably never be used; for consistent results across all filesystem access we should be using the encoding set in the General Configuration.

In certain cases we explicitly hard-code the encoding used to read or write data to the filesystem. Two important examples are:

- importing Mbox mailboxes which are known to be ISO-8859-1
- Confluence Bandana config files are always stored as UTF-8.

Some application servers, Tomcat for example, have an encoding setting that modifies Confluence URLs before they reach the application. This can prevent access to international pages and attachments (really anything with international characters in the URL). See configuring your Application Server URL encoding.

**Advice**

In general, **always set all character encodings to UTF-8**. That includes database, JDBC drivers, application server, filesystem and Confluence.

In certain isolated cases (e.g. Microsoft Windows), it might not be possible to use a fully Unicode filesystem (that is, a default Windows install doesn’t support Unicode filenames properly). If so, stick with UTF-8 for the other two and be aware that your operating system might have limitations around international attachments (pre-2.2), backup and restore of international data, etc.

**RELATED TOPICS:**

- Configuring Database Character Encoding
- Troubleshooting Character Encodings

**Confluence Caching Architecture**

The cache service provides centralised management of in-memory data caching within the Confluence application. Depending on which edition of Confluence you are running, the cache service may be backed by ehcache (standard edition) or Oracle Coherence (clustered edition). Because of this, it is even more important than normal that you only code to the interfaces provided by Confluence, and do not rely on any of the concrete implementation classes.

⚠️ For more information about standard and clustered editions of Confluence, please refer to the Coherence license changes document.

**The CacheManager**

The `cacheManager` bean in the Confluence Spring application context implements two interfaces: `CacheFactory` and `CacheManager`. The only method on the manager you need to worry about (unless you are maintaining the caching system as a whole) is `CacheFactory#getNameCache(java.lang.String name)`. This method will return a `Cache`.

To prevent cache name clashes, we suggest using the same reverse domain name syntax for naming caches as you would for Java class names or plugin keys. You can provide a "friendly name" for the cache management UI by providing an I18N key: `cache.name.[cache name]`.

**Unflushable Caches**

A small number of caches are configured to not be flushed by `CacheManager.flushCaches()`. These cache names are defined by the `nonFlushableCaches` bean in `cacheServiceContext.xml`. There is currently no plan to broaden this mechanism to allow plugin-specified caches to opt in to not being flushed.

**Differences Between Editions**

The differences between the standard and clustered editions of Confluence are:

- Standard edition packages the `confluence-cache-ehcache` module
- Clustered edition packages the `confluence-cache-coherence` module

Both of these modules are contained in the `cache` subdirectory of the main Confluence source tree.

Having both or neither of `confluence-cache-ehcache` and `confluence-cache-coherence` in the Confluence classpath will cause the system not to run.
Implementation

There are a couple of different places the caching subsystem hooks into the rest of Confluence.

Bootstrapping

During bootstrapping, Confluence will try to load /bootstrapContext.xml into the Spring context. This file will be found in one of the cache implementation jars. This context file is responsible for providing an implementation of the ClusterManager, ClusterConfigurationHelper and HibernateCacheFactory.

You can tell which edition of Confluence you are running by calling ClusterManager#isClusterSupported. This will return true in clustered editions, false otherwise.

Hibernate

Hibernate is configured to use the ConfluenceCacheProvider as its cache provider. This provider delegates to the HibernateCacheFactory (as defined in the bootstrap context above) to instantiate the correct cache implementation depending on the Confluence edition being run.

The Cache Manager

During main application startup, Confluence will try to load /cacheProviderContext.xml into the Spring context. This file will also be found in one of the cache implementation jars and is responsible for instantiating the correct implementation of the CacheManager.

The Cache Management UI

The user interface (and backing implementation) for viewing, flushing and adjusting the sizes of caches are implemented as plugins within each of the cache implementation jars.

Gotchas

- ehcache will log a warning if a cache is created for which it does not have an explicit configuration in ehcache.xml. We should ensure that there are no such warnings before releasing a new version of Confluence.

Confluence Internals History

A brief history of Confluence noting when major features or internal changes were introduced. See the release notes for full details.

Confluence 2.6

Redesign of recent updates, children web UI. Introduced classic theme which maintains old look and feel.

Source structure changed to fit better with Maven 2.

Confluence 2.5.5

Server ID support.

Confluence 2.5

Pages can be restricted to multiple users and/or groups.

Confluence 2.4

Editable comments.

Bundled plugins shipped in atlassian-bundled-plugins.zip, including Plugin Repository Plugin.

First release built with Maven 2.

Confluence 2.3

Clustering possible with a clustered license.

Changed from EhCache caching layer to Tangosol Coherence. This was for both application caches and Hibernate second-level caches.

Moved Bandana (configuration framework) storage from home directory (/config/) to the BANDANA table in the database.

Confluence 2.2

Structure of attachments folder in home directory changed from /attachments/<filename>/<version> to /attachments/<id>/<version> to fix CONF-4860.

Personal spaces.
Confluence 3.0 Documentation

Simpler Atlassian-User configuration when `atlassian-user.xml` replaces `atlassianUserContext.xml`.

Confluence 2.1
Confluence starts using Atlassian-User.

Confluence 2.0
Export Word documents.

Confluence Permissions Architecture

These are guidelines related to the development of Confluence. The guidelines mainly apply to Atlassian employees, but reading them should provide insight for third-party plugin developers as well, so we decided to make them public.

Permissions checking overview

In Confluence, a permission check is a question like *does user U have permission to do action A to content C?* The way we answer that question deserves a brief overview of the logical operations:

1. First, Confluence checks that the user is allowed to access the application. This involves user and group checks for user U against the defined global permissions.
2. Second, Confluence checks space permissions. This involves user and group checks for user U against the space permissions for action A for the space containing content C.
3. Finally, Confluence checks content level restrictions like page permissions. This involves user and group checks for user U against the content level permissions for action A on content C.
4. If all three checks succeed, user U is permitted to do action A to content C by Confluence.

The logical operations involved in a "user and group check for user U" look like this, taking space permissions as an example:

1. First, Confluence retrieves all the space permissions for the space containing content C from the database.
2. Next, it checks whether user U is one of the individual users that has been granted the permissions required to do action A.
3. Next, it goes through the groups with permission required to do action A, and checks whether user U is a member of any of those groups.
4. If the membership status of user U and the group isn't cached already, Confluence determines which user repository (database, LDAP, Crowd) owns the group. Confluence checks in the user repository whether user U is a member of the group, and caches the result for subsequent checks.
5. If either check succeeds – that is, if either user U or one of the her groups has permission for the action – user U is permitted to do action A to content C by Confluence.

The API used for performing all these checks is described in more detail below.

The PermissionManager API

The core API for checking permissions in Confluence is through the `PermissionManager` (javadoc). The two most important methods on this interface are:

- `hasPermission` – does user U have permission P on object O?
- `hasCreatePermission` – does user U have permission to create object of type T inside container C?

So, for example. If you have a page, and want to determine if a user is able to edit it:

```java
boolean canEdit = permissionManager.hasPermission(user, Permission.EDIT, page);
```

Or, if you want to know if user is permitted to comment on a page:

```java
boolean canComment = permissionManager.hasCreatePermission(user, page, Comment.class);
```

- Permissions are defined as constants on the `Permission` interface (javadoc). They are VIEW, EDIT, EXPORT, REMOVE, SET_PERMISSIONS and ADMINISTER.
- If the supplied user is null, the anonymous permission is checked
- For the purpose of checking create permissions, the "containing" object is not the same as the parent. You test if a page can be created in a space, and a comment within a page, not within its parent page or comment.
- There is a special object – `PermissionManager.TARGET_APPLICATION` – that represents Confluence itself and is used for checking global permissions
- Some permission checks don't make sense, for example checking if you can REMOVE TARGET_APPLICATION, or checking if you can administer a page. Checking a nonsensical permission will result in an `IllegalArgumentException`
- Similarly, if you check permissions against a type of object that the `PermissionManager` doesn't know how to check permissions against (i.e. it doesn't have a delegate for that class, see below), it will throw an `IllegalArgumentException`.

**Permission Inheritance**
The system does not cater for any inheritance of permissions. Having Permission.ADMINISTER against an object does not imply that you also have Permission.EDIT.

However, certain permissions are considered "guard permissions". For example, permission to VIEW TARGET APPLICATION is required to do anything in Confluence (it's generally referred to as "Use Confluence" permission). Similarly, permission to VIEW a particular space is required to do anything else in that space. If you are modifying Confluence permissions through the UI, removing a guard permission from a user or group will also remove any dependent permissions that user/group might have. If you are modifying Confluence permissions programmatically, you are responsible for making sure they end up in a sensible state w.r.t guard permissions.

**PermissionManager Quirks**

- The PermissionManager always checks to ensure a user is not deactivated, and that a user has the "Use Confluence" guard permission.
- The PermissionManager does not check if the user is a member of the super-user confluence-administrators group. If you want super-users to override your permission check, you have to do it manually.

**PermissionManager Implementation**

For every type of target object (or container in the case of create permissions) there is a corresponding PermissionDelegate (javadoc) that performs the actual checks. The code should be reasonably self-explanatory.

**Shortcuts**

**Getting all viewable/editable spaces for a user**

Finding all spaces for which the user has a particular permission is a common, and reasonably expensive operation in instances with large numbers of spaces. For this reason we have a number of shortcut methods on SpaceManager that go straight to the database:

- getPermittedSpaces – get all spaces for which a user has VIEW permission
- getPermittedSpacesByType – get all spaces of a certain SpaceType for which the user has VIEW permission
- getSpacesEditableByUser – get all spaces in which the user can create or edit pages
- getEditableSpacesByType – get all spaces of a certain SpaceType in which the user can create or edit pages

**Note:** These operations are still not cheap, especially in situations where the user being checked may be a member of a large number of groups.

**Searching / Lucene**

The Lucene index contains enough information for searches to determine if particular results are visible to the user performing the search. So long as you're not going direct to the Lucene index yourself, and use one of Confluence's search APIs to find content, the content returned should not require any more tests for VIEW permission.

**Checking Permissions from Velocity**

It might be difficult (or even impossible) to construct a required PermissionManager call from velocity code, especially for calls to the hasCreatePermission() method. For this reason there is an object called permissionHelper (javadoc) in the default velocity context with a number of helper methods to perform common permission checks.

If you can not find an appropriate method on the PermissionHelper, your best course of action is to write a Velocity Context Plugin to encapsulate your permission checking code (or if you're an Atlassian developer, obviously, just add it to the helper).

**Other Permission-related APIs**

**PermissionCheckDispatcher**

The PermissionCheckDispatcher allows you to check if a particular user has access to a certain Confluence URL. It will only work if the target of the URL is a WebWork action (it works by instantiating the action referred to by that URL, filling in all the relevant form values, and calling isPermitted on the action).

The PermissionCheckDispatcher used to be the preferred way of testing whether or not to display a link in the web UI. However, its use is being phased out because it can be very slow. Do not use the PermissionCheckDispatcher for new code. Instead, use the PermissionManager directly. If you are in UI code, use the PermissionHelper (javadoc), a convenience class that is placed in the Velocity context to make permission checks more Velocity-friendly.

**SpacePermissionManager**

The SpacePermissionManager is a low-level API for directly manipulating user permissions. You should not use the SpacePermissionManager for checking permissions, because it tightly couples your permission check to the internal representation of permissions in the database. Use the PermissionManager for all permission checks.

The SpacePermissionManager should only be used:

- By a PermissionDelegate to translate between a logical permission check, and the back-end implementation of that permission
- By permissions management code (i.e. granting, revoking or displaying user permissions)
Adding New Permissionable Objects

To make it possible to use a new type of object as the subject of a permissions check, you will need to:

1. Write a `PermissionDelegate` for that object's class.
2. Instantiate the delegate in Spring (delegates are defined in `securityContext.xml`).
3. Add that object to `DefaultPermissionManager`'s `delegates` property in `securityContext.xml`.

Adding New Permissions

1. Ask if this permission is really necessary? For example, a lot of things that look like they should be permissions are really "create" permissions (like "can comment on page" is really "create (comment, page)")
2. Add a new method to the `PermissionDelegate` interface.
3. For each existing `PermissionDelegate`, implement your new method. Throw `IllegalStateException` if the permission is not relevant to that delegate's object.
4. Add a new constant to the `Permission` interface to represent your permission (see the existing examples).

To Do

- Permissions checking on labels (add, remove) are broken, and still being done via page permission checks.
- We should probably throw `UnsupportedOperationException` for bogus checks instead of `IllegalStateException`.
- Currently create permissions are tested against container, not parent. A `hasCreatePermission` method could be useful.

Confluence Services

These are guidelines related to the development of Confluence. The guidelines mainly apply to Atlassian employees, but reading them should provide insight for third-party plugin developers as well, so we decided to make them public.

Here's a quick overview of some of the services defined in Confluence (for more details of what a service is, see the High Level Architecture Overview).

**Database Service**

This service is defined in `databaseSubsystemContext.xml` and `productionDatabaseContext.xml`. It provides database connectivity and Hibernate ORM to the application. The reason for splitting the service into two files is to allow for easier testing. `productionDatabaseContext.xml` extracts the database configuration from the bootstrap configuration, and brings up Confluence with the Tangosol Coherence clustered cache. If you substitute that one file with `testDatabaseContext.xml` you will instead get a pre-configured in-memory HSQL database and in-memory caching.

Because configuring Hibernate dynamically is non-trivial, the database service is unavoidably dependent on every class we want to persist via Hibernate. You can see this in the list of `.hbm.xml` files loaded in `databaseSubsystemContext.xml`.

**Bandana Service**

Provides a generic configuration/preferences storing service using XStream to serialize POJO configuration objects to XML. Confluence's bandana service persists to the database.

**Cache Service**

Provides centralised management of in-memory cached data. The backing cache implementation is provided by ehcache in the standard edition of Confluence, and Oracle Coherence in the clustered edition. For more information about the cache service, see Confluence Caching Architecture.

For more information about standard and clustered editions of Confluence, please refer to the Coherence license changes document.

**Event Service**

Provides a simple service for producing and consuming events. Defined in `eventServiceContext.xml`. Confluence's event service is cluster-aware, distinguishing between events that are limited to a single node of the cluster, and events that must be broadcast to every node.

**Plugin Service**

Provides the Atlassian plugin framework, in `pluginServiceContext.xml`. Confluence's plugin service is customised to deal with bundled plugins (plugins that are provided with the application but that may be upgraded by the end user), and to behave mostly sanely in a cluster.

The plugin system hasn't been entirely service-ised yet, as all the different plugin module loaders result in dependencies back to whatever subsystem they're being plugged into.
**Task Queue Service**

A central manager for queues in Confluence. I'm not entirely sure this should exist as it currently adds no value whatsoever beyond being a lookup mechanism, which Spring does already.

**Not Services**

Things that should be services, but aren't.

**Quartz Scheduling**

Pretty obvious next candidate for servicization, but possibly tricky because the Spring/Quartz integration might not be very friendly.

**Backup/Restore**

Something to keep in mind if we clean up the backup/restore code

**User Management**

I wasn't going to mess with user-management while there was a different atlassian-user task in the release pipeline.

**Wiki Rendering**

This seems like a reasonably trivial candidate to convert to a service. There's only one dependency on non-service code (the image renderer depends on the attachment manager).

**Mail (sending and receiving)**

The sending and receiving of email is currently a mess of singleton configurations, clients sticking mail jobs directly on the queue, and very little going through Spring at all. This should be fixed.

**External Network Access**

It would be nice to have Confluence provide a service for accessing the outside world so we can throttle number of connections, provide central configuration of time-outs and authentication, and so on.

**Image Manipulation**

Right now we have a thumbnail manager that lives with attachments, but it would be nice to make this more generic, and at least support multiple thumbnail sizes.

**Confluence UI architecture**

**Rendering frameworks**

There are two frameworks that do the template rendering in Confluence: Webwork and Sitemesh. The confusing bit is that both of them use Velocity as their templating engine. We try to distinguish them by using *.vm for templates processed by Webwork, and *.vmd for those processed by Sitemesh.

**Rendering contexts**

There are four different Velocity contexts used in Confluence:

- templates processed by Webwork use the context defined in ConfluenceVelocityContext
- templates processed by Sitemesh as a result of the \#applyDecorator() directive use the context defined in ApplyDecoratorDirective
- templates processed by Sitemesh as a result of the URL mapping in decorators.xml use the context defined in ProfilingPageFilter
- templates processed by the notification queue use the context defined in VelocityRenderedQueueItem.

The two Sitemesh contexts are pretty much the same, but the Webwork velocity context contains a lot more stuff than either of the Sitemesh ones.

**Logical structure**

The following diagram shows the logical structure of the Confluence UI.
Confluence UI Architecture - Logical Structure

Rendering pipeline

The following diagram shows the flow of control through the Confluence UI.
In more detail, the flow of control goes:

- Webwork gets request, maps request URL to action using xwork.xml
- Webwork maps response of action to a Velocity template using xwork.xml
- Webwork launches Velocity handler on template (*.vm) with context defined in ConfluenceVelocityContext
- Velocity process content in *.vm file
  - Within an `@applyDecorator()` directive:
    - Velocity calls the ApplyDecoratorDirective class with the parameters and body content of the directive
    - Any `@decoratorParam()` directives are processed by the ParamDirective class, which pushes bits of the current Velocity context into the ApplyDecoratorDirective parameters
    - ApplyDecoratorDirective matches the name parameter of the directive with a *.vmd file from decorators.xml
    - ApplyDecoratorDirective launches Sitemesh on a decorator template (*.vmd) with context defined in ApplyDecoratorDirective
    - Sitemesh returns decorated content
  - Velocity template finished processing rest of *.vm file, returns to Webwork
- Web.xml servlet filter 'sitemesh' maps to ProfilingPageFilter, a Sitemesh page filter
- Sitemesh uses the request URL mapping in decorators.xml to launch a decorator template (*.vmd) with context defined in ProfilingPageFilter
- Sitemesh returns decorated content as response.

You can find out which beans are in which context by looking in the classes above. A full list would be too long to include here. Note that even though the ApplyDecoratorDirective launches a Sitemesh decorator template, the Sitemesh template doesn't get automatic access to...
the Velocity context. The only bits that are passed through are done with the \#decoratorParam() directive.

Wow, pretty complicated. But it lets us do cool stuff like implement custom themes, apply layouts and more.

Sample page

Below is a sample decorated page with the templates responsible for the rendering indicated.

Decorated page

Date formatting with time zones

Introduction

Confluence 2.3 supports a time zone preference for a user. This means all dates in the system must be formatted using the same process to appear in the user's time zone correctly. This document describes how dates are formatted in Confluence. It may be useful to plugin developers who need to format dates in a special way inside Confluence.

DateFormatter

The new class introduced in Confluence 2.3, DateFormatter, allows formatting in the user's timezone. See the full javadoc for details, but methods include:

- String format(Date date) – Formats the date and returns it as a string, using the date formatting pattern.
- String formatDateTime(Date date) – Formats the date and returns it as a string, using the date-time formatting pattern.
- String formatServerDate(Date date) – Same as format(Date), but doesn't perform time zone conversion.

Most methods format the time in the user's time zone. The 'server' methods format the time in the server's time zone.

Accessing the DateFormatter in Velocity

In Velocity, using the DateFormatter is easy because it is in the Velocity context. In a normal Velocity template (*.vm), such as an action result, you might use it like this:

```
$dateFormatter.format($action.myBirthdayDate)
```

If you want to use the DateFormatter in a Velocity decorator (*.vmd), such as a custom layout or theme, you need to access it via its getter on the action:
Accessing the DateFormatter in code

The DateFormatter is constructed by the ConfluenceUserPreferences object, which can be obtained from the UserAccessor. The code below gives a demonstration:

```java
ConfluenceUserPreferences preferences = userAccessor.getConfluenceUserPreferences(user);
DateFormatter dateFormatter = preferences.getDateFormatter(formatSettingsManager);
System.out.println(dateFormatter.formatDateTime(date));
```

The `userAccessor` and `formatSettingsManager` are Spring beans which can be injected into your object. You can usually get the user from the context of your macro or plugin, or using `AuthenticatedUserThreadLocal.getUser()`.

# HTML to Markup Conversion for the Rich Text Editor

## Introduction

This component enables the rich Text Editor by converting HTML (created by the renderer, then edited by the user) into Confluence Wiki Markup.

It works like this:

1. Submit HTML to `WysiwygConverter.convertXHtmlToWikiMarkup`
2. ...

This document explains step 2 in some more detail. Most problems with this stage stem from difficulty in determining the correct amount of whitespace to put between two pieces of markup.

## Classes and Responsibilities

This section briefly describes the main classes involved and their responsibilities.

### DefaultConfluenceWysiwygConverter

Converts Wiki Markup to HTML to be given to the rich text editor, and converts edited HTML back to markup. Creates RenderContexts from pages and delegates the conversion operations to a WysiwygConverter instance.

### DefaultWysiwygConverter

Converts Wiki Markup to XHTML to be given to the rich text editor, and converts edited XHTML back to markup. This class contains the guts of the HTML -> Markup conversion, and delegates the Markup -> HTML conversion to a WikiStyleRenderer, with the `setRenderingForWysiwyg` flag set to true in the RenderContext.

### WysiwygNodeConverter

Interface for any class which can convert an HTML DOM tree into Markup. Can be implemented to convert particular macros back into markup. The macro class must implement WysiwygNodeConverter and give the macro's outer DIV a 'wysiwyg' attribute with the value 'macro:<macroname>'.
Aggregates text styles as we traverse the HTML DOM tree. Immutable. Responsible for interpreting Node attributes as styles and decorating markup text with style and colour macros/markup.

**ListContext**

Keeps track of nested lists – the depth and the type.

**WysiwygLinkHelper**

Just a place to put some static methods for creating HTML attributes describing links, and for converting link HTML nodes into markup.

**Overview of the HTML to Markup Conversion Process**

**Preprocessing the HTML**

1. First the incoming HTML is stripped of newlines and ‘thinspaces’, which were inserted during the rendering process so that there were places to put the cursor to insert text.
2. XML processing instructions (which can be present when HTML is pasted from MS Word) are stripped.
3. NekoHTML is used to parse the HTML into an XML document fragment.

**Converting the Document Fragment to Markup**

This uses the `convertNode` method, which has the honour of being the longest method in Atlassian (although not the most complex by cyclomatic complexity measures).

The signature of this method is:

```java
String convertNode(
    Node node,
    Node previousSibling,
    Styles styles,
    ListContext listContext,
    boolean inTable,
    boolean inListItem,
    boolean ignoreText,
    boolean escapeWikiMarkup)
```

That is, the method returns the markup needed to represent the HTML contained in the DOM tree, based on the current context (what styles have been applied by parent nodes, are we already in a table or a list and so on).

The body of this method is a large case statement based on the type of the current node and the current state. The typical case gets the markup produced by its children, using the `convertChildren` method, decorates it in some way and returns the resulting string.

The `convertChildren` method simply iterates over a node’s children calling `convertNode` and concatenating the markup returned.

In order to determine how much white space separates the markup produced by two sibling nodes we often need to know the type of each node. That is why `convertNode` takes a `previousSibling` argument. The `getSep` method takes the two nodes to be separated and some state information. It uses a lookup table to decide what type of whitespace (or other text) to use.

**Post-processing the markup**

1. Clean up whitespace and multiple newlines – the conversion process may insert too many newlines or multiple “TEXTSEP” strings to separate text – these are collapsed into single newlines and single spaces.
2. Replace `{}` style markup with simply * where possible.

**Worthwhile Style Improvements**

1. Split up `convertNode` so that it is responsible for deciding what treatment the current node needs, and then calling `convertTextNode`, `convertDivNode` etc.
2. Put the state passed to `convertNode` into an immutable object to reduce the parameter clutter. Don’t use a Map.
3. Refactor `WysiwygLinkHelper` – it’s very confusing.

**Rendering in 'For Wysiwyg' Mode**

The HTML produced by the renderer to be displayed by the Rich Text editor is not identical to that generated for display. It contains extra attributes which are cues to the conversion process. The following list isn’t exhaustive, but gives the flavour of the types of considerations involved.

1. Some errors should be rendered differently so that the original markup isn’t lost – e.g. an embedded image which can’t be found should be displayed as a placeholder, not just an error message.
2. When links are rendered extra attributes are added to the tag so that the appropriate alias, destination and tooltip can be determined. See `WysiwygLinkHelper`’s javadoc for details.
3. Some errors put the erroneous markup in a span with the “wikisrc” class, which causes its contents to be directly used as markup.
4. This speaks for itself.
5. Thin spaces are added at strategic points so that there is somewhere to place the cursor when inserting text, e.g. at the end of the page, in a new paragraph.

6. Curly brackets are treated differently: a '{' typed in the RTE is interpreted as the start of a macro tag, not as an escaped '{' – you must explicitly escape '{' and '}' in the RTE.

7. Macros.

   From a wysiwyg point of view there are four cases:
   a. Macros with unrendered bodies (or no bodies). These appear as \{macro\} ... unrendered body ... \{macro\}, so the user can edit the body text in wysiwyg mode.
   b. Macros with rendered bodies, but which the editor doesn’t ‘understand’ – that is, the editor can’t manipulate the HTML produced by the macro. These are rendered as \{macro\} ... rendered body ... \{macro\}. A macro indicates that the editor doesn’t understand it by returning true from suppressMacroRenderingDuringWysiwyg(). Most macros should do this, unless the Wysiwyg converter understands how to create a new instance of the macro. The user can edit the HTML in the body of these macros, which will be converted back to markup.
   c. Macros we fully understand. These are simply rendered as normal (but surrounded by a div or span describing them). These return false from suppressMacroRenderingDuringWysiwyg().
   d. Macros which are responsible for their own rendering. These return true from suppressSurroundingTagDuringWysiwygRendering().

8. The `bq.` markup adds an attribute to the tag to distinguish it from a blockquote tag produced by the `{quote}` macro.

9. The header DIV of panel macros is given a wysiwyg="ignore" attribute, because it is generated from the macro parameters. This means that if you edit the title of a panel macro in the RTE the change is ignored.

10. Look at the InlineHtmlMacro for an example of a macro which implements WysiwygNodeConverter.

### How To Fix Bugs

**Writing Tests**

The first thing to do is to write a failing test. At the moment all the tests are in `com.atlassian.renderer.wysiwyg.TestSimpleMarkup`. Keeping them all together is reasonable, as they run quickly and you will want to make sure that your fixes don’t break any of the other tests.

There are two types of test – markup tests and XHTML tests.

Use a markup test when you have a piece of markup which doesn’t ‘round trip’ correctly. For instance, perhaps the markup:

```
* foo
* bar
```

becomes

```
* foo
* bar
```

when you go from wiki markup mode to rich text mode and back again.

The body of the test you write would be:

```java
testMarkup("* foo\n\n* bar");
```

which will check that the markup is the same after a round trip. Note that it is OK for markup to change in some circumstances – two different markup strings may be equivalent, and the round trip will convert the starting markup to ‘canonical markup’ which renders identically to the
initial markup. There are also pathological cases where a round trip may switch markup between two equivalent strings – these should be fixed, even though they don’t break the rendering as they show up as changes in the version history.

If a bug is caused by the conversion of user-edited (or pasted) HTML into markup.  
In this case you write a test like this:

\[
\text{testXHTML("...offending HTML...", "...desired markup...")}
\]

This test first checks that the desired markup round-trips correctly, then that the HTML converts to that markup.

**Finding Problems**

Once you have written your test you need to find out what the converter is doing.

Running the test in debug mode and putting breakpoints in `testMarkup/testXHTML` is the best way of doing this. As you track down the nodes causing problems you can put breakpoints in the part of `convertNode` which handles the offending type of node.

You can also set ‘debug’ to true in `DefaultWysiwygConverter.java:44` – this will dump the XHTML produced by Neko, turn off the post-processing mentioned above, and print out details of the separator calculations in the generated markup string.

So you might see:

\[
\begin{array}{l}
\text{[li-li}
\text{false,false]}
\end{array}
\]

which means that two list items, not in a table and not in a (nested) list get separated by a newline. You can tweak the table of separators as needed.

**HTTP authentication with Seraph**

**Introduction**

This document describes how the default security system in Confluence works, using the Seraph library for HTTP authentication.

Extending the security system by subclassing Seraph’s authenticator and configuring the `seraph-config.xml` file is outside the scope of this document. See [Single Sign-on Integration with JIRA and Confluence](#).

**Flowchart diagrams**

The easiest way to understand Confluence’s authentication process is with the following diagrams.

Because the `Authenticator.login(request, response, username, password, rememberMe)` method occurs three times, and is slightly complex, it has been broken into its own sub-flowchart.
Supported authentication methods

The default Seraph authenticator supports four methods of authentication, as can be seen in the flowchart:

- request parameters: os_username and os_password
- session attribute storing the logged-in user
- cookie storing username and password ('remember me' login)
- HTTP basic authentication via standard headers.

Each method is tried in the order above. A successful login at an earlier method continues without checking the later methods. Failure at one method means continuing with the later methods until all are exhausted. At this point, the user is considered an anonymous user, and treated according to the permissions of an anonymous user in Confluence.

Looking through the source code will show that Seraph supports role-based authentication, but this is only used in Confluence for the /admin/ URL restriction.

I18N Architecture

This document sheds some light on how Confluence looks up a message text from one of the resource bundles.

Loading of Resources

Currently the only implementation of the I18NBean interface is the DefaultI18NBean. When it is instantiated, it attempts to load resources from the following locations:

1. Load /com/atlassian/confluence/core/ConfluenceActionSupport.properties and /external-links.properties and create a CombinedResourceBundle containing both of them.
2. Load all language pack resources which match the current user's locale, which would be:
   - /com/atlassian/confluence/core/ConfluenceActionSupport_<country_lang_variant>.properties
   - /com/atlassian/confluence/core/ConfluenceActionSupport_<country_lang>.properties
   - /com/atlassian/confluence/core/ConfluenceActionSupport_<country>.properties

Warning
The files are only loaded if a language pack for the specific locale is installed.

3. Load all resources of type 'i18n' which match the current user's locale:
   - <resource location>_<country_lang_variant>.properties
   - <resource location>_<country_lang>.properties
   - <resource location>_<country>.properties
   - <resource location>.properties

Resource Bundle Structure

DefaultI18NBean internally creates a list of CombinedResourceBundles per locale, combining resource bundles from language packs and i18n resources of the same locale. When you call one of the DefaultI18NBean.getText() methods it will go through the bundles in the following order:

1. country_lang_variant
2. country_lang
3. country
4. default
On a lookup of a combined resource bundle, the last occurrence of a given key takes precedence during the lookup, which results in the following lookup order:

1. i18n resource
2. language pack

The order within i18n resources and language packs with the same locale is not defined, as they are loaded from the plugins which are loaded in an arbitrary order. This is not an issue in most cases, as you usually have no overlapping keys between your resources anyway.

**Example**

Given the following situation:

- The current user's locale is 'de_DE_foo'
- There are language packs installed for the locales 'de_DE_foo', 'de_DE' and 'de'
- There is one resource of type 'i18n' available from one of the plugins. The location for that resource is 'com.example.resources'

The resource bundle structure would look like this:

![Resource Bundle Structure Diagram]

Lookups will always happen from top to bottom until a message for a given key is found.

**RELATED TOPICS**

Confluence Internals

**Page Tree API Documentation**

This documentation is aimed at developers needing to include page-tree (page reordering) functionality in their Confluence or Plugin code.

Let's start with an example - editing a page deep inside the Confluence Doc space.

This tree is generated by the following markup in listpages-dirview.vm:

```html
#requireResource("confluence.web.resources:jquery")
#requireResource("confluence.web.resources:page-ordering-tree")
<div id="tree-div"></div>
```

and the following JavaScript:
Once you understand the above code you'll have a good overview of how the tree works.

Stepping through the code

To start, "expandedNodes" is simply a JS array of objects with "pageId" variables. The pagelDs are populated using Velocity but any method is okay.

Next, \$jQuery(function (\$) { is just a way of enabling \$ to be used to gain access to a jQuery object. The page tree code has been written as an extension of the jQuery object, so we call \$("#tree-div") to get a jQuery object wrapping the div with id "tree-div" that we added to our HTML markup.

Creating the tree

When the tree() function is called, an object with options is passed. We'll work through each of the options in turn:

url

This is the location that the tree will load its nodes from as the user navigates it. The alternative is to directly include the tree data in the HTML in nested <ul> or <ol> format.

initurl

(optional) This is the location that the tree will load its "trunk" (initial nodes) from. If not specified, the "url" will be used and the server would
be expected to return something useful. If specified, it can (as in this case) pass extra information to the same server address.

parameters

(Optional but important) This array specifies the key/value pairs that will be sent to the URL when making node requests. The nodes returned from the server will be expected to include key/value pairs for each of the parameters in the array, which are stored in the tree internals and sent with any future requests from that node.

append, insertabove, insertbelow

(Optional) These options specify callback functions that should be executed when their respective event occurs:

- append - means that a tree node (i.e. a page) has been moved inside another node
- insertabove - means that a tree node has been moved above another node
- insertbelow - means that a tree node has been moved below another node

For each of these events the most important data is source and target. Source is the node that is being moved and target is the "other" node that the source is interacting with.

While these three events are the most common, you can also hook callbacks to:

- grab - when the user clicks and holds on a node
- drag - when the user moves the mouse while a node is grabbed
- drop - when the user releases the mouse button
- nodeover - when a node is dragged over another node
- nodeout - when a node is dragged out of a node it was previously over
- onready - covered next

onready

(Optional) Called when the tree has finished loading, from either its first initUrl call or from hard-coded list data. In this case, if "expandedNodes" exist the tree should be expanded to show them. The way that this is done is worth explaining in more detail.

Finding and Expanding Nodes

Once the first level of tree data has been loaded into the browser, the next step is often to drill into the tree to expose a particular element. This is done by calling:

tree.expandPath(expandedNodes, callback)

Internally, this function works recursively through the array of expandedNodes, locating the node in the loaded tree and, if present, opening it. In the screenshot above, this is equivalent to passing an array of nodes:

"Confluence Documentation Home", "Confluence Development Hub", "Confluence Architecture", "Confluence Internals". Note that the nodes are referenced by pageId and must be in the correct order - each node to expand must already be loaded. Once each node is expanded the callback function (if present) is executed. In this example, the callback highlights a node inside the expanded nodes - note that the "Bandana caching" node is only loaded from the server when the "Confluence Internals" node is expanded, so the highlighting must occur after this.

Individual nodes are located with this syntax:

tree.findNodeBy(attribute-name, attribute-value)

Usually the attribute-name will be one of the parameters in the options originally used to create the tree; in this case it is "pagId".

The object returned by findNodeBy has a number of functions that can be called on it:

- open(callback) - expand this node. If the node has not been opened yet and the tree has a url, child-node JSONs will be requested from the server and appended to the node.
- close() - closes an opened node
- getAttribute(attrName) - returns the attribute value for the given name (eg "pagId")
- setAttribute(attrName, attrValue) - sets an attribute
- highlight()- adds "highlighted" class to the node
- makeDraggable()- allows the node to be moved in the tree
- makeUndraggable()- stops the node from being moved (e.g. when moving a page while editing, other nodes in the tree cannot be moved)
- setText(text) - updates the node text
- append(node) - appends a node to this node
- below(node) - places the passed node after this node
- above(node) - places the passed node before this node
- remove() - removes this node from the tree
- reload() - if this node has children, reload them from the server
Other tree functions

In addition to the functions covered in the example above, the tree object exposes the following variables and functions:

- options - the options passed in the original tree() function call
- reload() - clears and rebuilds the tree
- append(node) - appends a node to the tree root

Password Hash Algorithm

Confluence uses an algorithm to hash local users' passwords. The result for the password 'admin' is:

```
x61Ey612Kl2gpFL56PT9weDmpSo4AVj8+qx2AuTHdRyY036xxzTTrw10Wq3+4qQyB+XURPWx1ONxp3Y3pB37A==
```

The encryption algorithm is based on BouncyCastle's SHA1-512 implementation. You can see one version of the source code for it [here](#). The entire Confluence source code is available [here](#).

If you'd like to try to import users from a different user management system into a local instance of Confluence, you're likely to be better off using a different solution than re-hashing existing passwords. Some options would be:

1. Use Crowd, which is extendable and offers connectors to user repositories.
2. Import users using their plain text passwords, leveraging the Remote API Specification. One good client is the Confluence Command Line Interface.

Persistence in Confluence

There are three main persistence APIs which are used in Confluence:

1. Hibernate - database persistence, difficult to extend.
2. Bandana - XML persistence, easy to use in plugins. Stored in database in Confluence 2.3+, or in Confluence home directory in 2.2.x and earlier.
3. Content properties - database persistence for properties associated with a piece of Confluence content.

Because Bandana is the primary persistence API used by plugin developers, it will be covered in more detail below.

Hibernate

Confluence uses the open source persistence framework Hibernate. Confluence 2.2.x uses Hibernate version 2.1.8.

Each object to be persisted has a *.hbm.xml file which sits in the same directory as the associated class in the Confluence web application. For example, Label.class has an associated Label.hbm.xml which describes how label objects will be persisted. The particular details vary from class to class, but typically include:

- the database table used to hold the data (Confluence bootstrap creates these tables if they do not exist)
- the column names and mappings to class attributes
- any special queries used for functionality in Confluence (for example, to retrieve a list of personal labels)

All this data is expressed in the standard Hibernate mapping format. In some cases, there is a single mapping file for all subclasses of a particular class. For example, ContentEntityObject.hbm.xml includes mappings for pages, news, mail and space descriptions.

The Hibernate mapping files are listed in mappingResources bean in applicationContext.xml.

Although it might be possible to extend Confluence's database through Hibernate, this is not recommended. There are a few downsfalls with extending our Hibernate configuration:

1. You need to maintain your forked copy of the hibernate mappings file against each new version of Confluence
2. Your new hibernate objects will not be protected from (or necessarily upgraded to) any changes we make in the schema in future versions
3. Unless you really understand our code, something weird will happen.

Avoid using Confluence's database to store custom data – use content properties or Bandana instead.

Bandana

Bandana is an Atlassian framework for persistence which uses XStream to convert arbitrary Java objects into XML for storage. The concepts used in Bandana are very simple:

- Bandana stores data in contexts. In Confluence, there is one global context, and one context per space. The relevant class is ConfluenceBandanaContext.
- Each context stores key-value pairs. The key is a String and the value can be any Object (it should typically implement Serializable).
Based on this design, the BandanaManager has methods for storing and retrieving values from a context by key:

- `void setValue(BandanaContext context, String key, Object value)` - store a value against a key in the Bandana context.
- `Object getValue(BandanaContext context, String key)` - get a key's value from the Bandana context. Returns null if no matching context and key exists.
- `Object getValue(BandanaContext context, String key, boolean lookUp)` - same as above, except if `lookUp` is true and the context is a space context, this method will also check the global context if no matching key is found in the space context.

For plugins, it is recommended to use a key for your Bandana values that includes the full package name of your plugin. For example, a theme plugin might use a key like `org.acme.confluence.mytheme.importantPreference`.

Prior to Confluence 2.3, this XML was written to the filesystem in the Confluence home directory. The file `config/confluence-global.bandana.xml` stores the global context, and there is a file `config/spaceKey/confluence-space.bandana.xml` with the configuration for each space. In Confluence 2.3 and above, Bandana data is written to the `BANDANA` table in the database, with three columns for context, key and an XML-serialized value.

To get access to the BandanaManager from your plugin code, normally you only need to include a private BandanaManager field with an associated setter method. Spring will automatically call the setter method before the first time your plugin is called.

```java
public class MyMacro extends BaseMacro {
    private BandanaManager bandanaManager;

    // setter called by Spring
    public void setBandanaManager(BandanaManager bandanaManager) {
        this.bandanaManager = bandanaManager;
    }

    // main method of macro
    public String execute(...) {
        // do stuff with bandanaManager
        return "...";
    }
}
```

Content properties

Another form of persistence, content properties are key-value pairs associated with a ContentEntityObject and stored in the database.

### Spring IoC in Confluence

**Introduction**

The Spring Framework provides an inversion of control (IoC) container that Confluence uses for managing objects at runtime. This document provides an overview of how this relates to Confluence, specifically focused at the needs of plugin developers and those extending Confluence.

**If you're looking for the quick overview** on how to access Confluence managers from your plugin, check out Accessing Confluence Components From Plugin Modules.

The purpose of an IoC container is to manage dependencies between objects. When you go to use an object in Confluence it will have all its dependencies ready and available to use. For example, calling a method on a PageManager will typically require a PageDao to work correctly. Spring ensures that these dependencies are available when they are needed, with a little bit of guidance from us.

**Spring contexts**

Confluence uses a number of Spring contexts to separate our objects into discrete subsystems. The contexts are declared as servlet context parameters in `confluence/WEB-INF/web.xml`. The snippet below shows the Spring contexts listed in `web.xml` for Confluence 2.3:
What this means is there are 13 context XML files in the Confluence classpath which specify the objects in Confluence which are managed by Spring. When I say 'in the Confluence classpath', in practice I mean they live in `confluence/WEB-INF/classes/`. The biggest and most important is `applicationContext.xml`, which we'll have a look at now.

Bean declarations

Around line 100 in the Confluence 2.3 `applicationContext.xml`, you'll find the `schemaHelper` bean as a good example:

```xml
<bean id="schemaHelper" class="bucket.core.persistence.hibernate.schema.SchemaHelper">
  <property name="mappingResources">
    <ref local="mappingResources"/>
  </property>
  <property name="hibernateConfig">
    <ref bean="hibernateConfig"/>
  </property>
</bean>
```

The bean has an ID for Spring to reference it (`schemaHelper`), a class name which will be used to automatically create the bean (`bucket.core.persistence.hibernate.schema.SchemaHelper`), and a number of properties. In this case, the properties are references to other beans in the current context, `mappingResources` and `hibernateConfig`.

Because we use the setter injection method in Confluence, this declaration means two things about the SchemaHelper Java class:

- it must have a public no-args constructor
- it must have two public methods: `setMappingResources()` and `setHibernateConfig()`. Both these must take one argument which is an interface implemented by the appropriate bean.

Other than these two requirements, the SchemaHelper class can be any normal Java class. It can have other constructors, other public methods, and can implement or extend any interface or class that you like.

The purpose of registering a bean in Spring is two-fold:

1. When you access the SchemaHelper bean through Spring, it will have its mappingResources and hibernateConfig dependencies injected before you use it.
2. You use the bean as a dependency elsewhere, to automatically get it injected into your own class (more on this below).

Autowiring

In the bean declaration for `schemaHelper` bean above, each property has the same name as the Spring bean which is used to satisfy it. For example, the `mappingResources` property uses the `mappingResources` bean, which is set by the `setMappingResources()` method on the `schemaHelper`. Spring provides a shortcut for leaving these declarations out, called autowiring.

For example, the declaration for `themeManager` bean is marked as autowire 'byName' (near line 1000):

```xml
<bean id="themeManager" class="com.atlassian.confluence.themes.DefaultThemeManager" autowire="byName" />
```

Looking at the `DefaultThemeManager` class, we see it has four setter methods:

1. public void setBandanaManager(BandanaManager)
2. public void setEventManager(EventManager)
3. `public void setGlobalTheme(String)`
4. `public void setPluginManager(PluginManager)`

Spring looks at the names of the four methods, tries to find beans with IDs of 'bandanaManager', 'eventManager', 'globalTheme', and 'pluginManager'. If they exist, it calls the setter method with the relevant bean as an argument.

In this case, methods 1, 2 and 4 will be called by Spring to inject dependencies. Method 3 (setGlobalTheme) is just a setter used for something else, not called by Spring. This is the drawback of autowiring: it is slow and can waste time trying to find dependencies uselessly.

Using autowiring reduces the need for writing a lot of XML, and also provides a method of dependency injection for objects which aren't registered in the Spring context XML files like plugin modules.

Plugin dependency injection

Almost all Confluence plugin types are autowired. This means, if your macro plugin needs to access a Confluence page, it can simply do so like this:

```java
public class MyMacro extends BaseMacro {
    private PageManager pageManager;

    public String execute(Map parameters, String body, RenderContext renderContext) {
        // ...
        Page page = pageManager.getPage(spaceKey, pageTitle);
        // ...
    }

    // ... implement other methods ...

    /**
     * Called by Spring to inject pageManager
     */
    public void setPageManager(PageManager pageManager) {
        this.pageManager = pageManager;
    }
}
```

Autowired components must use the interfaces used by the manager to work with different versions of Confluence. The implementing class used for various managers may change over time, but the bean ID and interface will be preserved.

Internally, the way the components are autowired is via Confluence's `ContainerManager`. You can also do this with your own objects if required:

```java
ContainerManager.autowireComponent(object);
```

Accessing Spring beans directly

If you need access to Confluence managers or other Spring beans without autowiring your class, you can use the `ContainerManager` directly. For example, to get the `pageManager` bean:

```java
PageManager pageManager = ContainerManager.getComponent("pageManager");
```

You should always use autowiring in preference to this method because it makes your code easier to change and easier to test. Inside Confluence this method is sometimes required to break circular dependencies.

Transaction proxy beans

Confluence uses Spring's transaction handling by wrapping some objects in transaction proxy beans.

Technical Overview of Clustering in Confluence

- **Overview of clustering documentation**
  Refer to the overview of Confluence clustering in the Administrators' Guide.
any copy and see the same information. While we have tried to make clustering Confluence as easy and administrator-friendly as possible, it is a major architectural change and requires extra planning for deployment and upgrades.

This document will give a technical overview of clustering in Confluence 2.3, primarily for those users and developers who will be installing and configuring Confluence in a cluster. A separate overview is available for Confluence plugin developers.

Cluster topology

A simple description of the cluster topology for Confluence would be multiple applications, shared data source. A cluster of Confluence consists of:

- multiple homogeneous installations of Confluence (called nodes below)
- a Confluence home directory for each installation.
- a distributed Oracle Coherence cache (formerly known as Tangosol Coherence), which all nodes use via a multicast group - see networking summary below
- a single database, which all nodes connect to

The user is responsible for configuring an appropriate HTTP load balancer in front of the clustered installations. Typically this means using mod_jk or another application server load-balancing technology. The load balancer must be configured to support session affinity.

Communication between clustered nodes is minimised by using a distributed cache which propagates updates to all other nodes automatically. Where necessary, Coherence provides a locking mechanism for synchronising jobs and a RMI interface for more complex communication.

LAN Clustering Only

Atlassian only supports clustering over a local area network. While it is theoretically possible to configure Confluence to cluster across a WAN, the latency involved is likely to kill performance of the cluster. We can't stop you trying, of course, but you're going to have to work out how to configure Coherence yourself, and we're not going to support the resulting mess.

Homogeneous Confluence installations

All the Confluence installations must be running exactly the same application, down to the lowest level. Items that must be the same include:

- Confluence version
- Application server version
- JDK version
- Libraries and plugins in the Confluence classpath, WEB-INF/lib
- Libraries in the application server classpath

The installation section has more information how to ensure homogeneous node installations.

Creating a Confluence cluster

When installing Confluence in a clustered setup, you will be responsible for configuring your web server and load balancer to distribute traffic between each node. No additional software is required as Coherence is bundled with Confluence.

Here is an overview of the process:

1. Obtain a clustered licence key from Atlassian for each node
2. Upgrade a single node to the clustered licence
3. Start the cluster from that node's administration menu, specifying a name and optionally a preferred network interface
4. Restart the single node and test it
5. Copy the Confluence application and Confluence home directory to the second node
6. Bring up the second node and it will automatically join the cluster.

Copying the Confluence application and home directory helps ensure that the installations are homogeneous.

An alternative to this method is to copy the Confluence web application, but not the Confluence home directory. In this case, the installation wizard will require your cluster name to connect to the other nodes, and it will automatically configure itself. You will need to rebuild the index manually after this installation, however.

There is now full documentation for a Confluence Cluster Installation.

Upgrade process

Another consequence of the homogeneous requirement is that upgrades must be done by following a strict process.

1. All cluster nodes are brought down
2. Upgrade a single node to the latest Confluence version  
3. Start the single node so it can upgrade the database  
4. Upgrade subsequent nodes and start them one-by-one.  

This is the only safe method of upgrading a Confluence cluster.

Single database

The Confluence database in a cluster is shared by all nodes. This means that the database must be able to scale to service all the Confluence nodes, which will probably mean implementing some kind of database cluster and JDBC-level load balancing. We can not offer support with scaling or tuning your database, you will need to talk to your DBA or database vendor.

For obvious reasons, you must have an external database to run Massive - you can not cluster Confluence when using the embedded HSQL database.

The most important requirement for the cluster database is that it have sufficient connections available to support the expected number of application nodes. For example, if each Confluence instance has a connection pool of 20 connections and you expect to run a cluster with four nodes, your database server must allow at least 80 connections to the Confluence database. In practice, you may require more than the minimum for debugging or administrative purposes.

In a cluster, attachments must be stored in the database. Configuring a cluster in an existing installation will automatically migrate your attachments to the database. Non-clustered installations still have the option of using the Confluence home directory for storing attachments.

While attachments are stored in the database, they are temporarily written to the cluster node's local filesystem, designated <confluence-home>/temp folder, when being streamed to users (so Confluence doesn't have to hold open database connections unnecessarily). For this reason, Confluence will still need enough temporary disk space to hold any attachments currently in transit.

Distributed cache

In a normal configuration, Confluence uses many caches to reduce the number of database queries required for common operations. Viewing a page might require dozens of permissions checks, and it would be very slow if Confluence queried the database for this information with every page view. However, caches must be carefully maintained so they are consistent with the application data. If the page permissions change, the old invalid data needs to be removed from the cache so it can be replaced with a fresh correct copy.

To preserve consistent caches across a cluster, Confluence uses a distributed cache called Oracle Coherence, which manages replicating cache updates transparently across all nodes. The network requirements of the distributed cache are quite simple, but must be preserved if the cluster is to work properly.

To discover other nodes in the cluster, Confluence broadcasts a join request on a multicast network address. Confluence must be able to open a UDP port on this multicast address, or it will not be able to find the other cluster nodes.

Once the nodes are discovered, each responds with a unicast (normal) IP address and port where it can be contacted for cache updates. Confluence must be able to open a UDP port for regular communication with the other nodes.

Because the Coherence network requirements are different to those required by the Confluence database connection, the situation can arise where Confluence can use the database but not talk to the other nodes in the cluster via Coherence. When Confluence detects this, it will shut itself down in a cluster panic.

For more details on the network configuration of the distributed cache, see the networking summary

Home directory

Confluence's home directory has a much-reduced role in a cluster. Because the application data must be shared between all nodes for consistency, the only information stored in the Confluence home directory is either node-specific, or needed to start Confluence. This includes information related to:

- database connection
- license
- cluster connection

The only application data stored in the Confluence home directory is the Lucene search index. Confluence synchronises this data itself by keeping track of indexing tasks in the database.

This is also why we recommend copying the Confluence home directory from the first node when setting up subsequent nodes. If you did not copy the Confluence home directory, you would need to rebuild the search index from scratch on the subsequent nodes after installation.

Event handling

Broadcasting events to all nodes in a cluster is supported in Confluence, but not recommended. The cluster topology uses a shared data store so that application state does not need to be synchronised by events.

The event broadcasting is done only for certain events, like installing a plugin. When a plugin is installed in one node, Confluence puts the plugin data in the database, and notifies the other nodes that they need to load the plugin into memory.

Indexing

Confluence maintains a copy of its Lucene search index on each node of the cluster. This index is used for many things beside full-text searches, including RSS feeds and lists of recently updated content. Indexing in a cluster works like this:
1. Node 1 gets a request to save some page update
2. After saving the page in the database, Node 1 adds a "page-updated" index entry to the queue, which is in the database
3. Periodically, each node picks up the "latest entries" from the queue, where what is latest is determined from a timestamp on a file in the Confluence home directory which indicates when the queue was last inspected. This process is called "flushing the index queue".
4. Each node independently updates its local Lucene index. The "page-updated" index entry is internally changed into a delete-document task and an add-document task to apply the changes to Lucene.
5. Each node updates the timestamp on its index-queue-timestamp file to reflect the most recent processing or "flushing" of the index queue.

Because of step #3, if the timing of the nodes is not synchronised or changes sporadically (due to a virtualisation environment, typically), index changes will not be correctly synchronised in the cluster. This is the most common cause of index sync problems in clusters.

If a node is disconnected from the cluster for a short amount of time (less than three hours), it will be able to bring its copy of the index up-to-date when it rejoins the cluster. If a node is down for a long amount of time and its lucene index has become stale as a result, you may want to avoid the expensive operation of rebuilding the index. To do that, you must copy a "live" version of the Lucene index from an active node. Simply replace the contents of the Confluence Home/index directory with those from an active node before bringing the stale node back up.

**Job synchronisation**

For tasks such as sending the daily report emails, it is important that only one node in the cluster does this. Otherwise you would get multiple emails from Confluence every day.

Confluence uses locks in the Coherence distributed cache to ensure only one node can be running certain jobs at a time. This ensures email notifications will only be sent once.

**Activity tracking**

Activity tracking does not work in a cluster, and will be disabled for clustered deployments. We're working on making the activity tracker clusterable in a future release. You can follow this issue. You can try some other options for tracking usage.

**Cluster panic**

In some situations, there can be a network issue or firewall that prevents the distributed cache from communicating but still allows Confluence to update the database. This is a dangerous situation because when the caches on the detached nodes become inconsistent, users on different nodes will see different information and updates can be lost.

Confluence can detect this problem by checking a database value against a cached value, and if they differ, all the clustered nodes will be shut down with a 'Cluster panic' message. This is considered a fatal error because the consequences can cause damage to your data. For those administrators that like to live on the edge, there is a system property to prevent cluster panic and allow data corruption. For more information, see Cluster safety mechanism.

If a cluster panic does occur, you need to ensure proper network connectivity between the clustered nodes. Most likely multicast traffic is being blocked or not routed correctly. See the networking summary below.

**Summary of network requirements**

In addition to normal connectivity with its database, all clustered Confluence instances require access to a multicast group and the ability to open a UDP unicast port.

By default, the multicast address is automatically generated from the cluster name you provide when starting the cluster and the multicast port is fixed. During cluster setup, Confluence will prompt for the unicast IP address to use if the server has multiple network interfaces, and by default the unicast port is fixed. The cluster multicast group will be joined on the same network interface as the bound unicast IP address.

For any settings which are not configurable through the Confluence web interface, they can be configured via an XML file in the Confluence home directory for more exotic networking requirements.

**Scaling Confluence On A Single Server**

Since the maximum addressable memory on a 32 bit JVM is 4GB, some large servers may scale Java applications by running JVM instances concurrently. This would be implemented as separate, clustered Confluence nodes running on a single server and communicating internally. Because each JVM replicates the cache entirely, it may be useful to test a single, massive instance running a 64 bit JVM as an alternative. This configuration may result in superior performance than an internal cluster.

**Geographically Distributed Clusters**

Collocating nodes is strongly recommended as high latency will almost certainly degrade performance due to the overhead of cache replication. Cluster nodes will provide the best performance if servers are physically adjacent. However, as long as all nodes share a LAN, users may wish to test alternative configurations to see how performance is affected.

**Cluster safety mechanism**
Introduction

A mechanism was added in Confluence 2.3 and above to ensure database consistency when running multiple cluster nodes against the same database. This is called the cluster safety mechanism, and is designed to ensure that your wiki cannot become inconsistent because updates by one user are not visible to another. A failure of this mechanism is a fatal error in Confluence and is called cluster panic.

Because the cluster safety mechanism helps prevents data inconsistency whenever any two copies of Confluence running against the same database, it is enabled in all instances of Confluence, not just clusters.

How cluster safety works

A scheduled task, ClusterSafetyJob, runs every 30 seconds in Confluence. In a cluster, this job is run only on one of the nodes. The scheduled task operates on a safety number — a randomly generated number that is stored both in the database and in the distributed cache used across a cluster. It does the following:

1. Generate a new random number
2. Compare the existing safety numbers, if there is already a safety number in both the database and the cache.
3. If the numbers differ, publish a ClusterPanicEvent. Currently in Confluence, this causes the following to happen:
   - disable all access to the application
   - disable all scheduled tasks
   - update the database safety number to a new value, which will cause all nodes accessing the database to fail.
4. If the numbers are the same or aren't set yet, update the safety numbers:
   - set the safety number in the database to the new random number
   - set the safety number in the cache to the new random number.

How to fix it

Cluster Panic

Usually presents itself with the following error message:

```
FATAL [DefaultQuartzScheduler_Worker-4] [confluence.cluster.safety.ClusterPanicListener]
handleEvent Fatal error in Confluence cluster:
Database is being updated by an instance which is not part of the current cluster. You should
check network connections between cluster nodes, especially multicast traffic.
```

In almost all cases, cluster panic events are caused by two or more instances of Confluence (in separate clusters) updating the same database. Such events are typically caused by one of the following issues:

JVM paused (e.g. while swapping memory) can break communication between two nodes

Always watch the swapping activity of your server and avoid swapping due to lack of RAM. If there is not enough RAM available, your server may start swapping out some of Confluence’s heap data to your hard disk. This will slow down the JVM’s garbage collection (GC) considerably and affect Confluence’s performance.

- In clustered installations, swapping can lead to cluster panic. This is because swapping causes the JVM to pause during garbage collection, which in turn can break the inter-node communication required to keep the clustered nodes in sync.

Two instances of Confluence have been started in your application server

This is one of the most commonly encountered issues. The strangest case of this that we have seen so far involved a cloned image of a PC running Confluence that was later used in a remote office in a different city. The people using Confluence on the cloned instance were not aware that the original Confluence instance was also running and that both these Confluence instances were using the same production database server.

- Solution: Check your application server's configuration to make sure that multiple copies of the application server are not running concurrently. Database transaction logs can help identify the location of other application servers, if client IP addresses are recorded along with each transaction.

Two copies of your application server are running

Sometimes starting an application server twice will result in two processes running, even though only one can be accessed over the network.

- Solution: Check a list of running processes (for example, with the `ps` command in Posix-based operating systems like Linux, Unix and Mac OS X) and make sure your application server is only running once.

Networking failure between nodes in the cluster

- Solution: Check that multi-cast traffic is being transmitted successfully, and that the network between your nodes is low-latency (<100 ms).

Database server stops responding

If Coherence fails to retrieve the SafetyNumber from the database, the comparison will fail. If it fails to update it, the next comparison will fail, 30 seconds later.

Many things can cause this, including a scheduled shutdown for backups, network failure, a filled-up transaction-log partition and a changed password on the account used by Confluence to connect to the database.
Solution: resolve the problem with the database (or network), then restart Confluence

In all cases, when starting Confluence after a cluster panic, you must ensure all cluster nodes have been shut down completely. If necessary, use commands like `ps` and `kill` to get a list of Java processes and terminate them manually.

Please visit this document for troubleshooting advice if you encounter any of the above situations.

Technical details

The cluster safety number in the database is stored in the `CLUSTERSAFETY` table. This table has just one row: the current safety number.

Velocity Template Overview

Velocity is a server-side template language used by Confluence to render page content. Velocity allows Java objects to be called alongside standard HTML. Users who are writing User Macros, plugins or customised PDF exports may need to modify Velocity content. General information is available from the Velocity user guide.

Useful Resources

- Customising Layouts
- Disable Velocity Caching
- Basic Introduction to Velocity
- What’s the easiest way to render a velocity template from Java code?
- Working With Decorator Macros

Basic Introduction to Velocity

Example Usage

A variable in velocity looks like this:

```
$foo
```

To set a variable:

```
#set ($message = "Hello")
```

A basic `if` statement:

```
#if ($message == "Hello")
  Message received and is "Hello"
#end
```

A velocity variable which evaluates to null will simply render as the variable name. See the Velocity User’s Guide

## Confluence Objects Accessible From Velocity

The complete list of objects available for use are:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Doc Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>$body</td>
<td>The body of the macro (if the macro has a body)</td>
<td></td>
</tr>
<tr>
<td>$param0-n</td>
<td>The parameters passed to your macro (as available)</td>
<td></td>
</tr>
<tr>
<td>$param&lt;name&gt;</td>
<td>Named parameters passed to your macro (as available)</td>
<td></td>
</tr>
<tr>
<td>$config</td>
<td>The BootstrapManager object, useful for retrieving Confluence properties</td>
<td>BootstrapManager</td>
</tr>
<tr>
<td>$content</td>
<td>The current ContentEntity object that this macro is a included in (if available)</td>
<td>ContentEntityObject</td>
</tr>
<tr>
<td>$space</td>
<td>The Space object that this content object is located in (if relevant)</td>
<td>Space</td>
</tr>
<tr>
<td>$generalUtil</td>
<td>A GeneralUtil object, with useful utility methods for URL encoding etc</td>
<td>GeneralUtil</td>
</tr>
<tr>
<td>$action</td>
<td>A blank ConfluenceActionSupport object, useful for retrieving i18n text if needed</td>
<td>ConfluenceActionSupport</td>
</tr>
<tr>
<td>$webwork</td>
<td>A VelocityWebWorkUtil object, for its htmlEncode() method</td>
<td>VelocityWebWorkUtil</td>
</tr>
<tr>
<td>$req</td>
<td>The current HttpServletRequest object (if the page is rendered as a result of an HTTP request)</td>
<td>HttpServletRequest</td>
</tr>
<tr>
<td>$res</td>
<td>The corresponding HttpServletResponse object (not recommended to be played with)</td>
<td>HttpServletResponse</td>
</tr>
<tr>
<td>$userAccessor</td>
<td>For retrieving users, groups and checking membership</td>
<td>UserAccessor</td>
</tr>
<tr>
<td>$permissionHelper</td>
<td>For determining user rights</td>
<td>PermissionHelper</td>
</tr>
</tbody>
</table>

### Editing Files within JAR Archives

#### Configuration Files Location

With the release of Confluence 2.6.0, many files have been moved inside the main .jar file, which means they can no longer be edited by simply opening and saving a file.

#### Background

For those not familiar with the terminology, a .jar file is a Java ARchive file. It's like a Unix .tar file (or a Windows .zip file), and is managed by a very similar command-line tool `jar` which is included with the JDK. Essentially, it takes several files, or an entire directory structure, and compresses them together into a single file. This saves a little space, and makes it much easier to manage that group of files as a single unit. The terms "file" and "archive" can be used interchangeably in this context, as they refer to the same collection of bytes.

#### Instructions

To edit a file that exists inside a .jar file, you need to unpack the archive, perform the desired edits, then re-pack the archive:

- For a shortcut, drop the file in the WEB-INF/classes directory, creating the appropriate parent directories if necessary. This will take priority over what's in the jar file and allow you to edit the file more easily.
Special Note for Websphere

It's a bit inconvenient to modify files - add patches or configure velocity or xml files - if you have to rebuild and redeploy the war file. Websphere requires deploying Confluence as a built .war archive originally. After that, however, you can drop files in the exploded war directory and restart the application in the Websphere Console to pick up changes. For the case of Velocity (vm or vmd) files or jsp files, you don't even need to reload the application - just refresh your page!

A typical exploded war directory might be found in a path similar to:

```
/usr/lib/IBM/WebSphere/AppServer/profiles/AppSrv03/installedApps/serverName-laptopNode01Cell/confluence-2.10.2.war/confluence-2.10.2.war/
```

Keep in mind that this isn't a technique for deploying war files, but rather for modifications after deploy.

Unix or Linux

1. Shut down Confluence
2. Create a new working directory, e.g. /tmp/confluence-working
3. cd into that directory
4. Extract the contents of the `jar` file. To edit the main confluence jar:
   ```bash
   jar xf $CONFLUENCE/confluence/WEB-INF/lib/confluence-2.6.0.jar. You now have a directory structure, or at least a set of files, which are the contents of the .jar archive.
   ```
5. Edit the file or files
6. Ensure the original .jar is not in the working directory. If you copied or moved it there for unpacking, delete it or move it elsewhere, to prevent it becoming part of the new archive.
7. Repack the archive: from within the working directory, issue the command:
   ```bash
   jar cf /tmp/confluence-2.6.0.jar *. You now have a directory structure, or at least a set of files, which are the contents of the .jar archive.
   ```
8. Copy the new .jar into <confluence-install>/confluence/WEB-INF/lib/. Make sure the old version of the jar has been removed.
9. Restart Confluence

Windows or OS X

If you're familiar with the command line, you can use the Unix instructions above on a Windows or OS X system as well. Alternatively, you can use just the OS User Interface:

1. Shut down Confluence
2. Copy the .jar file at <confluence-install>/confluence/WEB-INF/lib/confluence-x.y.z.jar file.
3. Extract the contents of the .jar file using an unzipping utility like Winzip, 7-zip, Stuffit or the OS X Archive Extractor.
4. Edit the file or files
5. Ensure the original .jar is not in the working directory. If you copied or moved it there for unpacking, delete it or move it elsewhere, to prevent it becoming part of the new archive.
6. Repack the archive: from within the working directory, rezip the files using your utility. Make sure you are zipping the contents of the file, not the "confluence-x.y.z" parent folder that encloses all the files.
7. Take a backup copy of the original .jar file. It's often convenient to leave it in the main Confluence directory and just rename it to something like confluence-2.6.0.jar.original. Make sure the file name does not end with a .jar extension.
8. Copy the new .jar into <confluence-install>/confluence/WEB-INF/lib/. Make sure the old version of the jar has been removed.
9. Restart Confluence

Installing Patched Class Files
Where are the files that used to be in my Confluence installation directory?

Rendering Velocity templates in a macro

When writing a macro plugin, it's a common requirement to render a Velocity file included with your plugin. The Velocity file should be rendered with some data provided by your plugin.

The easiest way to render Velocity templates from within a macro is to use `VelocityUtils.getRenderedTemplate` and simply return the result as the macro output. You can use it like this:

```java
public String execute(Map params, String body, RenderContext renderContext) throws MacroException {
    // do something with params ...
    Map context = MacroUtils.defaultVelocityContext();
    context.put("page", page);
    context.put("labels", labels);
    return VelocityUtils.getRenderedTemplate("com/atlassian/confluence/example/sample-velocity.vm", context);
}
```
Confluence UI Guidelines

These are Atlassian's internal guidelines, published for the reference of plugin developers. More thorough documentation can be found in the Plugin development guide. Not all of these guidelines are followed throughout Confluence yet, but they set the direction of our future work in the product's front-end.

Separation of content, presentation and behaviour

It is imperative that functionality in Confluence separate content, presentation and behaviour for maintainable front-end code. This means the following:

- HTML content goes in Velocity files. No CSS or JavaScript goes in Velocity files. Not even in style or onclick attributes.
- CSS styles go in CSS files.
- JavaScript code goes in JS files. JS files must be static and not generated by Velocity or any other mechanism.

The remainder of this document describes how to achieve this in Confluence.

Naming Conventions

At the moment we have two simple naming rules:

- use dashes for HTML element ids or class names e.g. comment-actions
- use camel cases for variables, method names in javascript e.g. commentToggle()

Markup

Wherever possible, use meaningful tags in your markup and do not use markup for formatting (e.g. `<strong>`) or layout (e.g. `<table>`). For example, the following markup is suitable for the File menu in an application:

```html
<h3 class="menu-title">File</h3>
<ul class="navigation menu">
  <li id="menu-item-new-window"><a href="#">New Window</a><span class="shortcut">N</span></li>
  <li id="menu-item-new-tab"><a href="#">New Tab</a><span class="shortcut">T</span></li>
  ...
</ul>
```

The use of meaningful tags, rather than a sea of tables and divs make it rendering the page without stylesheets possible, and provide better degradation in mobile browsers, Internet Explorer, and so on.

Assign classes and IDs that allow you to style the content appropriately. Use multiple classes in markup when required, but be aware that IE has limitations with parsing style selectors including multiple classes. Ensure IDs are unique within the page or Javascript code will not be able to access the elements properly.

Do not use inline script and style tags. Put them in separate CSS and JS files and use `#requireResource` to tell the WebResourceManager that you require a particular resource on this page. Note, this macro does not generate the actual markup but is done in `conf-webapp/src/main/webapp/decorators/includes/header.vm` via `$webResourceManager.getResources()`.

Including Web Resources

Confluence web resources (css & javascript) are now all defined in a System Web Resources plugin under `confluence/src/etc/java/plugins/web-resources.xml`. You should no longer use the `#includeJavascript` macro that generates inline script tags wherever you invoke it. You should now use `#requireResource(pluginKey:webResourceKey)` to tell the WebResourceManager that you require a particular resource on this page. Note, this macro does not generate the actual markup but is done in `conf-webapp/src/main/webapp/decorators/includes/header.vm` via `$webResourceManager.getResources()`.
Currently, we don't have a way to indicate dependencies between the web resources. For example, it would be nice to define in the web resource module 'ajs web depends on yui-core'. The work around at the moment is to explicitly make calls to \#requireResource in the order you would like the resources to be included. Multiple calls to the same web resource does not result in multiple includes of that resource, but rather the WebResourceManager will try to maintain the 'order' in which the resources were called. This is why you may see duplicate chunks of \#requireResource scattered throughout Confluence.

For more information about the declaration and inclusion of web resources, see: Including Javascript and CSS resources.

Stylesheets

No more site.css.vm

We no longer have the huge site.css.vm velocity template. This has been split up into separate css files:

- master.css, master-ie.css, wiki-content.css and more (see master-styles web resource module)
- default-theme.css
- colors.css.vm

The only dynamic styles in Confluence are the colors set by colour schemes, hence all color styling was extracted into colors.css.vm.

We also have a separate stylesheet for the setup wizard, setup.css.

Stylesheet ordering

CSS resources are included in the following order:

1. Confluence default styles (resources included via calls to \#requireResource such as master.css)
2. Colour scheme styles
3. Theme styles

Colour scheme and theme styles are also included in the header via the combined.css action call. It essentially produces a set of imports to other css resources, hence the name 'combined'.

Sample output of combined.css

Note, the old monster main-action.css (i.e. StylesheetAction) has now been deprecated and split into separate actions.

Style guidelines

Use the shortest form wherever possible. That means using three character colours, combined margin declarations, simple selectors, and so on:

Avoid child selectors like ul > li. Instead use a class name of "first" for compatibility with IE. (You can use child selectors if you want to intentionally exclude IE, however.)

When designing a new section of Confluence, consider using a style reset to clear out default styles for lists, paragraphs and so on.

Internet Explorer stylesheets

Very often, it's desirable to serve custom styles to Internet Explorer. Confluence web resources can be marked as 'ieOnly' in order to be rendered in conditional comments only parsed by IE.
See Including Javascript and CSS resources for more details and an example of how to do this.

**Print stylesheets**

Stylesheet web resources can be include a `media` parameter with a value of `print` to have media="print" included on their `<link>` tag so they are only used for printing. See the master-styles web resource in Confluence's web-resources.xml for an example. Any media type will be passed directly into the link tag, so you can also provide styles for handheld, projector media types, etc. as supported by your user’s browsers.

See Including Javascript and CSS resources for more details and an example of how to do this.

### JavaScript

#### JavaScript guidelines

Use closures to prevent unnecessary variables and functions being exposed in the global scope. For example, the code below binds an onclick handler to a button in the page without exposing itself or its variables in the global scope:

```javascript
jQuery(function ($) { // I am a closure, hear me roar!
  var i = 0;
  function increment() { alert(i++); }
  $('button.counter').click(increment);
});
```

Don’t introduce new global variables in JS. Rather put them under some namespace such as `AJS.Editor.MyGlobalVariable`.

Don’t mix Velocity and Javascript code. See Passing dynamic values to Javascript if you need to pass dynamic values to Javascript.

#### Atlassian.js (AJS)

To avoid depending on a particular JavaScript library too much, we have atlassian.js ("AJS") as an abstraction on top of each particular library’s functions. In Confluence 2.9, AJS wraps jQuery so many functions work in the same style as that library. Throughout Confluence’s JavaScript, we should use AJS to make common function calls such as `$.toggleClass` etc. wherever possible. This enables us to easily change the underlying JavaScript library later on if necessary.

#### Event Handlers

In the past, we have used embedded event handling like (horribly) so:

```html
<tr bgcolor="ffffff" onMouseOver="style.backgroundColor='f0f0f0'"
  onMouseOut="style.backgroundColor='ffffff'"
  onclick="javascript:checkRadioButton('themeKey.default');">
  ...<tr bgcolor="ffffff" onMouseOver="style.backgroundColor='f0f0f0'"
  onMouseOut="style.backgroundColor='ffffff'"
  onclick="javascript:checkRadioButton('themeKey.default');">
```

We are now moving to binding event handlers in javascript, using the jQuery's `bind` function.

```javascript
AJS.toInit(function () {
  AJS.$('#markupTextarea').bind("click", function () {
    storeCaret(this);
  });

  AJS.$('#markupTextarea').bind("select", function () {
    storeCaret(this);
    storeTextareaBits();
  });

  AJS.$('#markupTextarea').bind("keyup", function () {
    storeCaret(this);
    contentChangeHandler();
  });

  AJS.$('#markupTextarea').bind("change", function () {
    contentChangeHandler();
  });

  AJS.$('#submit-buttons').bind("click", function (e) {
    AJS.Editor.contentFormSubmit(e);
  });
});
```

You may have noticed in the above example, all the binds are wrapped in a `AJS.toInit()` function. This is only necessary if you require the code to be fired after DOMReady.
Unfortunately, we haven’t been able to port all the embedded event handler code to Javascript. If you encounter such code during development, please fix it up as you go 😊

Using jQuery directly

For advanced dynamic functionality, you can use jQuery directly. However, we don’t allow jQuery to set the global $ variable (which is still used by Prototype.js), so you should use the jQuery’ global variable as shown below.

To use jQuery properly in a JS file, do the following:

```javascript
jQuery(function ($) {
    // your code goes here
    // use '$' for jQuery calls
});
```

Passing dynamic values to Javascript

We are now trying remove inline scripts that are scattered throughout Confluence. Most of these inline scripts are in the velocity templates so dynamic values such as i18n strings and values from actions can be used in the script. We now have a way around this via AJS.params. You simply need to define a fieldset in your template with classes “hidden” and “parameters”. AJS will automatically populate itself with the inputs defined in the fieldset.

Example from page-location-form.vm

```html
<fieldset class="hidden parameters">
    <input type="hidden" id="editLabel" value="{$action.getText('edit.name')}">
    <input type="hidden" id="doneLabel" value="{$action.getText('done.name')}">
    <input type="hidden" id="showLocation" value="{$action.locationsShowing}">
    <input type="hidden" id="hasChildren" value="{$helper.action.page.hasChildren()}">
    <input type="hidden" id="spaceKey" value="{$action.space.key}">
    <input type="hidden" id="pageId" value="{$pageId}">
    <input type="hidden" id="actionMode" value="{$mode}"
    <input type="hidden" id="parentPageId" value="{$parentPage.id}">
</fieldset>
```

With the above code, you would use the above i18n edit label by calling AJS.params.editLabel in your javascript.

If your i18n message includes variables in the form {0}, {1}, etc. which are meant to be populated by JavaScript values, you can use the AJS.format() function to present them. For example:

```javascript
$('.draftStatus').html(
    AJS.format(AJS.params.draftSavedMessage, time) // "Draft saved at {0}" 
);
```

The second and subsequent arguments to AJS.format replace all instances of {0}, {1}, etc. in the first argument, which must be a String.

Deprecation Guidelines

⚠️ These are guidelines related to the development of Confluence. The guidelines mainly apply to Atlassian employees, but reading them should provide insight for third-party plugin developers as well, so we decided to make them public.

Because Confluence doesn’t have an official API yet, you should assume that any change you make to manager interfaces, model objects, services, or really any commonly used code will in some way impact third-party plugin developers. As such, we should always be careful to deprecate, rather than remove old functionality.
Deprecation

All deprecated methods in Confluence MUST include, as the first thing after the `@deprecated` tag, the text "since n", where n is the version number at which the tag was added, followed by either a short explanation of why the method should not be used, or a direction to use a different method.

Rationale

Because we want to keep third-party developers happy, we should deprecate methods that may be used by plugins instead of just deleting them. **However**, deprecated methods pollute the namespace, and keeping them around indefinitely just encourages people to continue to use them.

Therefore, we should record when a method has been deprecated, and before each major release we should remove anything that has stayed deprecated for more than six months or two major versions (whichever is longer).

Examples

For a simple redirect, the deprecation tag is the only Javadoc the method should require. Developers should consult the doc for the linked alternative to find out more about what the method is likely to do:

```java
/** @deprecated since 2.3 use {link Space#isValidSpaceKey} */
boolean isValidSpaceKey(String key);
```

For a "this is no longer the right way to do things" deprecation, a longer explanation may be required, and the old Javadoc may need to be retained for developers who are still stuck doing things the old way for some reason. A short explanation is put in the deprecated tag itself, and the detail is put in the main body of the Javadoc:

```java
/**
 * Return all the content a user has authored in this space.
 * <b>Warning:</b> This method has been deprecated since Confluence 2.1 because it is
 * insanely inefficient to do in the database. You should migrate your code to use the
 * SmartListManager instead, which will get the results from Lucene.
 * @deprecated since 2.1 use the [link SmartListManager] for complex queries
 */
List getContentInSpaceAuthoredBy(String spaceKey, String username);
```

When Not to Deprecate

In some situations, maintaining deprecated methods may be impossible. For example:

**You should never deprecate when...**

- The underlying model has changed, rendering any client of the old code obsolete. For example if you move from `Permission getPermission()` to `List getPermissions()`, the former method would return dangerously incorrect information if it were maintained, and thus should be deleted.
- The old way of doing things is dangerous. For example, if `userManager.getAllUsers()` is being removed because it kills the server, we should not feel guilty forcing plugins to upgrade to the safe way of doing things.

**You should make a judgement call when...**

- There would be significant effort required to maintain parallel, deprecated way of doing things for six months
- You would be forced to write an ugly API because all the "right" method/class names are taken up with deprecated methods (assume the new way of doing things will stick around forever)

DTDs and Schemas

This page is intended to host custom DTDs and schemas used internally by Confluence.

Exception Handling Guidelines
These are guidelines related to the development of Confluence. The guidelines mainly apply to Atlassian employees, but reading them should provide insight for third-party plugin developers as well, so we decided to make them public.

Randomly sorted guidelines.

1. Don’t catch `Exception` unless that’s all you’re having thrown to you.
2. Don’t declare that you throw `Exception` ever.
3. Both rules #1 and #2 apply to `RuntimeException` as well.
4. Don’t catch `Throwable` if you want to continue breathing.
5. Rule #4 applies to `Error` and any subclasses of `Error` as well.
6. Don’t catch, log and rethrow.
7. Familiarise yourself with the standard `RuntimeException` subclasses (IllegalStateException, IllegalArgumentException, UnsupportedOperationException, IndexOutOfBoundsException), and use them in preference to creating your own runtime exception class.
   - For example, if the problem is that an object reference (or "pointer") which you didn’t expect to be null is in fact null, why not throw a `NullPointerException`?
8. If you explicitly throw any `RuntimeException` in a method, document it in the method’s `@throws` Javadoc like you would a checked exception.

**Meaningful exceptions**

Where possible create, document and throw meaningful unchecked exceptions. For example, write this:

```java
public class MyGroupManager
{
    /**
     * @throws InvalidGroupException if the group cannot be handled
     */
    public void handleGroup(Group group) throws InvalidGroupException
    {
        if (!isValidGroup(group))
            throw new InvalidGroupException("Group is invalid: " + group.toString());
        // do something with the group
    }
}
```

In preference to this:

```java
public class EvilGroupManager
{
    public void handleGroup(Group group)
    {
        if (!isValidGroup(group))
            throw new RuntimeException("Group is invalid: " + group.toString());
        // do something with the group
    }
}
```

The latter implementation is not as good because it gives the calling code very little discretion as to what kind of exceptions it wants to handle.

**Hibernate Sessions and Transaction Management Guidelines**

These are guidelines related to the development of Confluence. The guidelines mainly apply to Atlassian employees, but reading them should provide insight for third-party plugin developers as well, so we decided to make them public.

**Transaction Management**

Transaction demarcation is provided by Spring, with a few wrinkles.

- We wrap managers in transaction interceptors, but not DAOs.
- We use whatever the default isolation level is for whatever database we’re connecting to.
- We commit the transaction manually between performing an action, and displaying the view.

The last point is necessary because in some cases, we were sending redirect responses to the browser *then* committing the transaction. A
quick browser would request the redirect page before their transaction was committed, and view stale data as a result. By committing the transaction before we render the view, we make sure that everything we expect to be in the database is in the database before the browser has a chance to re-request it.

**Hibernate Sessions**

Sessions are a Hibernate construct used to mediate connections with the database.

The session opens a single database connection when it is created, and holds onto it until the session is closed. Every object that is loaded by Hibernate from the database is associated with the session, allowing Hibernate to automatically persist objects that are modified, and allowing Hibernate to implement functionality such as lazy-loading.

**Disconnected Objects**

If an object is evicted from its session (for example via a clear, see below), or the session is closed while the object is still kept alive, the object is "disconnected" from the session. A disconnected object will continue to work so long as you don't perform any operation that it needs to go back to the database for, such as accessing a lazily-loaded collection.

If you see a `LazyInitializationException`, it means that a Hibernate-managed object has lived longer than its session.

Managed objects are not portable between sessions. Trying to load an object in one session then save it into another session will also result in an error. (You can use `Session.load()` or `Session.get()` to re-introduce an object to a new session, but you're much better off fixing whatever problem is causing you to try to move objects between sessions in the first place.

**Caching**

Storing hibernate objects in caches is a bad idea. By definition, a hibernate-managed object placed in a cache will outlive its session. Even if caching such an object is safe now, it's quite likely that in the future we might switch some of its properties to be lazily-loaded, or change code-paths so that properties that were previously being loaded before the object was cached aren't being loaded any more. The `LazyInitializationException` errors that result rarely show up in tests, and are hard to diagnose and fix.

Hibernate maintains its own second-level cache (shared between Confluence nodes via Tangosol Coherence) that does not suffer from this problem. Use it in preference to manually caching Hibernate data.

If you need to cache information from Hibernate, don't cache the Hibernate objects themselves. A useful alternative is to cache the object's ID and class, and then retrieve the object in the context of the current session using `Session.get(class, id)`. ID lookups go straight through Hibernate's own second-level cache, so there is (hopefully) efficient. The `getHandle()` and `findByHandle()` methods of the `AnyTypeObjectDao` provide a helpful API for doing just this.

**Flushing and Clearing**

When the session persists its changes to the database, this is called "flushing". During a flush, each object associated with the session is checked to see if it has changed state. Any object with changed state will be persisted to the database, regardless of whether the changed objects are explicitly saved or not. You can configure Hibernate's flush behaviour, but the default (`FlushMode.AUTO`) will flush the session:

- When you manually call `flush()` on the session
- Before Hibernate performs a query if Hibernate believes flushing is necessary for the query to get accurate results
- When a transaction is committed
- When the session is closed.

How long a flush takes is a function of the number of objects associated with the session. Thus, the more objects you load during the lifetime of a session, the less efficient each query will be (as a flush will generally be done prior to each query). If you have some long-running operation that gets slower and slower as it runs, it's possible that the Hibernate session is the cause.

Operations that cycle through large numbers of objects may want to periodically `clear()` their session. Clearing will dissociate all objects from the session, so they won't build up making flushing slower and slower. **Clearing a session does not flush it first**, so you'll want to flush manually or you will lose any pending, unsaved changes.

**Multi-threading**

Hibernate sessions are not thread-safe. Not only does this mean you shouldn't pass a Hibernate session into a new thread, it also means that because objects you load from a session can be called from (and call back to) their owning session, you must not share Hibernate-managed objects between threads. Once again, try to only pass object IDs, and load the object freshly from the new thread's own session.

Spring's transaction management places the Hibernate session in a ThreadLocal variable, accessed via the `sessionFactory`. All Confluence DAOs use that ThreadLocal. This means that when you create a new thread you no longer have access to the Hibernate session for that thread (a good thing, as above), and you are no longer part of your current transaction.

**The Session In View Filter**

Confluence uses the "Session in view" pattern for managing Hibernate sessions. The `SessionInViewFilter` opens a Hibernate session which is then available for the entire web request. The advantages of this is that you avoid session-related errors:

- The session lifecycle is uniform for every request
- Hibernate objects remain "alive" for the whole request, thus you can still retrieve lazily-loaded data in Velocity templates
The disadvantages are:

- Each request monopolises a database connection from the moment a request comes in, to the last byte sent to the client
- Each session will end up associated with every object that is loaded for the duration of the request
- Developers are often caught out by the way sessions behave when threads haven't come in through the web tier (i.e. Quartz jobs)

Non-Web Requests

Non-web requests do not automatically have a Hibernate session to work with, because they don't come in through the Session In View Filter. This includes start-up events, quartz jobs, and any long-running task that spawns a new thread. As a result, a new session will be opened when you make a call to a transaction-managed Spring object, and closed when that call returns.

A very common programming error in this context is to retrieve a collection of objects from a manager, then do something to each object. The moment the call to the manager returns, all objects will be detached from their containing session. If you try to do anything to them after that, you won't get the result you expected. I'm not sure if this sequence diagram helps, but here goes...

---

**High Level Architecture Overview**

These are guidelines related to the development of Confluence. The guidelines mainly apply to Atlassian employees, but reading them should provide insight for third-party plugin developers as well, so we decided to make them public.

---

**The Disclaimer**

This document represents the ideal arrangement of components in Confluence. This architecture should be the target of our refactoring, and should inform any new features we add to the system.

---

**The Goals**

For the first three years of its development, little attention was paid to the high-level structure of the Confluence application. As such, it grew organically and developed interesting quirks on the way. This document tries to make sense of Confluence from a high level, to make the application easier to work with, easier to explain and easier to extend.
The goals are:

- Clearly defined separation of concerns
- Clearly defined interfaces between components
- Clearly defined dependencies between components
- Easier integration testing of components
- Looser coupling

The Metaphor

Imagine an operating system.

- At the lowest level you have the bootstrap code, which is required for going from a state of having nothing, to one where the rest of the system can be loaded.
- At the next level, the operating system provides device drivers, network abstractions and the like, generic services that any application can use.
- On top of those services you might run an application

Bootstrap

The Confluence Bootstrap Process is responsible for bringing up enough of Confluence that the rest of the system can be loaded. In Confluence’s case, this involves:

- Locating the confluence home directory and the confluence.cfg.xml file
- Determining whether the system is set up or not
- Determining if we need to join a cluster or not
- Loading the database connection configuration (either from the config file, or from the cluster)

Based on this information, the bootstrap process can determine what to do next, and provide enough configuration for the core services that they know how to start up.

Bootstrap is implemented as a Spring context, in bootstrapContext.xml. It is loaded as a parent context to any subsequent Spring context. It is available as a static singleton from BootstrapUtils.

Setup (a digression)

Confluence’s in-browser setup requires a number of components that aren’t used anywhere else. For example it needs a dummy plugin manager so that i18n works before we have a real plugin manager available. Ideally, setup should be a separate Spring context that is loaded when setup is required, and disposed of when setup is complete.

Currently this is not the case - setup components are loaded as part of the bootstrap context and remain indefinitely. To fix this will need some work on the atlassian-setup component, which annoyingly conflates setup and bootstrap.

The Main Spring Context

Once the system has been bootstrapped, and setup has (at least) reached the point where we know how to connect to the database, the main spring context is loaded as a child of the bootstrap context. The main Spring context, available as a static singleton from ContainerManager, contains the remainder of Confluence’s Spring configuration, loaded from a lot of different XML files in WEB-INF/classes.

The list of XML files to load for the main Spring context is defined in the contextConfigLocation parameter in web.xml.

Loading these files in some specific order (as parent/child contexts) might make sense as a way of enforcing component boundaries, but I’m not convinced the benefit is worth the effort.

See also: Spring Usage Guidelines

Services

These are generic services that you might consider useful to any application, like database access, caching, plugins, events, indexing/searching, and so on. A good way to think of the service layer is to imagine a theoretical library called "atlassian-base", consisting only of Confluence’s bootstrap and service layers, which could be used as the basis for any new Atlassian web application.

Services can have dependencies on the bootstrap manager, and on each other, but there should never be a circular dependency between services, and there should never be a tightly coupled dependency between a service and application code.

Interdependencies between services should be minimised. When introducing a dependency between services, ask if this dependency is necessary or incidental.

Services are defined in XML config files in WEB-INF/classes/services.

- One file per service
- Each file should have a header comment describing the service, and explicitly declaring any dependencies on other services
- Each file should be divided into "PUBLIC" and "PRIVATE" sections, delineating which components are part of the service’s public façade, and which are only for internal use
- All beans defined in services must be explicitly wired. No autowiring.

In the future, once the service system has been bedded down, we might introduce some kind of naming convention for private beans to make
it harder to use them accidentally outside the context.

Confluence Services

Subsystems

Below the service layer is the Confluence application itself, which is divided into subsystems. More on this when I know what to do with them myself.

Javadoc Standards

These are guidelines related to the development of Confluence. The guidelines mainly apply to Atlassian employees, but reading them should provide insight for third-party plugin developers as well, so we decided to make them public.

New Standard

Much of the Confluence codebase does not yet conform to this standard. Confluence developers should help the Confluence codebase out by bringing any code they touch into line with this standard.

Read Me First

You really, really should read the Sun guide to writing Doc comments: http://java.sun.com/j2se/javadoc/writingdoccomments/, especially the advice about avoiding phrases like “This class...” or “This method...”

The Rules

- All classes must have a doc comment
- All public constants must have a doc comment
- All public methods must have a doc comment except:
  - Methods that implement or override a method in an interface or superclass without adding any interesting behaviour beyond what is already documented for the overridden method
  - Trivial getters or setters

A trivial corollary to the above rule: all methods declared in an interface must have doc comments.

Things You Should Document

- Any side-effects of the method should be clear from the doc comment
- @param tags for each parameter, even if the content is trivial
- @returns tag for the return value, even if trivial
- What type of object will be contained in any returned collection
- What happens if any of the arguments supplied to the method are null (saying “Should never be null” in a {{@param}} is sufficient if the behaviour is undefined, but probably bad)
- Whether the method ever returns null, or if not, what it returns if there is no value
- @throws tags for all declared exceptions, describing the circumstances they are thrown
- @throws tags for any likely undeclared exceptions
- @since tag for any interface, or interface method
- @see tags for other classes or methods that interact with the thing being documented in interesting ways, or for other ways to get the same information

Tip

If you say something in the doc comment, you should have a test that proves it's true.

Things to avoid

- Don't use the @author tag
- Don't use the @version tag

Package Level Comments

...would be nice, but every time I've attempted to add them, I've come up against how badly our packages are structured. I'd say not to bother right now.

Deprecation

So we don't keep stale methods around forever, we should always document when a method was deprecated. For example:
Logging Guidelines

The Purpose of Logging

Logging has three customers:

- The user (server administrator) wants to know if their server is running correctly
- Atlassian support wants evidence of possible problems
- Developers want to be able to trace code execution without attaching a debugger

When you write any code in Confluence, you should ask yourself what you would want to see, from the point of view of the above three people. If you were running a server, what would you want to be notified of? If you were handling a support case regarding some problem with the system, what information would you need? If you were tracing a bug in the code, what would you want to see logged?

Loggers

The current practice in Confluence is to create a `static final logger` called `log` (`lower-case in each class that needs to perform logging. This may need to be addressed in the future. You will find some old code still uses `Category.getInstance()` instead of `Logger.getLogger()`. Category is deprecated in newer versions of log4j, and should be phased out as you find it.

```java
private static final Logger log = Logger.getLogger(TheCurrentClass.class);
```

There is a special log called `startupLog` in `ConfluenceConfigurationListener`, which defaults to logging at `INFO` level, and is used to print out informational messages on system startup. Use this definition for startup messages:

```java
private final static Logger startupLog = Logger.getLogger("com.atlassian.confluence.lifecycle");
```

Log Levels

- **DEBUG** Fine-grained information about what is going on within the system.
- **INFO** Announcements about the normal operation of the system - scheduled jobs running, services starting and stopping, significant user-triggered processes
- **WARN** Any condition that, while not an error in itself, may indicate that the system is running sub-optimally
- **ERROR** A condition that indicates something has gone wrong with the system
- **FATAL** A condition that indicates something has gone wrong so badly that the system can not recover

Default Log Level

The standard Confluence log (level WARN) is a way for Confluence to communicate with the server administrator. Anything we log to this file will worry the administrator in some way. Logging at WARN level and higher should be reserved for situations that require some kind of attention from the server administrator, and for which corrective action is possible.

We should assume that any time Confluence logs a WARN level message or higher, the customer will create a support case, and will expect us to provide a solution that prevents that message from happening again.

Context

You can rarely put too much context in a log message. Don’t just say an operation failed. Say what operation you were attempting when it failed, what object you were trying to act on, and why. Remember to log the exception, so a stack-trace can be logged.

Bad:

```java
log.error("Unable to save page: " + exception.getMessage());
```

Better:
The Mapped Diagnostic Context

The log4j MDC allows you to add contextual information to a ThreadLocal, which is then included with subsequent log messages. This is a useful tool when you need to add the same contextual information to a lot of log messages.

For example, we currently use the MDC in the LoggingContextFilter to add the request URL and current user to the logging context for every web request.

Example usage:

```java
while (objectsToIndex.hasNext())
{
    Searchable obj = (Searchable) objectsToIndex.next();
    try
    {
        MDC.put("Indexing", obj.toString());
        index(obj);
    }
    finally
    {
        MDC.remove("Indexing");
    }
}
```

Logging Risks

Logging has the potential to introduce Heisenbugs into your code, because the act of turning logging on to look for an error changes the code-paths around where the error is occurring. For example, logging often calls `toString()` on the objects it wants to log information about. In turn, the `toString()` method of an object may have unexpected side-effects, for example causing some lazy-loaded Hibernate property to be loaded in from the database.

Also, make sure to check that an object can’t be null when calling a method on it. Especially when reporting errors, do go the extra mile to query for null, e.g. like this:

```java
if (previousPage!=null) {
    previousPageOutdatedId=previousPage.getOutdatedId();
}
```

instead of

```java
log.error("Unable to revert to previous page "+ previousPage.getOutdatedId());
```

Logging Performance

- Always wrap debug-level logging in `isDebugEnabled()` checks.
- Put any frequently-accessed info-level logging in an `isInfoEnabled()` check.
- Avoid logging inside a tight loop, and if you have to make sure it’s at the debug level.

Logging progress

It is absolutely vital that some kind of logging is done during a long running task. At least at the start and at the end of it. Usually, a loop will call a single operation very often. Make sure that - depending on how long a single call takes - you log each 10th, 100th, 1000th operation. If possible add the complete number of operations that will have to be performed, e.g. in the form " executing delete user (2000/5301)"

Migrating to Velocity 1.5

Confluence trunk development (2.8) will be based on Velocity 1.5. The migration to the latest version of Velocity brings with it some issues that Confluence developers need to be aware of.
Word tokens are no longer valid as the first argument to Velocimacros

In Velocity 1.4, the velocimacro syntax was changed to prevent the use of work tokens as the first argument to most directives (except for defining the macro itself). This makes the following, common webwork structure fail to parse in Velocity 1.4 and beyond.

This means that you must quote the first argument to make it a proper string.

For these directives to work correctly with the new syntax a patched version of Webwork 2.1 is also required. Confluence now depends on this custom version of Webwork 2.1.

Multi-line comments behave strangely in Velocimacros

Due to an apparent bug in Velocity 1.5, multi-line comments in Velocimacros can cause ParseExceptions. Multi-line macro comments have mainly been used in Confluence to control the output of extraneous whitespace during the rendering of a macro. To work around this issue a new trim() directive has been introduced that can be used to strip whitespace from macro rendering. This unfortunately introduces a slight overhead to rendering as whitespace must be trimmed in every execution at runtime rather than stripped by the lexer at template parsing time.

We'll be able to revert to the previous method once VELOCITY-537 is fixed and integrated, although it's arguable that the new directive makes for more maintainable macros.

Exceptions from method executions in macro parameters are no longer swallowed

Due to another bug in Velocity 1.3, exceptions that occur during a method execution in a macro parameter evaluation were swallowed silently; the return value of such executions was null. Velocity 1.5 contains a fix for this which means its likely that we are going to run into situations where pages which previously worked regardless of broken method calls are going to fail with a MethodInvocationException. There's only one correct solution here: fix the broken method calls as we find them.

Equality test operator is more strict

In previous versions of Velocity testing for equality using just a single = worked. This has been made stricter in Velocity 1.5; you must use == otherwise a ParseException will be thrown.

Backwards compatibility with Velocity templates used in existing themes and plugins

We realise that some of the changes that Velocity 1.5 brings to Confluence could cause annoying compatibility problems and lots of work for plugin maintainers, particularly the new Velocimacro syntax requirements. Confluence 2.8 will load all plugin templates using a special resource loader which will attempt to automatically fix loaded templates to work with the new Velocity engine (com.atlassian.confluence.util.velocity.Velocity13CompatibleResourceLoader). This does add some additional overhead to plugin loading (the template is adjusted once at load time and then cached) but it will ease the burden on plugin developers during this transitional period.

It is still a good idea for plugin authors to use the new Velocimacro syntax; updating your templates can be made easier by looking for the info messages logged by the resource loader whenever it finds incompatible syntax.
Spring Usage Guidelines

These are guidelines related to the development of Confluence. The guidelines mainly apply to Atlassian employees, but reading them should provide insight for third-party plugin developers as well, so we decided to make them public.

All new Spring component code should follow these guidelines. If you come across existing code that doesn't follow them, consider refactoring it to do so.

For an overview of how Spring is used in Confluence, see Spring IoC in Confluence.

General Rules

- For singleton components, prefer constructor-based injection with final fields for dependencies.
- If you have too many components to fit comfortably in a constructor, that's a sign the design is broken.
- Autowiring should only be used for transient, programatically constructed objects like actions and plugins. Never autowire anything that's defined in a config file.
- If a component is rarely used (i.e. the upgrade manager), consider giving it prototype scope instead of singleton.
- Avoid circular dependencies. If you see a circular dependency, ask yourself:
  - Can this problem be solved using events?
  - Can this problem be solved by having one party register a callback?

Transaction Management

- Transactions should be wrapped around the manager layer.
- Use the old-style Spring 1 transaction configuration syntax with explicit proxies - the Spring 2 pointcut syntax seems to slow down container startup (and thus test-running) by a factor of ten.

Profiling

- Managers and DAOs should be wrapped by the profiling interceptor
- If you're wondering whether a bean should be profiled or not, veer towards yes

Notes

Could we use some kind of funky XML Spring extension so we could declare a bean like this and have the extension apply the relevant interceptors?

```xml
<bean name="blahManager" class="com.example.BlahManager" atl:txn="defaultManagerTxn" atl:profile="yes"/>
```

Confluence Developer FAQ

This is a constantly updated FAQ listing questions and answers asked by people developing Confluence plugins and working with the Confluence code base in general. For general questions, check Confluence FAQ.

If you have a question, please ask it as a comment and someone from Atlassian will reply. Comment threads will gradually be merged back into this FAQ as needed. Please try to be as specific as possible with your questions.

Questions

- How does RENDERMODE work?
- Encrypting error messages in Sybase
- How do I get the information about Confluence such as version number, build number, build date?
- How do I make my attachments open in a new window or a tab?
- How do I tell if a user has permission to...?
- Disable "Remember my login on this computer"
RELATED TOPICS

Accessing Classes from Another Plugin

Disable "Remember my login on this computer"

At the moment there is no available option for disabling "Remember My Login on this computer" feature via the Admin console. However, there is a feature request available.
As a workaround, one can make modification to the velocity file `login.vm`. This would require a server restart nevertheless.

The steps required are as follow:

- Stop Confluence
- Go to your confluence install directory
- Locate the `<CONFLUENCE-INSTALL>/confluence/login.vm` file and make a back up copy
- Open the file. Locate the following code and comment it out.

```xml
<!-
<p>
<div class="steplabel" style="width: 150px;">
<input type="checkbox" name="os_cookie" id="os_cookie_id" value="true" tabindex="3"/>
</div>
<label for="os_cookie_id" accesskey="r">$action.getText("remember.accesskey")</label>
</p>
-->

- Save the file and restart Confluence
- Repeat the steps when you install a new version of Confluence

**Note:** The code above is already commented out.

### Disable Velocity Caching

When you are developing for Confluence, it is often useful to disable the caching of the velocity templates so that you don't have to restart the server to see velocity changes.

Perform the following modifications before starting the server, or restart it afterwards:

1. Edit your Velocity properties, which you will find in one of the following locations:
   - `./confluence/src/etc/java/velocity.properties`
   - `confluence/WEB-INF/classes/velocity.properties` for Confluence 2.5 and earlier, or
   - `confluence/WEB-INF/lib/confluence-[version].jar#velocity.properties` for Confluence 2.6 and later.
2. Set all the `.resource.loader.cache` values to `false`.
3. Set the `class.resource.loader.cache` to `false`. (If this entry does not exist, you can skip this step.)
4. Set `velocimacro.library.autoreload` to `true`. (Uncomment the line if necessary.)

Unfortunately, this does not apply to the macro library (macros.vm). Hence, a restart is essential.

### Enabling Developer Mode

Confluence's Developer Mode is a system property setting that tells Confluence to enable various debugging features that are not otherwise exposed to users. To enable Developer Mode, you should start Confluence with the following system property set:

```
-Dconfluence.devmode=true
```

If you are writing a Confluence extension and want to check if Developer Mode is active, you can call `ConfluenceActionSupport#isDevMode()` if you have an action available (`$action.devMode` in Velocity templates), or `Boolean.getBoolean(ConfluenceActionSupport.DEVMODE)` if you don't.

#### Developer Mode Features

Currently, enabling Developer Mode will activate the following features:

**Prior to Confluence 2.0**

- Developer Mode not available in these releases

**Confluence 2.0**

- The System Information page and 500 error page will contain an entry noting that Developer Mode is enabled
- The "view as HTML" button will be made available in the WYSIWYG rich-text editor

### Encrypting error messages in Sybase

Adaptive server messages

**How can I determine the context my macro is being rendered in?**
For Confluence 2.10 (remember that?), we converted the display of the Jira Issues Macro from using a static HTML table to using a table infused with jQuery goodness. Now we could add features that wouldn’t have been possible without JavaScript, like the ability to sort issues in the page without even reloading. That was pretty cool, but it also meant we had a new problem to deal with: macros can be rendered in places that can’t render JavaScript, such as in a feed reader or an email notification. In those cases, our beautifully redesigned macro would look something like a puddle of goo.

We thought about how to get around this new problem, and decided the best approach would be to make it possible for macros to find out if they are being rendered in an email or a feed, so they can display themselves appropriately. It was already possible for macros to find out if they are being rendered in a PDF document or several other contexts. In Confluence 2.10, we made it possible for macros to find out that they were being displayed in an email or feed, an addition to the previously defined contexts. Previously, macros being viewed in an email or feed reader would have just had the render type “display”, which is the default.

Now the Jira Issues Macro is able to render itself differently in display versus feed modes:

Okay, so how can you find out the current render context from within your macro? When creating a plugin that includes a macro module, you return the HTML that the macro will display from the execute() method of the macro class. One of the parameters to the execute() method, the one with type RenderContext, can be used to determine how the macro is being rendered.

Here’s a sample execute method from a macro that prints out the current render context type:

```java
public String execute(Map parameters, String body, RenderContext renderContext) {
    if (RenderContext.FEED.equals(renderContext.getOutputType()))
        return "FEED render type";
    else if (RenderContext.EMAIL.equals(renderContext.getOutputType()))
        return "EMAIL render type";
    else if (RenderContext.HTML_EXPORT.equals(renderContext.getOutputType()))
        return "HTML_EXPORT render type";
    else if (RenderContext.PREVIEW.equals(renderContext.getOutputType()))
        return "PREVIEW render type";
    else if (RenderContext.DISPLAY.equals(renderContext.getOutputType()))
        return "DISPLAY render type";
    else if (RenderContext.PDF.equals(renderContext.getOutputType()))
        return "PDF render type";
    else if (RenderContext.WORD.equals(renderContext.getOutputType()))
        return "WORD render type";
    else
        return "some other render type";
}
```

If you used this sample macro on a page you were editing (by first installing the plugin that contains it), you could visit the preview tab to see it output "PREVIEW render type". In the case of a more complex macro, you could, say, disable some UI elements when the RenderContext.PREVIEW.equals(renderContext.getOutputType()) check is true. Using these checks is exactly how the Jira Issues Macro decides whether to render itself using JavaScript or just stick with a basic HTML version.

Event Listener Plugins

**How does RENDERMODE work?**

Speaking generally, macros will want to do one of three things with their body:

1. Pass the body through wiki->html conversion, then do something to it like stick some more HTML around it. (i.e. {panel})
2. Do something to the body, then pass it through wiki->html conversion (I don’t really have an example of this)
3. Treat the body as data, not as wiki text. (i.e. {tasklist})

getBodyRenderMode() makes the first case above really easy, because the macro renderer will convert your body from wiki text to HTML before it’s passed to your macro’s execute() method. That way your macro has ready-made HTML delivered to it, and you don’t need to do anything.

If you return RenderMode.ALL from getBodyRenderMode(), then the body is rendered the same as a Confluence page. You can, however, return different values to only have a subset of renderings applied to your macro body: RenderMode.INLINE, for example, will ignore things like paragraphs, headers or blockquotes.

So, for example, the {color} macro returns RenderMode.INLINE, since you can only really use (color) inside a paragraph.

If you are doing macros of type 2 or 3, you’ll need to return RenderMode.NO_RENDER, which means the raw body is passed into your macro with no pre-processing. You can then do whatever you want with it (including grabbing the SubRenderer component and converting it to wiki text yourself).
Here's the relevant portion of the `MacroRendererComponent`, which does all the work, if Java code is more your thing:

```java
private void processMacro(String command, Macro macro, String body,
        Map params, RenderContext context,
        StringBuffer buffer)
{
    String renderedBody = body;
    try {
        if (TextUtils.stringSet(body) && macro.getBodyRenderMode() != null
                && !macro.getBodyRenderMode().renderNothing())
        {
            renderedBody = subRenderer.render(body, context, macro.getBodyRenderMode());
        }

        String macroResult = macro.execute(params, renderedBody, context);
        if (macro.getBodyRenderMode() == null)
        {
            buffer.append(macroResult);
        } else if (macro.isInline())
        {
            buffer.append(context.getRenderedContentStore().addInline(macroResult));
        } else
        {
            buffer.append(context.addRenderedContent(macroResult));
        }
    } catch (MacroException e)
    {
        log.info("Error formatting macro: " + command + ": " + e, e);
        buffer.append(makeMacroError(context, command + ": " + e.getMessage(), body));
    }
    catch (Throwable t)
    {
        log.error("Unexpected error formatting macro: " + command, t);
        buffer.append(makeMacroError(context, "Error formatting macro: " + command + ": " + t.toString(), body));
    }
}
```

How do l... find unused spaces

This page has been moved to the Administration section, and will be removed from here at some indeterminate point in the future.

Sometimes, you want to know what is not being used. It's great to know what's getting most attention, but what about stagnant pages, or even entire spaces that are no longer active?

While viewing space activity and the Global Statistics plugin can provide hints, they still doesn’t always provide enough detail. The simple way is to go directly to the database. We recommend DbVisualizer, and have basic instructions for connecting it to HSQLDB.

The following query identifies the last date on which content was modified in each space within a single Confluence instance:

```sql
SELECT spaces.spacename, MAX(content.lastmoddate) FROM content, spaces WHERE content.spaceid = spaces.spaceid GROUP BY spaces.spacename;
```

It returns a list of spacenames, and the last date and time at which any content was added or changed.

Alternatively, this one simply identifies spaces whose content hasn't changed since a specified date:

```sql
SELECT spaces.spacename FROM content, spaces WHERE content.spaceid = spaces.spaceid GROUP BY spaces.spacename HAVING MAX(content.lastmoddate) < '2006-10-10';
```

The result is a simple list of space names.
It's also possible to present the information in a wiki page, using the SQL plugin, which can be installed via the Plugin Repository. You'll also need to define a database Resource in conf/server.xml and conf/WEB-INF/web.xml, as described here. Having done so, you can use wiki markup code like the following, replacing confluenceDS with the name of your own local datasource:

```sql
SELECT spaces.spacename AS Space, MAX(content.lastmoddate) AS LastModified
FROM content, spaces
WHERE content.spaceid = spaces.spaceid
GROUP BY Space;
```

The Chart plugin can be used in combination with the SQL plugin to give more visually attractive results.

### How do I associate my own properties with a ContentEntityObject?

**How do I associate my own properties with a ContentEntityObject?**

You will need the ContentEntityManager (see how to retrieve it). This manager allows you to store and retrieve arbitrary String values associated with a ContentEntityObject.

Properties are stored as simple key/value pairs. We recommend that anyone writing a third-party plugin use the standard Java "reverse domain name" syntax to ensure their keys are unique. Keys may be no longer than 200 characters.

```java
// Set the property
contentPropertyManager.setText(page, "com.example.myProperty", "This is the value")
// Retrieve it
String myProperty = contentPropertyManager.getText(page, "com.example.myProperty")
```

getText and setText can store strings of arbitrary length (up to the size-limit for CLOBs in your database). There is also a getString and setString which is slightly more efficient, but limited to 255 characters per value.

### How do I autowire a component?

**How do I autowire a component?**

Most of the time, you don't have to. All plugins will have their 'primary' objects (The macro in a macro plugin, the XWork actions in an XWork plugin, the RPC handler in an RPC plugin and so on...) autowired.

If you want to write an arbitrary object that is autowired, but that is not any particular plugin type itself, write a Component Plugin Module. The added advantage of this is that Confluence will then autowire other plugins with the component you have just written.

If, however, you find you need to autowire an arbitrary object with Spring components, use bucket.util.ContainerManager

```java
bucket.container.ContainerManager.autowireComponent(myObject);
```

Where myObject is the object instance that you wish to be autowired.

### How do I configure Confluence to use GMail as the mail server

To configure Confluence to use Gmail to send emails, you will need to create a JNDI mail session and then have Confluence use it as per this document.

Please see Setup a mail session in standalone version for some guidelines.

1. Move activation-1.0.2.jar and mail-1.4.1.jar from /confluence/WEB-INF/lib to <tomcat-install>/common/lib (Tomcat 5.5) or <tomcat-install>/lib (Tomcat 6).
2. Paste the following code in confluence.xml or server.xml (substitute username and password):
3. Add java:comp/env/mail/Session to your JNDI mail configuration from Administration > Mail Servers.

**Note:** You may optionally add mail.debug="true" into the <Resource> to see logs generated by JavaMail.

### How do I convert wiki text to HTML?

How do I convert wiki text to HTML?

This depends on where you want to do it:

**In a macro...**

You will need the SubRenderer (see how to retrieve it).

The SubRenderer has two render methods: one that allows you to specify a specific RenderMode for the rendered content, and another that uses the current RenderMode from the RenderContext.

If you just want the body of your macro rendered, you can have this done for you by the macro subsystem by having your macro's getBodyRenderMode method return the appropriate RenderMode.

**In some other component...**

You will need the WikiStyleRenderer (see how to retrieve a component).

The WikiStyleRenderer has a convertWikiToHtml method that takes the wiki text you wish to convert, and a RenderContext. If you are converting the text in the context of some ContentEntityObject (for example within a page or blog post), then you can call contentEntityObject.toPageContext() to retrieve its RenderContext. Otherwise pass in a new PageContext().

### How do I disable RSS Feeds?

Confluence does not have an option to disable RSS feeds from the Administration Console and there is a discussion regarding this in CONF-10755. However there is a workaround on how to disable RSS via some simple modifications that this guide will show.

To disable RSS feeds in Confluence, you would need to disable createrssfeed.action and configurerssfeed.action properties. They are defined in xwork.xml, a configuration file that is zipped in one of the Confluence dependencies library files.

In this guide, we will be modifying global.vmd and configurerssfeed.vm and place a modified xwork.xml within your Confluence installation directory. A modified version of each of the file is accessible from the links below. As ruled at the steps below, you can place them in the corresponding directories where they belong. However, before applying the patch remember to backup your original files.

- configurerssfeed.vm
- global.vmd
- xwork.xml

And then follow these steps:

- Place global.vmd in "<confluence-install>/confluence/decorators/global.vmd. This newer velocity file will remove the RSS functionalities from Confluence dashboard.
- Place the customized xwork.xml in "<confluence-install>/confluence/WEB-INF/classes/xwork.xml". This file has removed the xwork action so an rss feed can't connect (you'll notice it's commented out):

```xml
<!--
<action name="createrssfeed" class="com.atlassian.confluence.spaces.actions.CreateRssFeedAction">
<interceptor-ref name="defaultStack"/>
</action>
-->  
```
- The attached configurerssfeed.vm file contains an explanation why RSS is disabled. Place it in "<confluence-install>/confluence/dashboard/configurerssfeed.vm. You can modify the message to suit your need.
In this patch, the changes in xwork.xml above will cause entering creatorsrssfeed.action or configurersrssfeed.action into URL leading to the error page defined in configurersrssfeed.vm.

To disable the RSS Feeds link in the Advanced section of spaces, you have to unjar the confluence-x.y.z.jar (where x.y.z is the version of Confluence that you are using) which is located in confluence-install/confluence/WEB-INF/lib/confluence-x.y.z.jar. If none of this makes any sense to you, please refer to this page: Editing Files within JAR Archives

The file you are looking for is plugins/space-advanced-sections.xml.

Remove the following block from this file:

```
 Lines 76-83

<web-item key="rss" name="Rss Feeds" section="system.space.advanced/subscribesection" weight="10">
  <label key="title.rss.feeds" />
  <link>/spaces/listrssfeeds.action?key=$generalUtil.urlEncode($helper.spaceKey)</link>
  <icon height="16" width="16">
    <link>/images/icons/feed-icon-16x16.png</link>
  </icon>
</web-item>
```

Re Jar this file and replace the current confluence-x.y.z.jar file. You will have to restart confluence to see the effects.

How do I display the Confluence System Classpath?

At times, you may see an error like this:

```
java.lang.NoSuchMethodError:
org.apache.commons.fileupload.servlet.ServletFileUpload.setSizeMax
```

**Cause:** The Java classpath has another module (jar) somewhere that overrides the one shipped with Confluence.

**Solution:**

1. Please run the following to list all modules available to the class loader:

   ![http://path-to-confluence/admin/classpath.action](http://path-to-confluence/admin/classpath.action)

2. Check for and resolve duplicate jars.

How do I find Confluence Performance Tests?

Since the 2.10 release, Performance tests can be found [here](#)

How do I find Confluence Test Suite?

All our Tests are stored inside the 'source release' you can download if you have a commercial licence from atlassian main site

When you expand the 'source', you can locate the following:

- unit and integration test
  ...confluence-project/confluence/src
- acceptance test
  ...confluence-project/src/test

How Do I find enabled and disabled plugins in the Database?

**Enabled Plugins**

Plugins from the repository, once installed are stored in table PLUGINDATA. They are enabled after install.

**Disabled Plugins**

All Plugins (bundled and from the repository) that have been disabled have an entry in table BANDANA where BANDANAKEY is plugin.manager.state.Map. For Example if the pagetree macro had been installed but is currently disabled would be reflected in BANDANAVALUE
How do I find information about lost attachments?

You may like to use the findattachments.jsp which should detect missing attachments. Simply copy it to confluence/admin/findattachments.jsp and access it at <confluence_base_url>/admin/findattachments.jsp

Below is an example of the result generated by http://<confluence_base_url>/admin/findattachments.jsp

Beginning search...
Missing attachment: <path>/attachments/3477/279/1, filename: Final-OdysseyCodingConventions.doc, filetype: Word Document

As you can see in the above example, the script will report:

Location of the attachment missing

Full Name of the attachment

File type recognised:
- PDF Document
- Image
- XML File
- HTML Document
- Text File
- Word Document
- Excel Spreadsheet
- PowerPoint Presentation
- Java Source File
- Zip Archive

How do I find the logged in user?

This can be retrieved easily from the com.atlassian.confluence.user.AuthenticatedUserThreadLocal class which will give you the current logged in user as a com.atlassian.user.User object.

```java
User user = AuthenticatedUserThreadLocal.getUser();
```

Should the user not be logged in the user object will be null.

How do I get a reference to a component?

Confluence's component system is powered by Spring, but we've done a lot of nice things to make it easier for developers to get their hands on a component at any time.

**Autowired Objects**

If your object is being autowired (for example another plugin module or an XWork action), the easiest way to access a component is to add a basic Java setter method.
For example, if you need a `SpaceManager` simply add the following setter method. This setter will be called when the object is created.

```java
public void setSpaceManager(SpaceManager spaceManager) {
    this.spaceManager = spaceManager;
}
```

You can also write your own components which are automatically injected into your plugins in the same way. See `Component Plugins` for more detail.

### Non-autowired Objects

If your object is not being autowired, you may need to retrieve the component explicitly. This is done via the `ContainerManager` like so:

```java
SpaceManager spaceManager = (SpaceManager) ContainerManager.getComponent("spaceManager");
```

### How do I get hold of the HttpServletRequest?

How do I get hold of the HttpServletRequest?

```java
HttpServletRequest request = ServletActionContext.getRequest();
if (request != null) {
    // do something here
}
```

You should always assume that `ServletActionContext.getRequest()` will return null. `ServletActionContext` is only populated if the request comes in through WebWork. There are a number of circumstances in which it will not be populated, either because a web request has come in through some other path, or because there was no web request in the first place:

- AJAX requests that come in via the DWR servlet
- SOAP/XML-RPC requests
- Scheduled tasks, including the sending of email notifications

Treat `ServletActionContext` as a bonus. If it's populated you can do neat things with it, but don't rely on it.

### How do I get my macro output exported to HTML and PDF?

How do I get my macro output exported to HTML and PDF?

This is only applies to Confluence 2.7 and higher.

```java
ExportDownloadResourceManager
```

Macros such as the chart macro may produce images, which should be included in HTML and PDF exports. This is now possible if macros delegate the responsibility of storing the output to Confluence.

The `ExportDownloadResourceManager` is responsible for managing the reading and writing of macro output. Confluence uses this manager to lookup/retrieve macro output for downloads and exports. Hence, if you would like your macro to support exports, it is required that you use this manager to retrieve the correct writer to write to.
Confluence 3.0 Documentation

ExportDownlaodResourceManager
/**
* Returns a DownloadResourceReader for reading the stored output of the previous execution of a
macro.
* Typically used by HTML and PDF export, macro content downloads.
*
* @param userName the user who is viewing the macro output. Must be the same as the user who
created the macro
* output with {@link #getResourceWriter(String, String, String)}, or an
UnauthorizedDownloadResourceException
* will be thrown.
* @param resourcePath the relative URL of the resource including the application context path.
For example,
* "/confluence/download/temp/chart1756.png". It must be the same path from the {@link
DownloadResourceWriter}.
* @throws UnauthorizedDownloadResourceException if the user requesting the macro output is
different to the user
* who created it
* @throws DownloadResourceNotFoundException if a stored macro output associated with this
resource path cannot be
* found
*/
public DownloadResourceReader getResourceReader(String userName, String resourcePath, Map
parameters)
throws UnauthorizedDownloadResourceException, DownloadResourceNotFoundException
/**
* Returns a DownloadResourceWriter for storing output of a macro in a temporary location.
* This should be typically called by macros that generate output such as images and would like
their
* output to be exported correctly.
*
* @param userName the user who is creating the macro output.
* @param prefix the prefix of the macro output's name
* @param suffix the suffix of the macro output
*/
public DownloadResourceWriter getResourceWriter(String userName, String prefix, String suffix)

The following is an example of how to retrieve the output stream for which you can use to write your macro output to.
public class ExampleMacro extends BaseMacro
{
private ExportDownloadResourceManager exportDownloadResourceManager;
public void setExportDownloadResourceManager(ExportDownloadResourceManager
exportDownloadResourceManager)
{
this.exportDownloadResourceManager = exportDownloadResourceManager;
}
public String execute(Map parameters, String body, RenderContext renderContext) throws
MacroException
{
// parse parameters and generate the output/image
....
// get the current user
User user = AuthenticatedUserThreadLocal.getUser();
String userName = user == null ? "" : user.getName();
// get the resource writer
DownloadResourceWriter writer = exportDownloadResourceManager.getResourceWriter(userName,
"example", "png");
OutputStream outputStream = writer.getStreamForWriting();
try
{

// write to the output stream
.....

}
finally
{
// close the output stream
if(outputStream != null)
outputStream.close();
}

return "<img src=\"" + writer.getResourcePath() + "/>";
}

1001

}


How do I get the base URL and ContextPath of a Confluence installation?

When you are writing Confluence plugins, sometimes you need to create an absolute URL, with the full “http://...” included. To do that, you need to determine what the URL path is up to the root of the Confluence web application.

Confluence attempts to guess the correct base URL for the site during setup. You can change it in the site’s General Configuration.

How do I determine the base URL and context path?

There are two ways of doing this. If you have a more recent version of Confluence, you can get it all in one spot. Older versions will require joining two separate string values.

Recent versions of Confluence

Recent versions of Confluence give the full path you need from one location.

First you need the SettingsManager object (see how to retrieve it), then call the following method:

```java
String baseUrl = settingsManager.getGlobalSettings().getBaseUrl();
```

Older versions of Confluence

Older versions of Confluence have what you need split into two parts, the base URL and the context path.

The base URL is the URL for the root of your Confluence site. For example, the base URL for this site is http://confluence.atlassian.com. If you have installed Confluence somewhere other than the root directory of the webserver, for example http://www.example.com/confluence, then your base URL would be http://www.example.com/confluence.

First you need the BootstrapManager (see how to retrieve it) then simply call the following method:

```java
String baseUrl = bootstrapManager.getBaseUrl();
```

To complete the URL, you will need to add the context path. The context path is the path to Confluence relative to the root directory of the webserver. For example, the context path for this site is an empty string, because it is deployed at the root. The context path for a Confluence instance deployed at http://www.example.com/confluence would be /confluence.

To get it, use:

```java
String contextPath = bootstrapManager.getWebAppContextPath();
```

To get the full path, just do this:

```java
String fullPath = baseUrl + contextPath;
```

In Confluence 2.0 and earlier the method was called bootstrapManager.getDomain(). The getDomain() method was deprecated in favour of getBaseUrl() in Confluence 2.1, because the latter name better describes the information it returns.

How do I get the information about Confluence such as version number, build number, build date?

Information about Confluence, such as the version number, build number and build date, can be retrieved from the GeneralUtil object.

You can use GeneralUtils public accessors to retrieve public static variables:

- versionNumber
- buildDate
- buildNumber

In Java

```java
String versionNumber = GeneralUtil.getVersionNumber();
```
String buildNumber = GeneralUtil.getBuildNumber();

String buildDate = GeneralUtil.getBuildDateString();

or

Date buildDate = GeneralUtil.getBuildDate();

In Velocity

$generalUtil.versionNumber
$generalUtil.buildNumber
$generalUtil.buildDateString

For instance, part of the Confluence footer is generated in the footer.vm file:

(Version: $generalUtil.versionNumber Build:$generalUtil.buildNumber $generalUtil.buildDateString)

In Wiki markup

User Macros can include the Velocity markup given above. For example, create a macro called 'version' with no body and the contents:

$generalUtil.versionNumber

You can use this user macro in a page like this:

Congratulation, you're running Confluence version {version}!

How do I get the location of the confluence.home directory?

How do I get the location of the confluence.home directory?

First you need the BootstrapManager (see how to retrieve it) then simply call the following method:

String confluenceHome = bootstrapManager.getConfluenceHome();

The BootstrapManager also has a getConFiguredConfluenceHome method. This method is used during system startup to determine the location of confluence.home from first principles. There is no reason for you to call this method: getConfluenceHome should be sufficient.

How do I load a resource from a plugin?

The recommended way to get resources from the classpath in Confluence is:

InputStream in = com.atlassian.core.util.ClassLoaderUtils.getResourceAsStream(filename, this);

ClassLoaderUtils tries a couple of different classloaders, something we've occasionally found necessary in some application servers.

How do I make my attachments open in a new window or a tab?

How do I make my attachments open in a new window/tab?

You need to add a TARGET = "_blank" to the <a href> HTML tag.
The `a` element used in HTML denotes an anchor which is a hypertext link. The `HREF` attribute specifies a hypertext link to another resource, such as an HTML document or a JPEG image. The `TARGET` attribute is used with frames to specify the frame in which the link should be rendered. If no frame with such a name exists, the link is rendered in a new window unless overridden by the user. Special frame names begin with an underscore. The frame used in this document is the `_blank` which renders the link in a new, unnamed window.

For example, by using the HTML code below, clicking on the link "a new window" will open the "newwindow.html" page in a new window:

```html
<A href="newwindow.html" _TARGET="_blank">a new window</A>
```

Open attachments listed for a Space

To open the attachments listed from the `Browse Space -> Attachments` tab, in a new window, the `Attachment(s)` file under your `<Confluence-install>` directory has to be modified. Below are the listed steps:

1. Locate the following block of code in the `listattachmentsforspace.vm` file:

   ```jsp
   foreach ($attachment in $pagedAttachments)
   <tr #alternateRowColors() id="attachment_$attachment.id">
   <td width="1%" nowrap valign="top"><a
   name="$generalUtil.urlEncode($attachment.content.realTitle)-attachment-$generalUtil.urlEncode($attachment.fileName)"#parse('/pages/includes/attachment_icon.vm')
   href="$req.contextPath$attachment.downloadPathWithoutVersion" >$attachment.fileName</a></td>
   <td width="1%" nowrap valign="top">$attachment.niceFileSize</td>
   <td width="1%" nowrap valign="top"><#usernameLink($attachment.creatorName)><#if ($attachment.creatorName!=$attachment.lastModifierName) ($action.getText('last.modified.by')#usernameLink($attachment.lastModifierName)) #end</td>
   <td width="1%" nowrap valign="top">$dateFormatter.format($attachment.lastModificationDate)</td>
   <td>#contentLink2 ($attachment.getContent() true false)</td>
   </tr>
   #end
   ```

2. In the line below:

   ```jsp
   <td width="1%" nowrap valign="top"><a
   name="$generalUtil.urlEncode($generalUtil.urlEncode($page.title))-attachment-$generalUtil.urlEncode($generalUtil.urlEncode($attachment.fileName))"#parse('/pages/includes/attachment_icon.vm')
   href="$generalUtil.htmlEncode($generalUtil.htmlEncode("${req.contextPath}${attachment.downloadPathWithoutVersion}")TARGET = "_blank")$attachment.fileName</a></td>
   ```

   add the parameter `TARGET = "_blank"` to the `<a href>` HTML tag, which will cause the URL specified in the `href` parameter to open in a new window or a new tag depending upon the option set in the browser. So the line above will be modified to:

   ```jsp
   <td width="1%" nowrap valign="top"><a
   name="$generalUtil.urlEncode($generalUtil.urlEncode($page.title))-attachment-$generalUtil.urlEncode($generalUtil.urlEncode($attachment.fileName))"#parse('/pages/includes/attachment_icon.vm')
   href="$req.contextPath$attachment.downloadPathWithoutVersion" TARGET = "_blank">$attachment.fileName</a></td>
   ```

Open attachments listed for a Page

To open the page attachments listed from the Page's `Attachment(s)` tab, in a new window, the `Attachment(s)` file under your `<Confluence-install>` directory has to be modified. Below are the listed steps:

1. Locate the following block of code in the `viewattachments.vm` file:

   ```jsp
   <td nowrap valign="top"><a
   name="$generalUtil.htmlEncode($generalUtil.htmlEncode($generalUtil.htmlEncode($page.title))-attachment-$generalUtil.htmlEncode('/pages/includes/attachment_icon.vm'))
   href="$generalUtil.htmlEncode($generalUtil.htmlEncode($page.title))-attachment-$generalUtil.htmlEncode($generalUtil.htmlEncode($attachment.downloadPathWithoutVersion))" TARGET = "_blank">$generalUtil.htmlEncode($attachment.fileName)</a></td>
   ```

2. In the line below:
1. add the parameter TARGET = "_blank" to the &lt;a&gt; HTML tag, which will cause the URL specified in the href parameter to open in a new window or a new tag depending upon the option set in the browser. So the line above will be modified to:

   &lt;a href="${req.contextPath}${attachment.downloadPathWithoutVersion}" TARGET = "_blank"&gt;$generalUtil.htmlEncode($attachment.fileName)&lt;/a&gt;

### How do I prevent my rendered wiki text from being surrounded by paragraph tags?

**How do I prevent my rendered wiki text from being surrounded by &lt;p&gt; tags?**

When wiki text is converted to HTML, the level of conversion is determined by the `RenderMode` set within the `RenderContext`. Understanding `RenderMode` is quite important, so you should familiarise yourself with the documentation linked above.

There are two render modes that are useful if you want to avoid the output being placed inside paragraph tags:

- **RenderMode.INLINE** will suppress the rendering of all block-level HTML elements, including paragraphs, blockquotes, tables and lists. Inline elements such as text decorations, links and images will still be rendered.
- **RenderMode.suppress(RenderMode.F_FIRST_PARA)** will render block-level elements as usual, but if the first such element is a paragraph, no paragraph tags will be drawn around it. This is useful if you're placing your output inside a &lt;div&gt;.

If you are writing a macro, you will also need to return `true` from your macro's `isInline` method.

### How do I tell if a user has permission to...?

**How do I tell if a user has permission to...?**

When you’re writing a Confluence plugin, it’s important to check that the user has permission to do the operations your plugin is performing. Confluence does not enforce security for you, it’s up to your code to perform these checks.

There are two places you might want to check permissions:

- **In Java Code**
- **In Velocity Templates**

#### In Java Code:

You will need:

1. the `User` object of the user whose permissions you want to check ([How do I find the logged in user?](#how-do-i-find-the-logged-in-user))
2. the `permissionManager` component from Spring ([How do I get a reference to a component?](#how-do-i-get-a-reference-to-a-component))

The `PermissionManager` has quite a few methods ([Javadoc](#)), but the most important are:
Simple Permissions

Generally you're going to be asking the question: "Does some user have permission to do something to some target?" For example: "Does BOB have permission to VIEW this PAGE?", "Does JANE have permission to REMOVE this ATTACHMENT?" These questions map to the hasPermission() method above.

The various values of "something" are all constants of the Permission class listed in this Javadoc. At the time this document was written, the permission 'verbs' are:

- Permission.VIEW
- Permission.EDIT
- Permission.EXPORT
- Permission.REMOVE
- Permission.SET_PERMISSIONS
- Permission.ADMINISTER

So to check if your user has permission to edit a particular page, the call is:

```java
permissionManager.hasPermission(myUser, Permission.EDIT, thePage)
```

For global permissions, the 'target object' is considered to be the Confluence application itself. There is a special target, PermissionManager.TARGET_APPLICATION that represents the application as a whole. So to check if someone is a global administrator, call:

```java
permissionManager.hasPermission(myUser, Permission.ADMINISTER,
PermissionManager.TARGET_APPLICATION)
```

Create Permissions

Checking if someone has the ability to create an object (page, blogpost, space, etc) is a little more complicated. Every object is created inside some other object. Comments and Attachments are created inside Pages or BlogPosts. Pages are created inside Spaces. And Spaces are created inside TARGET_APPLICATION.

So to check if someone can create something, the question is: "Does this user have permission to create this KIND OF OBJECT, in this CONTAINER?" In Java, kinds of objects are represented by their class, so to see if a user can create a comment inside a particular page, you'd call:

```java
permissionManager.hasCreatePermission(myUser, containingPage, Comment.class)
```
And to check if the user has permission to create spaces globally:

```java
permissionManager.asCreatePermission(myUser, PermissionManager.TARGET_APPLICATION, Space.class)
```

In Velocity Templates

While all of the above is very powerful, it's a bit complicated to deal with in a Velocity file. There is an object in the default velocity context called $permissionHelper which has a bunch of useful methods on it. All the methods do pretty much what you'd expect them to do, so I'll just link to the Javadoc:

http://www.atlassian.com/software/confluence/docs/api/latest/com/atlassian/confluence/security/PermissionHelper.html

And give a simple example:

```velocity
#if ($permissionHelper.canEdit($remoteUser, $action.page))
<b>You have Edit Permission for this Page</b>
#end
```

How do I use HTTPS for login only?

Instructions for enforcing the use of HTTPS for the login page, but falling back to HTTP for all other pages:

Once you have SSL working on tomcat, you need to make use of the urrewrite plugin that's included by default with Confluence. First, edit the filter-mapping entry in web.xml for urrewrite from this:

```xml
<filter-mapping>
  <filter-name>UrlRewriteFilter</filter-name>
  <url-pattern>/s/*</url-pattern>
</filter-mapping>
```

to this:

```xml
<filter-mapping>
  <filter-name>UrlRewriteFilter</filter-name>
  <url-pattern>/*</url-pattern>
</filter-mapping>
```

The next step is to edit urrewrite.xml to read like this, changing the hostname and port number to suit your own installation:

```xml
<?xml version="1.0" encoding="utf-8"?>
<!DOCTYPE urrewrite PUBLIC "-//tuckey.org//DTD Ur_rewrite 2.6//EN" "http://tuckey.org/res/dtds/ur_rewrite2.6.dtd">
<urrewrite>
  <rule>
    <from>/s/(.*)/_/([^?]*).*/</from>
    <run class="com.atlassian.plugin.servlet.ResourceDownloadUtils" method="addCachingHeaders" />
    <to type="forward">/$2</to>
  </rule>

  <rule>
    <from>/login.action</from>
    <condition type="scheme" operator="notequal">https</condition>
    <to type="redirect">http://localhost:8443/login.action</to>
  </rule>

  <rule>
    <from>/(.*)</from>
    <condition type="scheme" operator="equal">https</condition>
    <condition type="request-uri" operator="notequal">/login.action.*</condition>
    <condition type="request-uri" operator="notequal">/s/.*</condition>
    <to type="redirect">http://localhost:8080/$1</to>
  </rule>
</urrewrite>
```

HTTP Response Code Definitions

**HTTP Response Codes**

Below is a list of HTTP Response codes and their meaning.
This information was obtained from:

HTTP Version not supported

**HTTP Headers**

It would be useful to obtain information on HTTP response headers. If you are using Mozilla Firefox, you can download an 'add-ons' (extension) called LiveHTTPHeaders which will allow you to capture this information. If you are using Internet Explorer, you can use DebugBar instead.

**Live HTTP Headers Installation Instructions**

For Live HTTP Headers, please do the following:

1. Download and install the Plugin
2. Restart Firefox
3. Go to Tools in the menu bar and click on Live HTTP Headers. This will trigger the functionality.

Now try accessing the Confluence main page and all HTTP request headers, cookies descriptions (such as the seraph authentication 'seraph.os.cookie') will be logged in the pop-up window. Please save this information in a text file, use the 'Save All' option.

**DebugBar Installation Instructions**

Run the downloaded installation file. After installing the DebugBar, the toolbar should automatically display on the next IE startup. If not, you might need to show the toolbar in IE by clicking on View > Explorer Bar then select DebugBar

**I am trying to compile a plugin, but get an error about the target release**

When compiling plugins and using version 1.5 of the JDK, the following error may appear:

```
javac: target release 1.3 conflicts with default source release 1.5
```

**SOLUTION**

The solution is essentially to tell your compiler to target Java 1.3. How to do this will differ depending on what compiler you are using, but generally, something like this will work:

```
javac -target 1.3 <other options here>
```

If you are using Maven to build your project, try adding the following to your `project.properties` or `build.properties` file:

```
# Set the javac target to 1.3
maven.compile.target=1.3
maven.compile.source=1.3
```

If the solutions above do not resolve this issue and you are using an older version of Confluence, try the following approach:

Open the `src/etc/plugins/build.xml` file and in the line that looks similar to the following one, change its `target` parameter from "1.3" to "1.5":

```
<javac destdir="${library}/classes"    target="1.3" debug="${debug}" deprecation="false" optimize="false" failonerror="true">
```

Confluence Plugin Guide
[FAQ Home]

**What’s the easiest way to render a velocity template from Java code?**

Use VelocityUtils. You will need to provide VelocityUtils with the name of the template you want to render, and a map of parameters that will be made available within the template as $variables in velocity.
Confluence has a default set of objects for Confluence velocity templates. These are required for most Confluence velocity macros to work properly. To obtain this context, you should call `MacroUtils.defaultVelocityContext()`.

```java
// Create the Velocity Context
Map context = MacroUtils.defaultVelocityContext();
context.put("myCustomVar", customVar);
context.put("otherCustomVar", otherCustomVar);

// Render the Template
String result = VelocityUtils.getRenderedTemplate("/com/myplugin/templates/macro.vm", context);
```

**RELATED TOPICS**

Rendering Velocity templates in a macro

WoW Macro explanation

Macro Plugins

**What class should my macro extend?**

**X** What class should my macro extend?

It should extend `com.atlassian.renderer.v2.macro.BaseMacro`, **not** `com.atlassian.renderer.macro.BaseMacro`.

**What class should my XWork action plugin extend?**

**X** What class should my XWork action plugin extend?

WebWork actions must implement `com.opensymphony.xwork.Action`. However, we recommend you make your action extend `ConfluenceActionSupport`, which provides a number of helper methods and components that are useful when writing an Action that works within Confluence.

Other action base-classes can be found within Confluence, but we recommend you don't use them - the hierarchy of action classes in Confluence is over-complicated, and likely to be simplified in the future in a way that will break your plugins.

**What is Bandana? One form of Confluence Persistence**

Bandana is Atlassian's hierarchical data storage mechanism, it breaks objects into XML and stores them, to be retrieved later... uses xstream and a little hierarchical magic under the covers and has another strange Atlassian codename. It is one way to persist data inside your plugin. It is good for global config types of data.

It uses XStream to serialize Java strings (and objects?) to and from XML.

Examples:

The BandanaManager can be acquired via Confluence's (Spring's) dependency injection.

Data in this case is written to: `confluence-data-dir/config/confluence-global.bandana.xml`

Writing data:

```java
bandanaManager.setValue(new ConfluenceBandanaContext(), GmapsManager.GOOGLE_MAPS_API_KEY, updateApiKey);
```

Retrieving data:

```java
public String getGoogleApiKey()
{
    return (String) bandanaManager.getValue(new ConfluenceBandanaContext(),
        GmapsManager.GOOGLE_MAPS_API_KEY);
}
```

See also: Persistence in Confluence

**What is the best way to load a class or resource from a plugin?**

**X** What is the best way to load a resource from the classpath?

Because of the different ways that application servers deal with class-loading, just calling `this.getClass().getResourceAsStream()`
might not work the same everywhere Confluence is deployed. To help, we have a utility method that checks the various classloaders in a predictable order:

```java
InputStream in = com.atlassian.core.util.ClassLoaderUtils.getResourceAsStream(filename, this)
```

**Inside Plugins**

Because plugins may be dynamically loaded, each plugin may have its own classloader, separate from the main Confluence application. This makes loading resources like properties files from inside a plugin JAR a little tricky.

If the class from which you are loading the resource is in the same jar as the resource file itself (i.e. it's all part of the same plugin), you can use `ClassLoaderUtils` as above, and everything will work fine.

However, if you are trying to load the file from a different plugin, or from the main application code, you'll need an instance of the `pluginManager` from spring:

```java
InputStream in = pluginManager.getDynamicResourceAsStream(filename)
```

(That said, you must now ask yourself why you're loading an arbitrary resource from some other plugin? It seems like a really bad idea to me. If the plugin wants to export that resource to the rest of the application, it should provide some way of getting at it itself.)

**Within a Confluence macro, how do I retrieve the current ContentEntityObject?**

Within a Confluence macro, how do I retrieve the current ContentEntityObject?

You can retrieve the current `ContentEntityObject` (i.e. the content object this macro is a part of), as follows:

```java
public String execute(Map parameters, String body, RenderContext renderContext) throws MacroException {
    // retrieve a reference to the body object this macro is in
    if (!(renderContext instanceof PageContext)) {
        throw new MacroException("This macro can only be used in a page");
    }
    ContentEntityObject contentObject = ((PageContext)renderContext).getEntity();
    ...
```

Note that this method might return null if there is no current content object (for example if you are previewing a page that has not been added yet, or if a remote user is rendering a fragment of notation).

**Confluence Developer Forum**

The Confluence Developer Forum is a place for the discussion of extending and customising Confluence. There are two ways to join the discussion:

- Read the web-based forum
- Join the mailing-list

**Forum Guidelines**

The developer forum is set up for the discussion of:

- Confluence development: Plugins, themes or Confluence source customisation
- Confluence’s internal and remote APIs
- Automation of tasks in Confluence
- Announcement of new Confluence developer releases
- Announcement of new plugin releases
- Requests for plugins or customisation services
- Complaints that Atlassian have broken the plugin APIs again

The following are discouraged:

- Requests for support setting up or running Confluence should be directed to [http://support.atlassian.com](http://support.atlassian.com)
- Bug-reports should be submitted to [http://jira.atlassian.com](http://jira.atlassian.com) (If the bug is specific to plugin development or Confluence’s internal APIs, you can discuss it on the developer forum, but **PLEASE** submit a bug as well!)  
- Questions about using, running or administering Confluence should be directed to [The general Confluence forum](http://jira.atlassian.com)
- It’s OK to respond to requests for professional services on the forum, or to plug your business in plugin announcements or your signature, but please don’t just post advertisements.

**The Developer FAQ**

101
Some questions come up on the forum a lot. Make sure you've checked the Confluence Developer FAQ first.

About the Participants

When taking part in the forum, please keep in mind that Confluence licenses do not include a guaranteed level of developer support. The Confluence development team follows and contributes to the forum because it's important to us to have a healthy ecosystem of third-party developers, and because we love seeing the cool stuff that our customers and partners come up with. That said, we can't respond to every request, and developers are also expected to help themselves by reading the available documentation, the API, and occasionally even looking at the Confluence source-code.

Also keep in mind that a lot of the people on the list don't work for Atlassian at all, and are answering questions because they're nice people.

Confluence Plugin Guide

Looking for existing plugins? See the existing plugins and extensions written by the community in the Confluence Extensions space.

Confluence's plugin system allows users and developers to customise and extend Confluence.

A plugin is a bundle of code, resources and a special configuration file that can be dropped into a Confluence server to add new functionality, or change the behaviour of existing features.

- **Administrators** can drop plugins into their Confluence server to add new functionality to the system.
- **Developers** can write plugins for their own Confluence server, or share plugins with other Confluence users.

Some parts of Confluence are implemented entirely as plugins — for example, all macros in Confluence 1.3 and later are written as plugins, even those included with the system.

</tbody>
</table>

For example, the System plugins LeftNav theme plugin or the Clickr plugin will store data in WEB-INF/lib. Similarly for advanced-formatting macros.

Where are plugins run-time data stored

There is no distinct requirement where actual plugin's run-time data is stored. It is depended on the particular implementation of each plugin. The most common storage location would be: database, BANDANA, conf-home or other.

Plugins and Plugin Modules

Every plugin is made up of one or more plugin modules. A single plugin may do many things, while a plugin module represents a single function of the plugin.

For example, a theme plugin will consist of a colour-scheme module to define the theme's colours, a number of layout modules to define the site's page layouts, and a theme module to combine those pieces together into a single theme.

Some plugins, such as the macro packs that come with Confluence, are just a collection of unrelated modules that just happen to be packaged together. Other plugins, such as theme plugins, have modules that work together to provide some orchestrated functionality.

Writing Confluence Plugins

Looking for plugins? See the existing plugins and extensions written by the community in the Confluence Extensions space.

Confluence plugins provide a standard mechanism for extending Confluence. By adding plugins to Confluence you will be able to customise the site's look and feel, add new macros, event listeners and periodic tasks, and even introduce whole new features.

You can read the Confluence Plugin Guide for an overview of what plugins are. This document introduces Confluence plugins to developers who may want to write their own.

On this page:

- Anatomy of a Plugin
- Creating your Plugin Descriptor
- Creating a Basic Macro Plugin Skeleton
- Confluence Plugin Module Types
- Java Classes and Accessing Confluence Components
- Adding Plugin and Module Resources
- Adding a Configuration UI for your Plugin
- Ensuring Standard Page Decoration

Anatomy of a Plugin

A plugin is a single jar file that can be uploaded into Confluence. It consists of

- A plugin descriptor
- (Optional) Java classes
- (Optional) Resources

Plugins are composed of a series of modules, each of which defines a point at which the plugin interfaces with Confluence.

Creating your Plugin Descriptor

The plugin descriptor is a single XML file named atlassian-plugin.xml that tells the application all about the plugin and the modules contained within it. See Creating your Plugin Descriptor.

Creating a Basic Macro Plugin Skeleton

While even the most basic plugin involves quite a few directories and config files, creating a plugin skeleton is pretty easy and straightforward. We have prepared a Maven 2 template which does almost all the work for you. Please refer to the documentation in the Atlassian Developer Network for instructions on setting up your development environment and creating the most basic Confluence macro plugin. You can use its basic code skeleton to evolve your plugin into one of the categories described below.

Confluence Plugin Module Types

There are plenty of plugin types in Confluence. If you are new to plugin development in Confluence, we strongly suggest you start by writing a simple Macro Plugin. Macros are easy to write and give you visual feedback at once. Since the default plugin created by the Maven 2 template is a macro too, you can get started in almost no time at all.

Once you know your way around the Confluence API, you can evolve your plugin into something else, or of course create a new plugin and start from scratch. Each of the following plugin type descriptions assumes you have been able to create the basic plugin skeleton mentioned in the above paragraph.

See Confluence Plugin Module Types.

Java Classes and Accessing Confluence Components

When you upload a plugin JAR file into Confluence, all the Java classes contained within the JAR are available for your plugin to access. You can include as many classes as you like, and have them interact with each other. Because Confluence and plugins can export components for your plugin to use, it's important that you follow the Java package naming conventions to ensure your plugin's classes do not conflict with Confluence classes or with other plugins.

If you are writing a Java implementation of a plugin module, you will be interested in Accessing Confluence Components From Plugin Modules.
Adding Plugin and Module Resources

A 'resource' is a non-Java file that a plugin may need in order to operate. See Adding Plugin and Module Resources.

The simplest kind of resource, supported with all plugin module types, is of type download, which makes a resource available for download from the Confluence server at a particular URL. See Adding Plugin and Module Resources.

Adding a Configuration UI for your Plugin

A plugin for an Atlassian application can specify internal links within the application, to allow the user to configure options for the plugin. This is useful where your plugin requires configuration or user-specific settings to work. See Adding a Configuration UI for your Plugin.

Ensuring Standard Page Decoration

If you're writing a plugin that is intended for more than one Atlassian application, you can use the standard page decorators supported by Confluence. This allows your plugin to generate new web pages with consistent decoration by the host application across the Atlassian products. See Ensuring Standard Page Decoration in your Plugin UI.

Enabling TinyMCE Plugins

This documentation refers to a feature in the Confluence 3.1 release cycle. It will not work in Confluence 3.0 or before. Please check out our Milestone release notes to learn more about our milestone process for Confluence 3.1

TinyMCE is the wysiwyg editor we use in Confluence. You can now customise and enable TinyMCE plugins in Confluence by converting it as an Atlassian plugin. You simply need to define a plugin descriptor and provide a small snippet of javascript to configure your plugin.

Please note that this does not mean that all TinyMCE plugins are guaranteed to work in Confluence. Confluence is using a customised version of TinyMCE, so the plugins may not work 'out of the box' and could require some changes.

Defining the TinyMCE Plugin Resources

You will need to define the TinyMCE plugin resources (e.g. editor_plugin.js) in a web resource module with an added context of 'wysiwyg-editor'. Below is an example plugin descriptor for the TinyMCE Search & Replace plugin.

```xml
<atlassian-plugin name='TinyMCE Search Replace Plugin' key='tinymce.searchreplace.plugin'>
  ...
  <resource name="searchreplace/" type="download" location="searchreplace/"/>
  ...
  <web-resource name='TinyMCE Search Replace Web Resources' key='tinymce-searchreplace-resources'>
    <resource name="searchreplace.js" type="download" location="searchreplace/editor_plugin.js"/>
    <resource name="searchreplace-adapter.js" type="download" location="searchreplace/confluence-adapter.js"/>
    <context>wysiwyg-editor</context>
  </web-resource>
</atlassian-plugin>
```

Configuring TinyMCE Plugin Settings

To enable the TinyMCE plugin, you will need to configure the settings object that is typically passed to TinyMCE's init() method. To do this, simply add some javascript to register your configuration logic with AJS.Editor.Adapter.addTinyMcePluginInit. The following code enables the search/replace plugin and adds the search and replace buttons to the second row of the toolbar.
Confluence 3.0 Documentation

Converting a Plugin to Plugin Framework 2

Confluence 2.10 and later includes a new plugin framework is based on OSGi and Spring Dynamic Modules. The new plugin framework has all the advantages of OSGi, plus it will be included into all Atlassian products. This means that writing plugins for different products would be more consistent and porting the same plugin to different Atlassian applications will require fewer changes than it did in the past. For the full documentation of the Atlassian Plugin Framework 2, refer to the Plugin Framework Documentation.

Plugins that were written for the old framework will continue to work, but to leverage the new functionality you will need to convert your plugin to the new framework. This page describes how to migrate an existing plugin to the new Confluence plugin framework.

1. Set your plugin 'plugins-version' flag to version 2
2. Check that packages used by your plugin are available to OSGi plugins
   - 2.1 Rely on automatic package imports
   - 2.2 Customise package imports and exports with a bundle manifest
3. Check that components used by your plugin are available to OSGi plugins
   - 3.1 Specify qualifiers on ambiguous Spring dependencies
   - 3.2 Expose your plugin components to other plugins
   - 3.3 Import components exposed by other plugins
4. Advanced configuration with Spring configuration files
5. Confluence API limitations

RELATED TOPICS

1. Set your plugin 'plugins-version' flag to version 2

As described in the documentation there are two types of plugins in the Atlassian Plugin Framework 2:

- **Version 1** — These may be static (deployed in WEB-INF/lib) or dynamic (via the web UI, only in Confluence) and should work the same as they did in version 1 of the Atlassian Plugin Framework. The capabilities and features available to version 1 plugins vary significantly across products.
- **Version 2** — These plugins are dynamically deployed on an internal OSGi container to provide a consistent set of OSGi features and behaviours, regardless of the application the plugin is running on. Version 2 plugins have to be specifically declared as such, using the `plugins-version="2"` attribute in `atlassian-plugin.xml`.

So the first step of migration is to make your plugin a Version 2 plugin by setting `plugins-version="2"` attribute in `atlassian-plugin.xml`:

```
<atlassian-plugin name="plugin name" key="plugin key" enabled="true" plugins-version="2">
```

For the remainder of this document, Version 2 plugin and OSGi plugin should be considered synonymous.

2. Check that packages used by your plugin are available to OSGi plugins

OSGi plugins — plugins with 'plugins-version' set to 2 — are subject to certain restrictions. In particular, an OSGi plugin can access only those external classes that Confluence (or other plugins) explicitly expose. This means that you can no longer assume that all classes on the Confluence classpath will be accessible to your plugin.

Refer to the list of packages that Confluence 2.10 exposes, and ensure that all classes used by your plugin are covered by this list. The list of packages should be sufficient to access all the functionality of Confluence from within your plugin.

However, many of the third party packages that ship with Confluence are not exported. If your plugin needs any of these libraries, you will need to package them within the plugin. This has been done to provide better compatibility for plugins if Confluence upgrades those libraries in the future (eg. API incompatibilities that require code changes). The easiest way to package dependencies with your plugin is to use the Maven 2 Plugin Development Kit.

It is very important to ensure that plugin code does not depend on packages that are not exposed, as the problem will only manifest itself during runtime.

2.1 Rely on automatic package imports

OSGi plugins have their required packages imported transparently. You do not need to do anything to have required packages imported, but it may help to understand how this works.

Normally, an OSGi bundle needs to explicitly import all packages it needs. To work around this requirement, the plugin framework generates the list of required packages by scanning the class files inside your plugin and determining which packages they use. Once this list of

```
AJSEditor.Adapter.addTinyMcePluginInit(function(settings) {
    settings.plugins += ",searchreplace";
    settings.theme_advanced_buttons2 += ",search,replace";
});
```
packages is determined, the plugin system generates an OSGi manifest and inserts it into your plugin prior to loading it into the OSGi container. For more information, refer to OSGi Basics and how OSGI bundles are generated.

### 2.2 Customise package imports and exports with a bundle manifest

If you want to have a full control over what packages are imported by your plugin you can package the plugin as an OSGi bundle. To do this, you need to specify all necessary entries in a Manifest file inside your plugin JAR file. Using the Bundle Plugin for Maven makes the process of generating a valid OSGi manifest much simpler.

You might also want to configure a bundle manifest yourself if you want expose a set of packages as being exported from your plugin.

### 3. Check that components used by your plugin are available to OSGi plugins

The other important restriction for OSGi plugins is that they are only allowed to access those Spring components that are explicitly exposed by Confluence or other plugins. You can find the list of all components that are available to OSGi plugins under http://<baseURL>/admin/pluginexports.action. In this list, each Spring component is listed against the interfaces that it provides. In OSGi, every component must specify the interfaces it provides.

As with the exposed packages, the list of components attempts to cover all Confluence functionality but not to expose all the internals of the application. If your plugin uses the beans that are not exposed you should be able to find an exposed bean that provides the same functionality. As with the packages, this list is intentionally limited to try to improve plugin compatibility across releases of Confluence.

It is very important to ensure that plugin code does not depend on beans that are not exposed, as the problem will only manifest itself during runtime. The easiest way to ensure that there are no dependencies on beans which are not exposed is to use constructor injection. Using constructor injection will ensure that the plugin fails during the loading if any of the dependencies are not satisfied.

> As OSGi plugin components live in their own Spring context separate from Confluence's Spring container, you cannot use `ContainerManager.getComponent()` to retrieve your own plugin components (see PLUG-280)

#### 3.1 Specify qualifiers on ambiguous Spring dependencies

In some cases, Confluence exposes more than one bean under the same interface. When this happens, Spring can't determine exactly which bean to use to satisfy a dependency on that interface. For example, there are two exposed beans that implement the PluginController interface. Spring will fail to inject the right dependency unless you provide a Spring `@Qualifier` annotation.

```java
// Confluence has two beans that implement PluginController, so we add a qualifier to specify
// which one we want
public void setPluginController(@Qualifier("pluginController") PluginController pluginController) {
    this.pluginController = pluginController;
}
```

#### 3.2 Expose your plugin components to other plugins

In order to make a component in your plugin available to other plugins you can simply add the `public="true"` attribute to the component in your plugin descriptor file. You will need to specify one or more interfaces under which this bean will be exposed.

```xml
<component key="pluginScheduler" class="com.atlassian.sal.core.scheduling.TimerPluginScheduler"
    public="true">
    <interface>com.atlassian.sal.api.scheduling.PluginScheduler</interface>
</component>
```

#### 3.3 Import components exposed by other plugins

Components that are exposed by other plugins are treated a little differently to beans that are exposed by Confluence itself. Your plugin needs to specifically import components which come from other plugins. To do this, include a `<component-import>` tag inside `atlassian-plugin.xml` file.

```xml
<component-import key="loc" interface="com.atlassian.sal.api.license.LicenseHandler" />
```

You will also need to ensure that the component `class` is imported, which usually happens transparently.

### 4. Advanced configuration with Spring configuration files

The new plugin framework provides the ability to create plugin components using complete Spring configuration files. If you provide Spring Dynamic Modules (Spring DM) configuration files in META-INF/spring/, these will be loaded into your plugin OSGi bundle by the Spring DM loader. Using this option for configuration provides you with a lot of flexibility about how your plugin components are created and managed.
To include a Spring configuration file, ensure it is included in the META-INF/spring/ directory inside your plugin JAR file. All files matching *.xml inside this directory will be loaded as Spring configuration files when your plugin is loaded. For more details on Spring configuration, see the Spring documentation.

5. Confluence API limitations

- As mentioned above, you cannot use `ContainerManager.getComponent()` to retrieve your own plugin components. Instead, you should use dependency injection.
- `VelocityUtil.getRenderedTemplate()` uses Confluence’s Class loader. Therefore, you cannot use it to access your plugin's templates. See CONF-14459 for a workaround.

Packages available to OSGi plugins

Below are the Java packages exposed by Confluence 2.10. All of them, along with their sub-packages, are available to OSGi plugins running in the Atlassian Plugin Framework 2.2.

- com.atlassian*
- com.sun*
- com.thoughtworks.xstream*
- bucket*
- net.sf.cglib*
- net.sf.hibernate*
- com.opensymphony.*
- org.apache.*
- org.xml.*
- javax.*
- org.w3c.*
- org.dom4j.*
- org.quartz.*
- org.bouncycastle*

Inside the application, this list is configured as a parameter to the packageScanningConfiguration component in the pluginServiceContext.xml file. The XML file is in the services folder within the confluence/WEB-INF/lib/confluence-2.10.x.jar.

Writing Confluence Plugins

Creating your Plugin Descriptor

On this page:
Purpose of a Plugin Descriptor

When developing a plugin for an Atlassian application such as Confluence or JIRA, you need to create a 'plugin descriptor' for your plugin. The plugin descriptor is an XML file that tells the application all about the plugin and the modules contained within it. The descriptor must be a single file named `atlassian-plugin.xml` and must be located at the root of the plugin's jar file.

Example of a Plugin Descriptor

Here is a sample plugin descriptor:

```xml
<!-- Every plugin must have a key, which identifies the plugin uniquely to the system -->
<!-- and a name, which is used to display the plugin in menus. -->
<atlassian-plugin key="com.atlassian.confluence.plugins.example" name="Example Plugin" plugins-version="2">

<!-- The plugin info block allows you to provide more information about your plugin -->
<plugin-info>
  <description>
    A sample plugin for demonstrating the file format.
  </description>
  <!-- This version is displayed in the application's Plugin Manager. -->
  <version>1.0</version>
  <!-- The versions of the application this plugin is compatible with -->
  <application-version min="1.3" max="1.3"/>
  <vendor name="Atlassian Software Systems Pty Ltd" url="http://www.atlassian.com/"/>
  <!-- The location of any plugin configuration (optional) -->
  <param name="configure.url">/admin/plugins/example/configurePlugin.action</param>
  <!-- Specifically declare bundle instructions (optional) -->
  <bundle-instructions>
    <Export-Package>my.external.pkg</Export-Package>
    <Import-Package>com.mylibrary,*;resolution=optional</Import-Package>
  </bundle-instructions>
</plugin-info>

<!-- Here is where you define your modules. The code you use -->
<!-- to define a module depends on the module itself. This is just -->
<!-- a sample, which will not load if installed into Confluence -->
<example key="module1" name="Example Module" class="com.atlassian.confluence.plugins.example.ExampleModule">
  <!-- Modules must have a key that is unique within the plugin, a name -->
  <!-- and an implementing class. -->
  <description>An example module</description>
</example>
</atlassian-plugin>
```

Contents of the Plugin Descriptor

Below is a description of the plugin information provided in the descriptor XML file.

**atlassian-plugin element**

This is the root element for your plugin descriptor. For example, the plugin descriptor file should have this structure:
Confluence 3.0 Documentation

Attribute Description

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>Each plugin has a plugin key which must be unique to the plugin. We suggest using the Java convention of reversing your domain name in order to ensure your key is unique. The plugin key must be defined in the plugin descriptor. When you call the plugin via a macro in Wiki Markup, you can use any capitalisation, e.g. <code>{module1}</code> or <code>{Module1}</code>. Within the plugin, each module has a module key. Refer to the information on module types for information about the module key.</td>
</tr>
<tr>
<td>name</td>
<td>This is a human-readable name, used for display in menus within the application.</td>
</tr>
<tr>
<td>state</td>
<td>To disable the entire plugin by default, specify <code>&lt;atlassian-plugin state=&quot;disabled&quot;/&gt;</code>.</td>
</tr>
<tr>
<td>plugins-version</td>
<td>To create an OSGi plugin, use <code>plugins-version=&quot;2&quot;</code>. The attribute <code>pluginsVersion</code> is still supported but has been deprecated since version 2.1 of the plugin framework.</td>
</tr>
</tbody>
</table>

**plugin-info element**

This element contains plugin information displayed by the application for administrators, plugin parameters and OSGi bundle instructions. Its parent element is `<atlassian-plugin>`, and it supports several nested elements.

<table>
<thead>
<tr>
<th>Nested element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;description&gt;</code></td>
<td>A human-readable description of your plugin.</td>
</tr>
<tr>
<td><code>&lt;version&gt;</code></td>
<td>The version of your plugin. This number is displayed in the application's plugin manager.</td>
</tr>
<tr>
<td><code>&lt;application-version&gt;</code></td>
<td>Supply the versions of the application that will support your plugin.</td>
</tr>
<tr>
<td><code>&lt;vendor&gt;</code></td>
<td>Supply information about the developer of the plugin.</td>
</tr>
<tr>
<td><code>&lt;param&gt;</code></td>
<td>Supply parameter values if required by your plugin.</td>
</tr>
<tr>
<td><code>&lt;bundle-instructions&gt;</code></td>
<td>Declare plugin dependencies and shorten your export package lists by specifying OSGi bundle instructions directly in the plugin XML (OSGi plugins only).</td>
</tr>
</tbody>
</table>

These nested elements are described in more detail below.

**description element**

The body of this element is a description of your plugin. Its parent element is `<plugin-info>`.

```
<atlassian-plugin ...>
  <plugin-info>
    <!-- ... -->
    <description>New macros for integration with Acme Corp. web services</description>
  </plugin-info>
</atlassian-plugin>
```

**version element**

The body of this element is the current version of your plugin. Its parent element is `<plugin-info>`.

Plugin versions are sometimes compared within an application to determine the newer version, particularly when performing automated upgrades. Versions are compared by splitting the version number into components and comparing them numerically first and alphabetically second.

Following are some sample version numbers in ascending order: 0.99, 1.0, 1.0.1-alpha, 1.0.1-beta, 1.0.1-beta2, 1.0.1, 1.0.1.0, 1.1, 1.2, 1.10, 2.0.
**application-version element**

*Deprecated since Atlassian Plugin Framework 2.2*

Describe which versions of the host application are compatible with this plugin. Enforcement of this property varies between applications: some applications strictly enforce compatibility, while others ignore the value.

Its parent element is `<plugin-info>`.

<table>
<thead>
<tr>
<th>Attribute name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>min</td>
<td>This is the lowest version of the application which your plugin is compatible with.</td>
</tr>
<tr>
<td>max</td>
<td>This is the highest version of the application which your plugin is compatible with.</td>
</tr>
</tbody>
</table>

**vendor element**

The vendor of the plugin. Provides a link in the plugin administration screens.

Its parent element is `<plugin-info>`.

<table>
<thead>
<tr>
<th>Attribute name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Supply your name or the name of the company you work for.</td>
</tr>
<tr>
<td>url</td>
<td>Supply a web site address.</td>
</tr>
</tbody>
</table>

**param element**

Arbitrary parameters for a plugin. These can be nested in many other elements. Attribute 'name' gives the name of the parameter. The body of the element is its value.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the parameter.</td>
</tr>
<tr>
<td>(body)</td>
<td>The value of the parameter.</td>
</tr>
</tbody>
</table>

One commonly used parameter is the URL for your plugin's configuration screen. Its parent element is `<plugin-info>`. Below is an example.
bundle-instructions element

This element allows you to declare plugin dependencies and shorten your export package lists by specifying OSGi bundle instructions directly in the plugin XML. The element's parent element is <plugin-info>.

As seen in the above example, the bundle-instructions element allows child elements, including:

- <Export-Package>
- <Import-Package>

The Atlassian Plugin Framework uses the bnd tool to generate OSGi bundles. This tool is available as the Bundle Plugin for Maven.

For details of the bnd directives, please refer to the bnd documentation.

Elements Describing Plugin Modules

In the rest of the descriptor XML file, you will define any modules that make up your plugin. Please refer to the list of module types for more information.

<tr>
<td>colour-scheme</td>
<td>1.3</td>
<td>Theme Plugins</td>
<td>A colour-scheme for a theme</td>
</tr>
<tr>
<td>component</td>
<td>2.10</td>
<td>Component Plugins</td>
<td>Adds components to Confluence's component system. This is the newer and</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>recommended version of the component module type.</td>
</tr>
<tr>
<td>Component Type</td>
<td>Version</td>
<td>Module Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>---------</td>
<td>-------------</td>
<td>-------------</td>
</tr>
<tr>
<td>component</td>
<td>1.4</td>
<td>Component Plugins - Old Style</td>
<td>Adds components to Confluence's component system. This is the earlier version of the component module type.</td>
</tr>
<tr>
<td>component-import</td>
<td>2.10</td>
<td>Component Import Plugins</td>
<td>Accesses Java components shared by other plugins.</td>
</tr>
<tr>
<td>decorator</td>
<td>2.5</td>
<td>Decorator Plugins</td>
<td>Adds decorators without using a Theme Plugin</td>
</tr>
<tr>
<td>extractor</td>
<td>1.4</td>
<td>Extractor Plugins</td>
<td>Adds information to the Confluence search index</td>
</tr>
<tr>
<td>editor</td>
<td>2.5</td>
<td>Editor Plugins</td>
<td>Adds a Wysiwyg editor to the Confluence edit page</td>
</tr>
<tr>
<td>job</td>
<td>2.2</td>
<td>Job Plugins</td>
<td>Adds repeatable jobs to Confluence</td>
</tr>
<tr>
<td>language</td>
<td>2.2</td>
<td>Language Pack Plugins</td>
<td>Adds language translations to Confluence</td>
</tr>
<tr>
<td>layout</td>
<td>1.3</td>
<td>Theme Plugins</td>
<td>A layout (decorator) definition for a theme</td>
</tr>
<tr>
<td>lifecycle</td>
<td>2.3</td>
<td>Lifecycle Plugins</td>
<td>Schedule tasks to be run on application startup and shutdown</td>
</tr>
<tr>
<td>listener</td>
<td>1.4</td>
<td>Event Listener Plugins</td>
<td>A component that can respond to events occurring in the Confluence server</td>
</tr>
<tr>
<td>macro</td>
<td>1.3</td>
<td>Macro Plugins</td>
<td>A macro used in wiki to HTML conversions (e.g. {color}). Outputs HTML that can be embedded in a page or layout. Can retrieve user, page and space info, or external content (e.g. RSS)</td>
</tr>
<tr>
<td>module-type</td>
<td>2.10</td>
<td>Module Type Plugins</td>
<td>Dynamically adds new plugin module types to the plugin framework, generally building on other plugin modules.</td>
</tr>
<tr>
<td>path-converter</td>
<td>2.8</td>
<td>Path Converter Plugins</td>
<td>Allows you to install custom URL schemes as a part of your plugin, i.e. you can have 'pretty' URLs.</td>
</tr>
<tr>
<td>rpc-soap</td>
<td>1.4</td>
<td>RPC Plugins</td>
<td>Deploys a SOAP service within Confluence</td>
</tr>
<tr>
<td>rpc-xmlrpc</td>
<td>1.4</td>
<td>RPC Plugins</td>
<td>Deploys an XML-RPC service within Confluence</td>
</tr>
<tr>
<td>servlet</td>
<td>1.4</td>
<td>Servlet Plugins</td>
<td>A standard Java servlet deployed within a Confluence plugin</td>
</tr>
<tr>
<td>servlet-context-listener</td>
<td>2.10</td>
<td>Servlet Context Listener Plugins</td>
<td>Deploys Java Servlet context listeners as a part of your plugin.</td>
</tr>
<tr>
<td>servlet-context-param</td>
<td>2.10</td>
<td>Servlet Context Parameter Plugins</td>
<td>Sets parameters in the Java Servlet context shared by your plugin's servlets, filters, and listeners.</td>
</tr>
<tr>
<td>servlet-filter</td>
<td>2.10</td>
<td>Servlet Filter Plugins</td>
<td>Deploys Java Servlet filters as a part of your plugin, specifying the location and ordering of your filter.</td>
</tr>
<tr>
<td>spring</td>
<td>2.2</td>
<td>Spring Component Plugins - Old Style</td>
<td>Add a Spring component. Unlike component plugins these allow the use of full Spring configuration XML</td>
</tr>
<tr>
<td>theme</td>
<td>1.3</td>
<td>Theme Plugins - Old Style</td>
<td>A custom look-and-feel for a Confluence site or space</td>
</tr>
<tr>
<td>trigger</td>
<td>2.2</td>
<td>Trigger Plugins</td>
<td>Adds triggers which schedule jobs</td>
</tr>
<tr>
<td>usermacro</td>
<td>2.3</td>
<td>User Macro Plugins</td>
<td>Allows a simple macro to be created in the plugin XML file, with no Java coding necessary</td>
</tr>
<tr>
<td>velocity-context-item</td>
<td>1.4</td>
<td>Velocity Context Plugins</td>
<td>Adds helper objects to Confluence's Velocity context</td>
</tr>
<tr>
<td>web-item</td>
<td>2.2</td>
<td>Web UI Plugins</td>
<td>Adds links or tabs to the Confluence UI</td>
</tr>
<tr>
<td>web-resource</td>
<td>2.8</td>
<td>including Javascript and CSS resources</td>
<td>Allows you to include Javascript and CSS resources</td>
</tr>
<tr>
<td>web-section</td>
<td>2.2</td>
<td>Web UI Plugins</td>
<td>Adds sections of links to the Confluence UI</td>
</tr>
<tr>

Code Formatting Plugins

Code formatting plugin modules are available in Confluence 2.2 and later versions

Code formatting plugin modules allow you to add new languages to the (code) macro. Whenever the code macro is invoked, the macro checks the 'language' parameter against the languages supported by the available formatting plugins, and uses that plugin to format the source code.

- For more information about plugins in general, read Confluence Plugin Guide.
- To learn how to install and configure plugins (including macros), read Installing and Configuring Plugins Manually.
- For an introduction to writing your own plugins, read Writing Confluence Plugins

Here is an example file containing a single code formatter:

```xml
<atlassian-plugin name="My Formatter" key="confluence.extra.formatters">
  <codeformatter name="ruby" key="ruby" class="com.example.confluence.formatters.RubyFormatter">
    <description>Code formatter for the Ruby programming language</description>
  </codeformatter>
</atlassian-plugin>
```

- the class attribute defines the class that will be added to the available formatters. This class must implement com.atlassian.renderer.v2.macro.code.SourceCodeFormatter

The SourceCodeFormatter Interface

All code formatters must implement the following simple interface:

```java
package com.atlassian.renderer.v2.macro.code;

/**<p>Strategy for converting a block of source code into pretty-printed HTML. SourceCodeFormatters MUST be forgiving: they will be dealing with user-supplied input, so they can't afford to blow up on bad data.</p>*/
public interface SourceCodeFormatter {
  /**
   * Inform the CodeMacro which languages this formatter supports. So if someone writes [code:java], then only the formatter that returns "java" from this method will be used to format it.
   * @return an array of languages that this formatter supports
   */
  String[] getSupportedLanguages();

  /**
   * Convert source code into HTML.
   * @param code the source code as a string
   * @param language the programming language that it is believed this code is written in
   * @return the source code formatted as HTML
   */
  String format(String code, String language);
}
```

Formatter Priority

There is no concept of priority for formatters. If two formatters are installed and both return the same value from getSupportedLanguages(), one will be selected pretty much at random. If you want to avoid this behaviour, deactivate formatters that you no longer want to use.

Component Import Plugins

On this page:

- Purpose of this Module Type
- Configuration
  - Attributes
  - Elements
- Example
Notes

Purpose of this Module Type

Component Import plugin modules allow you to access Java components shared by other plugins, even if the component is upgraded at runtime.

Configuration

The root element for the Component Import plugin module is `component-import`. It allows the following attributes and child elements for configuration:

Attributes

<table>
<thead>
<tr>
<th>Name</th>
<th>Required</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>class</td>
<td></td>
<td>The class which implements this plugin module. The class you need to provide depends on the module type. For example, Confluence theme, layout and colour-scheme modules can use classes already provided in Confluence. So you can write a theme-plugin without any Java code. But for macro and listener modules you need to create your own implementing class and include it in your plugin.</td>
<td></td>
</tr>
<tr>
<td>disabled</td>
<td></td>
<td>Indicate whether the plugin module should be disabled by default (value='true') or enabled by default (value='false').</td>
<td>false</td>
</tr>
<tr>
<td>i18n-name-key</td>
<td></td>
<td>The localisation key for the human-readable name of the plugin module.</td>
<td>false</td>
</tr>
<tr>
<td>interface</td>
<td></td>
<td>The Java interface of the component to import. This attribute is only required if the interface elements are not used.</td>
<td>N/A</td>
</tr>
<tr>
<td>key</td>
<td>✓</td>
<td>The identifier of the plugin module. This key must be unique within the plugin where it is defined. Sometimes you will need to uniquely identify a module. Do this with the module complete key. A module with key fred in a plugin with key com.example.modules will have a complete key of com.example.modules:fred. i.e. The identifier of the component to import.</td>
<td>N/A</td>
</tr>
<tr>
<td>name</td>
<td></td>
<td>The human-readable name of the plugin module. i.e. the human-readable name of the component to import.</td>
<td></td>
</tr>
<tr>
<td>system</td>
<td></td>
<td>Indicates whether this plugin module is a system plugin module (value='true') or not (value='false'). Only available for non-OSGi plugins.</td>
<td>false</td>
</tr>
</tbody>
</table>

Elements

<table>
<thead>
<tr>
<th>Name</th>
<th>Required</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>description</td>
<td></td>
<td>The description of the plugin module. The 'key' attribute can be specified to declare a localisation key for the value instead of text in the element body. i.e. the description of the component to import.</td>
<td></td>
</tr>
<tr>
<td>interface</td>
<td>✓</td>
<td>The Java interface under which the component to retrieve is registered. This element can appear zero or more times, but is required if the interface attribute is not used.</td>
<td>N/A</td>
</tr>
</tbody>
</table>

Example

Here is an example `atlassian-plugin.xml` file containing a single component import:

```xml
<atlassian-plugin name="Hello World" key="example.plugin.helloworld" plugins-version="2">
  <plugin-info>
    <description>A basic component import module test</description>
    <vendor name="Atlassian Software Systems" url="http://www.atlassian.com"/>
    <version>1.0</version>
  </plugin-info>
  <component-import key="helloWorldService">
    <description>Consumes the hello world service.</description>
    <interface>com.myapp.HelloWorldService</interface>
  </component-import>
</atlassian-plugin>
```

It consumes a component made available via a different plugin:
<atlassian-plugin name="Hello World Provider" key="example.plugin.helloworld.provider" plugins-version="2">
    <plugin-info>
        <description>A basic component module test</description>
        <vendor name="Atlassian Software Systems" url="http://www.atlassian.com"/>
        <version>1.0</version>
    </plugin-info>
    <component key="helloWorldService" class="com.myapp.internal.MyHelloWorldService" public="true">
        <interface>com.myapp.HelloWorldService</interface>
    </component>
</atlassian-plugin>

Notes

Some information to be aware of when developing or configuring a Component Import plugin module:

- Component imports, at installation time, are used to generate the atlassian-plugins-spring.xml Spring Framework configuration file, transforming Component Import plugin modules into OSGi service references using Spring Dynamic Modules.
- The imported component will have its bean name set to the component import key, which may be important if using 'by name' dependency injection.
- If you wish to have more control over how imported services are discovered and made available to your plugin, you can create your own Spring configuration file containing Spring Dynamic Modules elements, stored in META-INF/spring in your plugin jar. This is recommended if you are needing to import multiple services that implement an interface, for example.
- You can use component imports to customise the bean name of host components, particularly useful if you plan to use 'by name' dependency injection.

Component Plugins

On this page:
- Recommended Plugin Module Type
- Purpose of this Module Type
- Configuration
  - Attributes
  - Elements
- Example
- Notes
- Accessing Your Components

Recommended Plugin Module Type

The Component plugin module described below is available to OSGi-based plugins using version 2.x of the Atlassian Plugin Framework, supported in Confluence 2.10 and later.

We recommend that you use the new plugin module type described below, rather than the old-style Component and Spring Component module types. Confluence still supports the earlier module types, but the new OSGi-based plugin framework fixes a number of bugs and limitations experienced by the old-style plugin modules.

Purpose of this Module Type

Component plugin modules enable you to share Java components between other modules in your plugin and optionally with other plugins in the application.

Configuration

The root element for the Component plugin module is component. It allows the following attributes and child elements for configuration:

Attributes

<table>
<thead>
<tr>
<th>Name</th>
<th>Required</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>alias</td>
<td></td>
<td>The alias to use for the component when registering it in the internal bean factory.</td>
<td>The plugin key</td>
</tr>
</tbody>
</table>
class The class which implements this plugin module. The class you need to provide depends on the module type. For example, Confluence theme, layout and colour-scheme modules can use classes already provided in Confluence. So you can write a theme-plugin without any Java code. But for macro and listener modules you need to write your own implementing class and include it in your plugin. The Java class of the component. This does not need to extend or implement any class or interface.

key The identifier of the plugin module. This key must be unique within the plugin where it is defined. Sometimes you will need to uniquely identify a module. Do this with the **module complete key**. A module with key `fred` in a plugin with key `com.example.modules` will have a complete key of `com.example.modules:fred`. I.e. the identifier of the component.

i18n-name-key The localisation key for the human-readable name of the plugin module.

name The human-readable name of the plugin module. I.e. the human-readable name of the component. The plugin key.

public Indicates whether this component should be made available to other plugins via the Component Import Plugin Module or not.

system Indicates whether this plugin module is a system plugin module (value='true') or not (value='false'). Only available for non-OSGi plugins.

### Elements

<table>
<thead>
<tr>
<th>Name</th>
<th>Required</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>interface</td>
<td></td>
<td>The Java interface under which this component should be registered. This element can appear zero or more times.</td>
<td>N/A</td>
</tr>
<tr>
<td>description</td>
<td></td>
<td>The description of the plugin module. The 'key' attribute can be specified to declare a localisation key for the value instead of text in the element body.</td>
<td></td>
</tr>
</tbody>
</table>

### Example

Here is an example `atlassian-plugin.xml` file containing a single public component:

```xml
<atlassian-plugin name="Hello World" key="example.plugin.helloworld" plugins-version="2">
  <plugin-info>
    <description>A basic component module test</description>
    <vendor name="Atlassian Software Systems" url="http://www.atlassian.com"/>
    <version>1.0</version>
  </plugin-info>

  <component key="helloWorldService" class="com.myapp.DefaultHelloWorldService">
    <description>Provides hello world services.</description>
    <interface>com.myapp.HelloWorldService</interface>
  </component>
</atlassian-plugin>
```

### Notes

Some information to be aware of when developing or configuring a Component plugin module:

- Components, at installation time, are used to generate the `atlassian-plugins-spring.xml` Spring Framework configuration file, transforming Component plugin modules into Spring bean definitions. The generated file is stored in a temporary plugin jar and installed into the framework. The plugin author should very rarely need to override this file.
- The injection model for components first looks at the constructor with the largest number of arguments and tries to call it, looking up parameters by type in the plugin’s bean factory. If only a no-arg constructor is found, it is called then Spring tries to autowire the bean by looking at the types used by setter methods. If you wish to have more control over how your components are created and configured, you can create your own Spring configuration file, stored in `META-INF/spring` in your plugin jar.
- If the `public` attribute is set to 'true', the component will be turned into an OSGi service under the covers, using Spring Dynamic Modules to manage its lifecycle.
- This module type in non-OSGi (version 1) plugins supported the StateAware interface in some products to allow a component to react to when it is enabled or disabled. To achieve the same effect, you can use the two Spring lifecycle interfaces: InitializingBean and DisposableBean. The `init()` and `destroy()` methods on these interfaces will be called when the module is enabled or disabled, exactly like StateAware. Making this change to a component in an existing plugin will be backwards compatible in all but JIRA. That is, a component module in a legacy plugin which implements InitializingBean will have its `init()` method called when it is enabled, exactly the same as such a component in an OSGi plugin.
- Components for non-OSGi (version 1) plugins behave very differently to components for OSGi plugins. For version 1 plugins, components are loaded into the application’s object container, be it PicoContainer for JIRA or Spring for all other products that
support components. For OSGi plugins, components are turned into beans for the Spring bean factory for that specific plugin. This provides more separation for plugins, but means you cannot do things like override JIRA components in OSGi plugins, as you can for static plugins.

Accessing Your Components

Accessing your components from within other plugin modules is extremely simple. All plugin modules in OSGi plugins are autowired. So to access a component, you need to add a Java setter method to your plugin module class.

For example, if you wanted to use the above `helloWorldService` component in an event listener module, you would add a field for the component and a setter method to the listener class as follows:

```java
public class MyEventListener implements EventListener {
    private HelloWorldService helloWorldService;
    // ...
    public void setHelloWorldService(HelloWorldService helloWorldService) {
        this.helloWorldService = helloWorldService;
    }
}
```

Note that to access components in other plugins, the module needs to be marked as 'public' (as covered above) and imported into your plugin using a `component-import`.

Component Plugins - Old Style

This is an outdated module type

The Component plugin module described below belongs to the first version of the Atlassian Plugin Framework. A new Component plugin module is available to OSGi-based plugins using version 2.x of the Atlassian Plugin Framework, supported in Confluence 2.10 and later.

On this page:

- Old-Style Plugin Module Type
- Purpose of this Module Type
- Component Plugin Module
- Accessing Your Components
  - Autowired Objects
  - Non-autowired Objects
- Notes

Old-Style Plugin Module Type

We recommend that you use the new plugin module type, rather than the old-style Component described below. Confluence still supports the earlier module type, but the new OSGi-based plugin framework fixes a number of bugs and limitations experienced by the old-style plugin modules.

Purpose of this Module Type

Component plugin modules enable you to add components to Confluence's internal component system (powered by Spring).

Component plugin modules are available in Confluence 1.4 and later.

Component Plugin Module

Each component module adds a single object to Confluence’s component management system.

Other plugins and objects within Confluence can then be autowired with your component. This is very useful for having a single component that is automatically passed to all of your other plugin modules (ie a Manager object).

Here is an example `atlassian-plugin.xml` file containing a single component module:
the name attribute represents how this component will be referred to in the interface.
the key attribute represents the internal, system name for your component.
the class attribute represents the class of the component to be created
the alias attribute represents the alias this component will be stored with. This element is optional, if not specified the module key will be used instead.

Accessing Your Components

Accessing your components is extremely simple.

Autowired Objects

If your object is being autowired (for example another plugin module or an XWork action), the easiest way to access a component is to add a basic Java setter method.

For example, if you use the above BogusComponent module your object would retrieve the component as follows:

```java
public void setBogusComponent(BogusComponent bogusComponent) {
    this.bogusComponent = bogusComponent;
}
```

Non-autowired Objects

If your object is not being autowired, you may need to retrieve the component explicitly. This is done via the ContainerManager like so:

```java
BogusComponent bc = (BogusComponent) ContainerManager.getComponent("bogusComponent");
```

Notes

Some issues to be aware of when developing a component:

- One component module can depend on another component module but be careful of circular references (ie A requires B, B requires A).
- The component “namespace” is flat at the moment, so choose a sensible alias for your component.

Decorator Plugins

Decorator plugin modules are available in Confluence 2.5 and later versions

Decorator plugin modules allow you to add decorators without using a Theme Plugin.

- For more information about plugins in general, read Confluence Plugin Guide.
- To learn how to install and configure plugins (including macros), read Installing and Configuring Plugins Manually.
- For an introduction to writing your own plugins, read Writing Confluence Plugins

Decorator Plugin Module

The following is an example atlassian-plugin.xml file containing a single decorator:
• the `page` attribute of `decorator` defines the name of the decorator resource file
• the `pattern` element defines the url pattern for which the decorator will be applied to (you can only have one pattern per decorator)

**Decorator resource file**

Decorator files are written in the Velocity templating language and have the VMD extension. The following is a sample decorator file:

```html
<html>
<head>
    <title>$title</title>
</head>
<div id="PageContent">
    <table class="pagecontent" border="0" cellpadding="0" cellspacing="0" width="100%">
        <tr>
            <td valign="top" class="pagebody">
                <div class="pageheader">
                    <span class="pagetitle">$title</span>
                </div>
                $body
            </td>
        </tr>
    </table>
</div>
</body>
</html>
```

You can familiarise yourself with Velocity at the [Velocity Template Overview](https://sitemesh.apache.org/) and decorators in general at the [Sitemesh homepage](https://sitemesh.apache.org/).

**Editor Plugins**

Editor plugin modules are available in Confluence 2.5 and later versions

Editor plugin modules allow you to implement WYSIWYG editors for editing Confluence pages. Currently, Confluence only supports the use of one WYSIWYG editor during editing even if there are multiple editor plugins enabled. It is not guaranteed that any one editor will be used over another, hence it is recommended that only one editor is enabled at a time.

• For more information about plugins in general, read [Confluence Plugin Guide](https://confluence.atlassian.com/pages/overview/confluence-plugin-guide).
• To learn how to install and configure plugins (including macros), read [Installing and Configuring Plugins Manually](https://confluence.atlassian.com/pages/overview/confluence-plugin-guide).
• For an introduction to writing your own plugins, read [Writing Confluence Plugins](https://confluence.atlassian.com/pages/overview/confluence-plugin-guide).

**Editor Plugin Module**

The following is a snippet of `atlassian-plugin.xml` from the TinyMCE Editor:

```xml
<atlassian-plugin key="com.atlassian.confluence.extra.tinymceplugin" name="TinyMCE Editor Plugin">
    <plugin-info>
        <description>TinyMCE Editor Plugin for Confluence</description>
        <vendor name="Atlassian" url="http://www.atlassian.com"/>
        ...
    </plugin-info>
    <editor name="tinymceeditor" class="com.atlassian.confluence.extra.tinymceplugin.TinymceEditor" key="tinymceeditor">
        <description>TinyMCE Editor</description>
    </editor>
    ...
</atlassian-plugin>
```

The `class` attribute defines the Java class for which the editor will interact with Confluence. This class must implement `com.atlassian.confluence.plugin.editor`. 
All editors must implement the following interface:

```java
package com.atlassian.confluence.plugin.editor;

/**
 * This interface allows Wysiwyg editors to be plugged in to Confluence.
 */
public interface Editor
{
    /**
     * Returns javascript functions to allow the wiki-textarea.vm to interface with the editor.
     * The Javascript returned must define the functions:
     * - onShowEditor() -- this is called just after the DIV containing the editor is made visible. It is a hook where you
     *      can place any special code needed at this point.
     * - onHideEditor() -- this is called just before the DIV containing the editor is hidden. It
     *      is a hook where you
     *      can place any special code needed at this point.
     * - setEditorValue(newValue) -- put the text in newValue into the editor. This is called
     *      when the editor needs new
     *      content -- it is *not* called to set the initial content. That should be done
     *      either by providing the
     *      editor with the content as part of the initial HTML or by calling javascript from
     *      editorOnLoad().
     * - allowModeChange() -- return true if the editor is in a state where changes from rich
text to markup and vice versa are allowed.
     * - getEditorHTML() -- return the current HTML contents of the editor. This *must* return a
     *      JavaScript string,
     *      not a JavaObject wrapping a java.lang.String!
     * - editorOnLoad() -- called in the page’s onLoad handler, place any initialization needed
     *      at this point here.
     * - editorHasContentChanged() -- return true if the contents of the editor has been modified
     *      by the user since
     *      the last time editorResetContentChanged().
     * - editorResetContentChanged() -- called to reset the contents change indicator
     *      Note these methods won’t be called when the editor is not visible.
     * - The javascript must be surrounded by a <script> element.
     * @return a String containing a velocity template
     */
    String getJavascriptTemplate();

    /**
     * Returns the div contents to display the editor itself.
     * @return a String containing a velocity template
     */
    String getDivContentsTemplate();

    /**
     * Return true if the user agent string indicates a browser which is supported by this
     * editor.
     * @param userAgent
     * @return true if this editor is supported
     */
    boolean supportedUserAgent(String userAgent);

    /**
     * Perform any necessary escaping of the HTML rendered by Confluence. The
     * AbstractPreviewPageAction.getWysiwygContent() method uses this method to escape the rendered HTML.
     * @param html
     * @return a String containing a velocity template
     */
    String escapeHtml(String html);

    /**
     * Return a string of CSS which will be appended to the standard stylesheet if it is
     * requested from /styles/wysiwyg-action
     * Note that it is up to the editor implementation to retrieve this stylesheet and apply it
     * to the editor contents --
     * the page containing the editor is styled with the normal stylesheet.
     */
    String getEditorSpecificCss();
}
```

For an example, you can view the source for the TinyMCE Plugin.

**Event Listener Plugins**
Every time something important happens within Confluence (a page is added or modified, the configuration is changed, etc.), an ‘event’ is triggered. Listeners allow you to extend Confluence by installing code that responds to those events.

**Availability**
Listener plugins are available in Confluence 1.4 and later.

**Plugin Events**
It is possible to listen for plugin install/uninstall/enable/disable events, however this will be unreliable when trying to listen for events about your own plugin. You will *not* receive a PluginDisableEvent or PluginUninstallEvent for the plugin itself. To trigger actions for these events, one (or more) of your modules (macro, event listener, etc.) should implement the Making Your Plugin Modules State Aware interface instead.

**Synchronous Events**
Confluence events are currently processed synchronously - that is, Confluence will wait for your event to finish processing before returning from the method that was the source of the event. This makes it *very important* that any event listener you write completes as quickly as possible.

Asynchronous events will be forthcoming in a future Developer Release.

### Adding a listener plugin

Listeners are a kind of Confluence plugin module.

- For more information about plugins in general, read Confluence Plugin Guide.
- To learn how to install and configure plugins (including macros), read Installing and Configuring Plugins Manually.
- For an introduction to writing your own plugins, read Writing Confluence Plugins

#### The Listener Plugin Module

Each listener is a plugin module of type “listener”, packaged with whatever Java classes and other resources that the listener requires in order to run. Here is an example atlassian-plugin.xml file containing a single listener:

```xml
<atlassian-plugin name='Optional Listeners' key='confluence.extra.auditor'>
  <plugin-info>
    <description>Audit Logging</description>
    <vendor name='Atlassian Software Systems' url='http://www.atlassian.com'/>
    <version>1.0</version>
  </plugin-info>
  <listener name='Audit Log Listener' class='com.example.listener.AuditListener' key='auditListener'>
    <description>Provides an audit log for each event within Confluence.</description>
  </listener>
</atlassian-plugin>
```

The listener module definition has no configuration requirements beyond any other module: just give it a name, a key, and provide the name of the class that implements the listener.

#### The Listener Class

The **class** attribute of the listener module definition must refer to a Java class that implements the `com.atlassian.confluence.event.EventListener` interface. This is the interface:
Events and Event Types

All events within Confluence extend from com.atlassian.com.event.events.ConfluenceEvent. In general, we use the following convention for naming each type of ConfluenceEvent:

\[ <Object><Operation>Event \]

For example, we have the following event types relating to space events: SpaceCreateEvent, SpaceUpdateEvent, SpaceRemoveEvent. In the above description, space would correspond to \(<Object>\) and create, update, or remove would correspond to \(<Operation>\).

Occasionally, an operation is so singular that its meaning will be obvious without use of this naming convention; for example a LoginEvent or ConfigurationEvent.

A full catalogue of the events available within Confluence will be forthcoming before the 1.4 final release.

Limitations of Events

- Events are a notification that something has occurred. The event system is not designed to allow a listener to veto the action that caused the event.
- There is no loop-detection. If you write a listener for the SpaceModifiedEvent that itself causes a SpaceModifiedEvent to be generated, you are responsible for preventing the ensuing infinite loop.

Example Code

A more detailed example, with sample code, can be found in Writing an Event Listener Plugin Module.

Writing an Event Listener Plugin Module

Overview

For an introduction to event listener plugin modules, please read Event Listener Plugins.

Writing an Event Listener as a plugin module within Confluence

Writing an event listener is a four-step process:

```java
package com.atlassian.confluence.event;
import com.atlassian.confluence.event.events.ConfluenceEvent;

public interface EventListener {
    void handleEvent(ConfluenceEvent event);
}
```
1. Identify the events you wish to listen for
2. Create the EventListener Java class
   a. Implement getHandledEventClasses()
   b. Implement handleEvent()
3. Add the listener module to your atlassian-plugin.xml file

Identify the events you wish to listen for

The easiest thing here is to consult the latest API, in the package com.atlassian.confluence.event.events. When you implement an EventListener you will provide an array of Class objects which represent the events you wish to handle.

The naming of most events are self explanatory (GlobalSettingsChangedEvent or ReindexStartedEvent for example), however there are some which need further clarification:

<table>
<thead>
<tr>
<th>Event Class</th>
<th>Published</th>
</tr>
</thead>
<tbody>
<tr>
<td>LabelCreateEvent</td>
<td>On the creation of the first label to the target Content Entity Object.</td>
</tr>
<tr>
<td>LabelRemoveEvent</td>
<td>On the removal of the last label from the target Content Entity Object.</td>
</tr>
<tr>
<td>LabelAddEvent</td>
<td>On the addition of any label to the target Content Entity Object.</td>
</tr>
<tr>
<td>LabelDeleteEvent</td>
<td>On the deletion of any label from the target Content Entity Object.</td>
</tr>
</tbody>
</table>

Create the EventListener

The EventListener interface defines two methods which must be implemented: getHandledEventClasses() and handleEvent().

Implement getHandledEventClasses()

The getHandledEventClasses() method holds an array of class objects representing the events you wish to listen for.

- Your listener will only receive events of the types specified in getHandledEventClasses()
- You must specify all the event types you need - specifying a superclass will not include its subclasses
- Returning an empty array will cause your listener to receive every event Confluence produces

So, if you want your listener to receive only SpaceCreatedEvent and SpaceRemovedEvent:

```java
private static final Class[] HANDLED_EVENTS = new Class[] {
    SpaceCreateEvent.class, SpaceRemovedEvent.class
};

public Class[] getHandledEventClasses()
{
    return HANDLED_EVENTS;
}
```

Alternatively, to receive all possible events:

```java
/**
 * Returns an empty array, thereby handling every ConfluenceEvent
 * @return
 */
public Class[] getHandledEventClasses()
{
    return new Class[0];
}
```

Implement handleEvent()

The implementation below simply relies upon the toString() implementation of the event and logs it to a log4j appender.

```java
public void handleEvent(ConfluenceEvent event)
{
    if (!initialized)
    {
        initializeLogger();
    }

    log.info(event);
}
```

Most often, a handleEvent(...) method will type check each event sent through it and execute some conditional logic.
A full example of an EventListener class that listens for login and logout events can be found in EventListener Example.

Add the EventListener as a module to your plugin by creating an atlassian-plugin.xml

The atlassian-plugin.xml file has been described elsewhere in detail. This is an example of a listener plugin module included in an atlassian-plugin.xml file.

```
<atlassian-plugin name='Optional Listeners' key='confluence.extra.auditor'>
  <plugin-info>
    <description>Audit Logging</description>
    <vendor name="Atlassian Software Systems" url="http://www.atlassian.com"/>
    <version>1.0</version>
  </plugin-info>
  <listener name='Audit Log Listener' class='com.atlassian.confluence.extra.auditer.AuditListener' key='auditListener'>
    <description>Provides an audit log for each event within Confluence.</description>
  </listener>
</atlassian-plugin>
```

EventListener Example

Find an example of an EventListener below, which listens for the LoginEvent and LogoutEvent.

```java
public void handleEvent(ConfluenceEvent event)
{
  if (event instanceof LoginEvent)
  {
    LoginEvent loginEvent = (LoginEvent) event;
    // ... logic associated with the LoginEvent
  }
  else if (event instanceof LogoutEvent)
  {
    LogoutEvent logoutEvent = (LogoutEvent) event;
    // ... logic associated with the LogoutEvent
  }
}
```
Extractor Plugins

Extractor plugins allow you to hook into the mechanism by which Confluence populates its search index. Each time content is created or updated in Confluence, it is passed through a chain of extractors that assemble the fields and data that will be added to the search index for that content. By writing your own extractor you can add information to the index.

Extractor plugins can be used to extract the content from attachment types that Confluence does not support.

- For more information about plugins in general, read Confluence Plugin Guide.
- To learn how to install and configure plugins (including macros), read Installing and Configuring Plugins Manually.
- For an introduction to writing your own plugins, read Writing Confluence Plugins.
- Extractor plugins are closely tied to the API of the Lucene Java library.

Confluence's internal search is built on top of the Lucene Java library. While familiarity with Lucene is not an absolute requirement for writing an extractor plugin, you'll need it to write anything more than the most basic of plugins.

Extractor Plugins
Here is an example `atlassian-plugin.xml` file containing a single search extractor:

```xml
<atlassian-plugin name="Sample Extractor" key="confluence.extra.extractor">
...

<extractor name="Page Metadata Extractor" key="pageMetadataExtractor"
class="confluence.extra.extractor.PageMetadataExtractor" priority="1000">
<description>Extracts certain keys from a page's metadata and adds them to the search index.</description>
</extractor>
...
</atlassian-plugin>
```

- the `class` attribute defines the class that will be added to the extractor chain. This class must implement `bucket.search.lucene.Extractor`.
- the `priority` attribute determines the order in which extractors are run. Extractors are run from the highest to lowest priority. Extractors with the same priority may be run in any order.

As a general rule, all extractors should have priorities below 1000, unless you are writing an extractor for a new attachment type, in which case it should be greater than 1000.

If you are not sure what priority to choose, just go with `priority="900"` for regular extractors, and `priority="1200"` for attachment content extractors.

To see the priorities of the extractors that are built into Confluence, look in `WEB-INF/classes/plugins/core-extractors.xml` and `WEB-INF/classes/plugins/attachment-extractors.xml`. From Confluence-2.6.0, these files are packaged inside `confluence-2.6.0.jar`; we have instructions for Editing Files within JAR Archives if you’re unfamiliar with the process.

### The Extractor Interface

All extractors must implement the following interface:

```java
package bucket.search.lucene;

import bucket.search.Searchable;

public interface Extractor
{
    public void addFields(Document document, StringBuffer defaultSearchableText, Searchable searchable);
}
```

- The `document` parameter is the Lucene document that will be added to the search index for the object that is being saved. You can add fields to this document, and the fields will be associated with the object in the index.
- The `defaultSearchableText` is the main body of text that is associated with this object in the search index. It is stored in the index as a `Text` field with the key “content”. If you want to add text to the index such that the object can be found by a regular Confluence site search, append it to the `defaultSearchableText`. (Remember to also append a trailing space, or you’ll confuse the next piece of text that’s added!)  
- The `searchable` is the object that is being saved, and passed through the extractor chain.

### Attachment Content Extractors

If you are writing an extractor that indexes the contents of a particular attachment type (for example, OpenOffice documents or Flash files), you should extend the abstract class `bucket.search.lucene.extractor.BaseAttachmentContentExtractor`. This class ensures that only one attachment content extractor successfully runs against any file (you can manipulate the priorities of attachment content extractors to make sure they run in the right order).

For more information, see: Attachment Content Extractor Plugins

### An Example Extractor

The following example extractor is untested, but it associates a set of page-level properties with the page in the index, both as part of the regular searchable text, and also as Lucene Text fields that can be searched individually, for example in a custom `{abstract-search}` macro.
Debugging

There's a really primitive Lucene index browser hidden in Confluence which may help when debugging. You'll need to tell it the filesystem path to your $conf-home/index directory.

http://yourwiki.example.com/admin/indexbrowser.jsp

Attachment Content Extractor Plugins

Extractor plugin modules are available in Confluence 1.4 and later

Attachment content extractor plugins enable Confluence to index the contents of attachments that it may not otherwise understand. Before you read this document, you should be familiar with Extractor Plugins.

The BaseAttachmentContentExtractor class

Attachment content extractor plugins must extend the bucket.search.lucene.extractor.BaseAttachmentContentExtractor base class. The skeleton of this class is:

```java
package com.example.extras.extractor;
import bucket.search.lucene.Extractor;
import bucket.search.Searchable;
import org.apache.lucene.document.Field;
import com.atlassian.confluence.core.ContentEntityObject;
import com.atlassian.confluence.core.ContentPropertyManager;
import com.opensymphony.util.TextUtils;

class ContentPropertyExtractor implements Extractor {
    public static final String[] INDEXABLE_PROPERTIES = {"status", "abstract"};

    private ContentPropertyManager contentPropertyManager;

    public void addFields(Document document, StringBuffer defaultSearchableText, Searchable searchable) {
        if (searchable instanceof ContentEntityObject) {
            ContentEntityObject contentEntityObject = (ContentEntityObject) searchable;
            for (int i = 0; i < INDEXABLE_PROPERTIES.length; i++) {
                String key = INDEXABLE_PROPERTIES[i];
                String value = contentPropertyManager.getStringProperty(contentEntityObject, key);
                if (TextUtils.stringSet(value)) {
                    defaultSearchableText.append(value).append(" ");
                    document.add(new Field(key, value, Field.Store.YES, Field.Index.TOKENIZED));
                }
            }
        }
    }

    public void setContentPropertyManager(ContentPropertyManager contentPropertyManager) {
        this.contentPropertyManager = contentPropertyManager;
    }
}
```
The first attachment content extractor that returns true from `shouldExtractFrom` and a not-null, not-empty String from `extractText()` will cause all remaining attachment content extractors not to run against this file. Thus, it's important to get the priority value for your plugin right, so general, but inaccurate extractors are set to run after specific, more accurate extractors.

Other (non-attachment) content extractors will still run, regardless.

**An Example**

This is an example of a hypothetical extractor that extracts the contents of mp3 ID3 tags.
Job Plugins

Job plugin modules are available in Confluence 2.2 and later.

Job plugin modules enable you to add repeatable tasks to Confluence, which are in turn scheduled by Trigger Plugins.

- For more information about plugins in general, read Confluence Plugin Guide.
- To learn how to install and configure plugins (including macros), read Installing and Configuring Plugins Manually.
- For an introduction to writing your own plugins, read Writing Confluence Plugins

Job Plugin Module

The Job plugin module adds a simple reusable component within a plugin. At a minimum, the module class must implement Quartz's Job interface, but for access to Confluence's objects and database you should extend com.atlassian.quartz.jobs.AbstractJob. Jobs are scheduled with Trigger Plugins.

Note that at the moment Jobs are not autowired by Spring.

Here is an example atlassian-plugin.xml fragment containing a single Job module:

```xml
<atlassian-plugin name="Sample Component" key="confluence.extra.component">
  ...
  <job key="myJob" name="My Job" class="com.example.myplugin.jobs.MyJob"/>
  ...
</atlassian-plugin>
```

- the name attribute represents how this component will be referred to in the Confluence interface.
- the key attribute represents the internal, system name for your Job. This is what the Trigger will refer to.
- the class attribute represents the class of the Job to be created. The class must have a no-argument constructor, or it will not be able to be instantiated by Confluence.

For examples of how to schedule Jobs to be run, see Trigger Plugins.

Note that in Confluence 2.3 you can also use a Spring Plugin as a job. This allows you to inject other Spring components into the Job, via the "jobDataAsMap" property of the job. An example is shown below. You cannot do this in Confluence 2.2.

```java
package com.example.extras.extractor;
import com.hypothetical.id3.Id3Tag;
import bucket.search.lucene.extractor.BaseAttachmentContentExtractor;
import bucket.search.lucene.SearchableAttachment;
import java.io.InputStream;
import java.io.IOException;
public class Id3Extractor extends BaseAttachmentContentExtractor {
    public static final String[] MIME_TYPES = {
        "audio/x-mp3", "audio/mpeg", "audio/mp4a-latm"};
    public static final String[] FILE_EXTS = {"mp3", "m4a"};
    protected String extractText(InputStream is, SearchableAttachment attachment) throws IOException {
        Id3Tag tag = Id3Tag.parse(is);
        return (tag.getTitle() + " " + tag.getArtist() + " " + tag.getGenre() + " " + tag.getAlbumTitle());
    }
    protected String[] getMatchingContentTypes() {
        return MIME_TYPES;
    }
    protected String[] getMatchingFileExtensions() {
        return FILE_EXTS;
    }
}
```
Spring Job definition only supported with bundled plugins

Plugins containing Spring JobDetailBeans can't be dynamically loaded at present, due to classloading issues.

```xml
<spring name="Space Cleaner Job" key="spaceCleanerJob" id="spaceCleanerJob" class="org.springframework.scheduling.quartz.JobDetailBean">
    <property name="name">
        <value>Space Cleaner Job</value>
    </property>
    <property name="jobClass">
        <value>com.atlassian.confluence.extras.spacecleaner.SpaceCleanerJob</value>
    </property>
    <property name="jobDataAsMap">
        <map>
            <entry key="spaceManager"> <!-- these spring beans will be injected into the SpaceCleanerJob instance -->
                <ref bean="spaceManager"/>
            </entry>
            <entry key="pageManager">
                <ref bean="pageManager"/>
            </entry>
            <entry key="settingsManager">
                <ref bean="settingsManager"/>
            </entry>
            <entry key="trashManager">
                <ref bean="trashManager"/>
            </entry>
            <entry key="runOncePerCluster">
                <value>true</value>
            </entry>
        </map>
    </property>
</spring>

<trigger key="com.atlassian.confluence.extras.spacecleaner.SpaceCleanerJob.trigger" name="Space Cleaner Trigger">
    <job key="spaceCleanerJob"/>
    <schedule cron-expression="0 * * * * ?"/>
</trigger>
```

Language Pack Plugins

To run Confluence in another language, you must install a language pack plugin for that translation. Guides and tools for collaboratively creating translations have been made available to the Confluence community.

This page provides a technical overview of plugins, for users interested in creating or updating a translation. To install a translation, check out Community Translations.

Translations for the Rich Text Editor can be part of a Confluence language pack plugin.

Language Pack Overview

Language plugins are placed in the `<CONFLUENCE-INSTALL-DIRECTORY>/languages/<KEY>` directory, where `<KEY>` is the international language identifier. They consist of three files:

<table>
<thead>
<tr>
<th>Name</th>
<th>Purpose</th>
<th>Filename</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language Plugin Descriptor</td>
<td>Defines language settings in</td>
<td>atlassian-plugin.xml</td>
<td>./src/etc</td>
</tr>
<tr>
<td></td>
<td>language tag</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ConfluenceActionSupport</td>
<td>Contains text strings in key:value mapping</td>
<td>ConfluenceActionSupport&lt;KEY&gt;.properties</td>
<td>./src/etc/com/atlassian/confluence</td>
</tr>
<tr>
<td>Properties File</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Flag Image

| Contains flag image for country | <KEY>.png | ./src/etc/templates/languages/<KEY> |

**Directory Structure**

The location of the three files that compose a Language Pack plugin is as follows:

```
./src/etc/com/atlassian/confluence/<PATH_OF_PROPERTIES_FILE>
./src/etc/templates/languages/<LANGUAGE_KEY>/<LANGUAGE_KEY>.gif
./src/etc/atlassian-plugin.xml
```

As an example, this is the directory listing of the German translation ("de_DE"):

```
./confluence-2.2-std/plugins/de_DE/src
./confluence-2.2-std/plugins/de_DE/src/etc/atlassian-plugin.xml
./confluence-2.2-std/plugins/de_DE/src/etc/com
./confluence-2.2-std/plugins/de_DE/src/etc/com/atlassian
./confluence-2.2-std/plugins/de_DE/src/etc/com/atlassian/confluence
./confluence-2.2-std/plugins/de_DE/src/etc/com/atlassian/confluence/core
./confluence-2.2-std/plugins/de_DE/src/etc/atlassian/confluence/core/ConfluenceActionSupport_de_DE.properties
```

**Language Plugin Structure**

The three components of a plugin must be updated for each translation. The following sections describe updating the language plugin descriptor, flag image and ConfluenceActionSupport properties file.

**Defining The Language Plugin Descriptor**

This is an example atlassian-plugin.xml file for a Language Pack plugin for German:

```xml
<atlassian-plugin name='German language pack' key='confluence.languages.de_DE'>
  <plugin-info>
    <description>This plugin contains translations for the German language</description>
    <vendor name="Atlassian Software Systems" url="http://www.atlassian.com" />
    <version>1.0</version>
  </plugin-info>
  <language name="German" key="de_DE" language="de" country="DE">
    <!-- Define a flag that will be shown for this language -->
    <resource name="de_DE.gif" type="download" location="templates/languages/de_DE/de_DE.gif">
      <property key="content-type" value="image/gif" />
    </resource>
  </language>
</atlassian-plugin>
```

**Language Plugin Descriptor Attributes**

The atlassian-plugin.xml file declares the language being bundled using the following attributes:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>language</td>
<td>The language being defined</td>
<td>Yes</td>
</tr>
<tr>
<td>country</td>
<td>The country the language belongs to</td>
<td>No</td>
</tr>
<tr>
<td>variant</td>
<td>The variant of the language</td>
<td>No</td>
</tr>
</tbody>
</table>

These values are based off those defined in the java.util.Locale class. For information on the valid values for the language, country and variant attributes, please see the java.util.Locale documentation.

The key attribute is an aggregation of the the three previous attributes, in the same format as that of java.util.Locale:
language[.country][.variant]

**Flag Images**
Language packs define a flag that is to be used to represent the language. The \texttt{atlassian-plugin.xml} defines the language property:

\begin{verbatim}
<resource name="en_AU.gif" type="download" location="templates/languages/en_AU/en_AU.gif">
<property key="content-type" value="image/gif"/>
</resource>
\end{verbatim}

When selecting a language, the flag defined above will be displayed. Additionally, the flag will appear during the setup process.

\textbf{ConfluenceActionSupport Properties File}

This Java Properties file contains key-value pairs for each string in Confluence, and supports variables. For example:

\begin{verbatim}
remove.all.name=Remove All
view.mail.thread.desc.full=Entire Thread (Showing \{0\} of \{1\})
\end{verbatim}

\textbf{Creating A New Confluence Translation}

If you would like to translate Confluence into your local language, follow the instructions below on creating a language pack plugin from an example.

The Confluence community is sharing their in-progress and complete translations. You should check that a shared translation to your target language has not already been started here.

\textbf{Preparation}

Start by checking out the technical overview of a Language Pack Plugin. Once you are familiar with the structure and content of a plugin, you can move on to creating your own:

1. Check that you have the latest version of Confluence here. If not, you are recommended to install the latest version for translation, though you can use any version newer than 2.2. Refer to the guide on Upgrading Confluence for instructions.
2. If you do not already have Apache Ant installed, download the latest version and setup your environmental variables according to the manual.
3. If you are using Confluence 2.2.0 only, you will need to unzip the language plugin base files from \texttt{languages.zip} into a subdirectory of \texttt{<CONFLUENCE-INSTALL-DIRECTORY> languages}.

\textbf{Modifying The Example Language Pack Settings}

This example will work from an example plugin \texttt{en_AU.zip}.

1. Unzip the example \texttt{en_AU} language pack \texttt{en_AU.zip} into a subdirectory of \texttt{<CONFLUENCE-INSTALL-DIRECTORY>/languages} called \texttt{en_AU}. Note that the file is just a renamed copy of default English properties file.
2. We will now update the properties file in the example to the latest version. Open your Confluence install directory and copy the\texttt{confluence\WEB-INF\classes\com\atlassian\confluence\core\ConfluenceActionSupport.properties} file to the example plugin directory \texttt{src/etc/com\atlassian\confluence\core}.
4. Locate the plugin descriptor file, ConfluenceActionSupport properties file and flag image.

\begin{verbatim}
<CONFLUENCE-INSTALL-DIRECTORY>/languages/en_AU/src/etc/atlassian-plugin.xml
<CONFLUENCE-INSTALL-DIRECTORY>/languages/en_AU/src/etc/com/atlassian/confluence/core/ConfluenceActionSupport.properties
\end{verbatim}

5. Determine your language plugin key \texttt{<KEY>} using your country and locale according to the Language Pack Plugins guide.
6. Atlassian has licensed a set of flags for use with translations. Delete \texttt{en_AU.png} and download the appropriate flag from Language Pack Flags, renaming it to the correct key.
7. Update \texttt{atlassian-plugin.xml} to contain the relevant \texttt{<KEY>} and other references, including image type. Refer to the first section from the above Language Pack Plugins for help on deciding what to modify.
8. Rename the directory structure and filenames that contain \texttt{en-AU} to your own \texttt{<KEY>}. The directory should now appear as:

\begin{verbatim}
<CONFLUENCE-INSTALL-DIRECTORY>/languages/<KEY>/src/etc/atlassian-plugin.xml
<CONFLUENCE-INSTALL-DIRECTORY>/languages/<KEY>/src/etc/com/atlassian/confluence/core/ConfluenceActionSupport.properties
<CONFLUENCE-INSTALL-DIRECTORY>/languages/<KEY>/src/etc/templates/languages/<KEY>/<KEY>.png
\end{verbatim}

\textbf{You are now ready to build the plugin with the default English text to check that your setup is are correct. These next few steps...}
Given Confluence 3.0 Documentation

deploy the default English version of the pack under your own language

9. From the command line, go to `<CONFLUENCE-INSTALL-DIRECTORY>/languages` and execute

```
    ant -Dlanguage=<KEY> build
```

11. Restart Confluence

12. From your browser, login as an Administrator, then go to Administration -> Language and verify that you are able to select the translation

**Updating The Language Pack**

To collaborate on the translation process, you may wish to upload your translation to the Community Translations page. Repeat these instructions to test each iteration of your translation attempt.

1. Unzip `excelbundle0.9.zip` to your local drive.

2. Browse to your Confluence install and go to the \confluence\WEB-INF\classes\com\atlassian\confluence\core directory. Copy the `ConfluenceActionSupport.properties` file there into the `translation_tool` directory and rename it to `ConfluenceActionSupport_en.properties`.

3. If you want to start a fresh translation, skip this step. To work from an existing translation, copy it into the `translation_tool` directory and remove any country variant from the filename, e.g., `ConfluenceActionSupport_ru_RU.properties` becomes `ConfluenceActionSupport_ru.properties`.

4. Call the translation tool to create the spreadsheet file. For example, to create a Russian translation, open a terminal window in the `translation_tool` directory and call

```
    java -jar excelbundle.jar -export translation_ru.xls -l en,ru -r "%cd%"
```

Edit the file content, referring to Translating ConfluenceActionSupport Content for more information on how to modify the string values.

Call the translation tool to export the updates back into the localised properties file. For the example Russian translation, open a terminal window, go to the `translation_tool` directory and call

```
    java -jar excelbundle.jar -import translation_ru.xls -l ru -r "%cd%"
```

Once you have completed editing, you must copy and rename the localised translation back to the language plugin directory. For frequent updates, you may wish to create a script to do this.

To view the updates after copying across the new properties file, select the language plugin for your translation, then restart Confluence and refresh your browser.

**Building The Language Pack Plugin**

To build the new language pack plugin, execute Ant in the `confluence\src\etc\languages` directory:

```
    ant -Dlanguage=<LANGUAGE> build
```

A JAR will be created in the `languages/<LANGUAGE>/dist/` folder.

**Installation On A Confluence Server**

To install the translation in another instance of Confluence.

1. Copy `languages-<KEY>.jar` into the `<CONFLUENCE-INSTALL-DIRECTORY>/confluence/WEB-INF/lib` of your target installation

2. Restart Confluence

3. From your browser, login as an Administrator, then go to Administration -> Language and select the translation

**Submitting A Translation (Optional)**

If you would like to share your completed translation with other Confluence users, you can upload it here.
By providing Atlassian permission to bundle complete translations with the Confluence install you will soon be able to select your local language from the Confluence translations list under System Administration, without needing to package it as a plugin.

**Language Pack Flags**

Below are flags that can be used with Language Pack Plugins in Confluence. For individual country names, see the attachments list.

These images are only for us within Confluence plugins and may not be redistributed with any other code. For license details, see license.txt
Translating ConfluenceActionSupport Content

Guide for translating the values for each property in a ConfluenceActionSupport_<KEY>.properties file, where <KEY> is the international language identifier:

Translating Strings Without Variables Or Links

These links can be translated directly. Using German in this example

submit.query.name=Submit Query

can be translated directly into

submit.query.name=Anfrage senden

Translating Strings Containing Variables Or Links
Some strings use variables or hyperlinks to provide contextual information. Variables are shown as \{NUMBER\} while hyperlinks are shown as \(<a href="\{NUMBER\}\">LINK ALIAS</a>\). Translations must take into account the positioning of variables, and check that links occur over the relevant phrase. Using German again as an example:

\[
\text{search.include.matches.in.other.spaces=There are } \langle b \rangle \{0\} \text{ matches } \langle b \rangle \text{ in } \langle b \rangle \text{ other spaces} \langle /b \rangle. \langle a href="\{1\}\">\text{Include these matches}\langle /a \rangle.
\]

This tag uses a variable to show the number of matches, and a link the user can click to include those matches. The German version must place the 'matches' variable in the adjusted location, and reapply the hyperlink to the relevant phrase:

\[
\text{search.include.matches.in.other.spaces=Es wurden } \langle b \rangle \{0\} \text{ Resultate } \langle b \rangle \text{ in } \langle b \rangle \text{ anderen Spaces} \langle /b \rangle \text{ gefunden. } \langle a href="\{1\}\">\text{Diese Resultate einschliessen}\langle /a \rangle.
\]

### Translations for the Rich Text Editor

The Rich Text Editor provided by Confluence is TinyMCE. In Confluence version 2.2.10 and above it is possible to provide translations for the tooltips and labels in the Rich Text Editor.

Most of the editor's internationalised text consists of its tooltips. There are also a few labels such as those in the Image Properties dialog. If you are using Confluence in a language other than English, you will want to translate these messages as well as the standard Confluence text.

Confluence fully supports internationalisation of the rich text editor:

- The translations for the rich text editor can be part of a Confluence language pack plugin. The TinyMCE properties can be included in the ConfluenceActionSupport properties file, along with the standard Confluence properties.
- If your language pack does not contain translations for the rich text editor, the text will show in English.

#### Creating a new translation

The core editing strings for the Rich Text Editor translations are found in the `tinymce.properties` file.

Add a new i18n plugin resource to `atlassian-plugin.xml` like this:

```
<resource name="i18n" type="i18n" location="com/atlassian/confluence/tinymceplugin/tinymce"/>
```

Now, put your translations (as described below) in `tinymce_locale.properties` (where locale is the target locale - e.g. de_DE) under the directory `src/main/resources/com/atlassian/confluence/tinymceplugin`.

#### Example

Below is a partial listing of the core TinyMCE properties. The properties consist of 'key=value' pairs. To translate from English to another language, you would replace the text to the right of the '=' sign with the translation.

```
# English
## TinyMCE core
tinymce.bold_desc=Bold (Ctrl+B)
tinymce.italic_desc=Italic (Ctrl+I)
tinymce.underline_desc=Underline (Ctrl+U)
tinymce.striketrough_desc=Strikethrough

## paste plugin
tinymce.paste.paste_text_desc=Paste as Plain Text
tinymce.paste.paste_text_title=Use CTRL+V on your keyboard to paste the text into the window.
tinymce.paste.paste_text_linebreaks=Keep linebreaks
```

#### Updating A Confluence Translation

This guide is for translating Confluence into non-English languages using a Spreadsheet, and covers:

1. Improving or finishing a translation for an existing Language Plugin
2. Updating an existing translation for a new version of Confluence

If you do not have a Language Plugin to deploy the updated ConfluenceActionSupport_<KEY>.properties file (where <KEY> is the international language identifier), you should instead go to the Creating A New Confluence Translation.

To make small updates, it is quicker to translate the file directly. If your changes are more substantial, you may prefer to translate using Excel.

**Translating Directly**

This approach uses any file editor. If your translation uses English characters, you can skip to the next section.

**Preparing Non-Unicode Files For Direct Translation**

If you do not have the Sun Java JDK installed, please download it now. Version 5.0 can be downloaded here.

1. Create a script or batch file that uses the native2ascii.exe program bundled in <JAVA-JDK-DIRECTORY>/bin to convert from the natively encoded file back to the Unicode file. For example, update the Russian properties file with a script or batch file that calls native2ascii -encoding cp1251 JiraWebActionSupport_ru_RU-native.txt JiraWebActionSupport_ru_RU.properties

2. Copy ConfluenceActionSupport<KEY>.properties to a new file ConfluenceActionSupport<KEY>-native.txt. Save the new file local non-Unicode character encoding.

**Performing Direct Translation**

These steps apply to both Unicode and non-Unicode translations:

1. Open the properties file (or it's natively encoded equivalent) for editing, translate some or all of the properties file into your target language, and save the changes. If you are translating into a non-Unicode language, always edit ConfluenceActionSupport<KEY>-native.txt, otherwise modify ConfluenceActionSupport<KEY>.properties.

2. Edit the file content in a text editor, referring to Translating ConfluenceActionSupport Content for more information on how to modify the string values. Users who are unsatisfied with simply opening two copies of the file in their favourite editor may want to try this freeware properties editor, that allows side-by-side comparisons.

3. For non-Unicode translations only, run the native2ascii script to update native2ascii ConfluenceActionSupport<KEY>.properties

4. If you wish to test the update, copy the file back to its original location in the plugin. Then restart Confluence.

**Translating Using A Spreadsheet**

The guide below uses the open-source ExcelBundle, released under the Apache License 2.0. To translate from Excel or OpenOffice:

1. Unzip excelbundle0.9.zip to your local drive.

2. Browse to your Confluence install and go to the \confluence\WEB-INF\classes\com\atlassian\confluence\core directory. Copy the ConfluenceActionSupport.properties file there into the translation_tool directory and rename it to ConfluenceActionSupport_en.properties.

3. If you want to start a fresh translation, skip this step. To work from an existing translation, copy it into the translation_tool directory and remove any country variant from the filename, eg ConfluenceActionSupport_ru_RU.properties becomes ConfluenceActionSupport_ru.properties.

4. Call the translation tool to create the spreadsheet file. For example, to create a Russian translation, open a terminal window in the translation_tool directory and call java -jar excelbundle.jar -export translation_ru.xls -l en,ru -r "%cd%"

5. Edit the file content, referring to Translating ConfluenceActionSupport Content for more information on how to modify the string values.

6. Call the translation tool to export the updates back into the localised properties file. For the example Russian translation, open a terminal window, go to the translation_tool directory and call java -jar excelbundle.jar -import translation_ru.xls -l ru -r "%cd%"

7. Once you have completed editing, you must copy and rename the localised translation back to the language plugin directory. For frequent updates, you may wish to create a script to do this.

8. To view the updates after copying across the new properties file, select the language plugin for your translation, then restart Confluence and refresh your browser.
Lifecycle Plugins

Lifecycle plugin modules are available in Confluence 2.3 and later.

Lifecycle plugins allow you to perform tasks on application startup and shutdown.

- For more information about plugins in general, read Confluence Plugin Guide.
- To learn how to install and configure plugins (including macros), read Installing and Configuring Plugins Manually.
- For an introduction to writing your own plugins, read Writing Confluence Plugins

Application Lifecycle

Startup is performed after Confluence has brought up its Spring and Hibernate subsystems. If Confluence is being set up for the first time, the startup sequence is run after the completion of the setup wizard. This means that lifecycle plugins can assume access to a fully populated Spring container context, and a working database connection. (i.e. you don't need to check isContainerSetup() or isSetupComplete())

Shutdown is performed when the application server is shutting down the web application, but before the Spring context is disposed of.

Plugin Activation and Deactivation

Activating or deactivating a lifecycle plugin will not cause any of its lifecycle methods to be run. If you want your plugin to respond to activation and deactivation, you should make sure it implements Making your Plugin Modules State Aware.

Shutdown is not guaranteed

There are many situations in which the shutdown sequence will not be run, as it is dependent on the orderly shutdown of the application server. Plugins should not rely on shutdown being performed reliably, or even ever.

Shutdown lifecycle tasks are most useful for cleaning up resources or services that would otherwise leak in situations where the web application is being restarted, but the JVM is not exiting. (i.e. services that retain classloaders or threads that would otherwise prevent the application from being garbage-collected)

Defining a Lifecycle Plugin

Lifecycle plugin definitions are quite simple. Here’s a sample atlassian-plugin.xml fragment:

```xml
<lifecycle key="frobozz" name="Probozz Service" class="com.example.frobozz.Lifecycle" sequence="1200">
  <description>Start and stop the Probozz service</description>
</lifecycle>
```

- The key is the required plugin module key, which must be unique within the plugin.
- The name is the required display name for the plugin.
- The class is the required class name for the lifecycle service implementation.
- The sequence number is required, and determines the order in which lifecycle plugins are run. On startup, they are run from lowest to highest sequence number, then in reverse order on shutdown.

Defining a Lifecycle Service Implementation

If you are implementing a new lifecycle service, you should implement com.atlassian.config.lifecycle.LifecycleItem:
However, for convenience, and to make it easy to plug in third-party lifecycle events that are implemented as servlet context listeners, lifecycle service classes can instead implement `javax.servlet.ServletContextListener` – the `contextInitialized()` method will be called on startup, and `contextDestroyed()` on shutdown.

Sequences

The sequence numbers of the lifecycle modules determine the order in which they are run. On startup, modules are run from lowest to highest sequence number, then on shutdown that order is reversed (first in, last out). As a general guideline:

<table>
<thead>
<tr>
<th>Sequence number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 - 500</td>
<td>Configuration tweaks and application sanity checks.</td>
</tr>
<tr>
<td>800</td>
<td>Database and configuration upgrades.</td>
</tr>
<tr>
<td>5000</td>
<td>Start/stop the Quartz scheduler</td>
</tr>
</tbody>
</table>

- If your startup lifecycle item has a sequence less than 800, you can't assume that the configuration or database schema are current
- If you have a sequence number greater than 5000, you must keep in mind that scheduled jobs (including Job Plugins) may run before you've started up, or after you've shut down.

Macro Plugins

Macros are Confluence code that can be invoked from inside a page by putting the name of the macro in curly brackets. Users of Confluence will be familiar with macros like `{color}` or `{children}` or `{rss}`. Thanks to the plugin system, it is easy to write and install new macros into a Confluence server.

- Created a new macro or looking for macros?
  Share your macros and find new plugins in the Confluence extensions space.

- For Simple Macros
  If you want to create a macro that just inserts some boiler-plate text or performs simple formatting, you may only need a User Macro. User macros can be written entirely from within the Confluence web interface, and require no special installation or programming knowledge.

- Creating a macro for Confluence 3.0?
  Make it look good in the macro browser!

- Looking for a tutorial?
  Try this one

Adding a macro plugin

```java
package com.atlassian.config.lifecycle;

public interface LifecycleItem {

    /**
     * Called on application startup.
     *
     * @param context the application's lifecycle context
     * @throws Exception if something goes wrong during startup. No more startup items will be run, and the application will post a fatal error, shut down all LifecycleItems that have run previously, and die horribly.
     */
    void startup(LifecycleContext context) throws Exception;

    /**
     * Called on application shutdown
     *
     * @param context the application's lifecycle context
     * @throws Exception if something goes wrong during the shutdown process. The remaining shutdown items will still be run, but the lifecycle manager will log the error.
     */
    void shutdown(LifecycleContext context) throws Exception;
}
```
Macros are a kind of Confluence plugin module.

- For more information about plugins in general, read Confluence Plugin Guide.
- To learn how to install and configure plugins (including macros), read Installing and Configuring Plugins Manually.
- For an introduction to writing your own plugins, read Writing Confluence Plugins

**First steps: Creating a very basic plugin**

Make sure you have created your first macro plugin using our description over here. That will save you a lot of time.

**The next step: Understanding a slightly more realistic macro plugin**

The WoW plugin is a fun side-project created by Confluence developer Matthew Jensen. It loads information about World-of-Warcraft from a remote server, renders it on a Confluence page, and uses JavaScript for a nice hover-effect. You should download the source and learn more about it on the WoW Macro explanation page.

**The Macro Plugin Module**

Each macro is a plugin module of type "macro", packaged with whatever Java classes and other resources (i.e. Velocity templates) that the macro requires in order to run. Generally, similar macros are packaged together into a single plugin, for ease of management. Here is an example atlassian-plugin.xml file

```xml
<atlassian-plugin name='Task List Macros' key='confluence.extra.tasklist'>
<plugin-info>
<description>Macros to generate simple task lists</description>
<vendor name='Atlassian Software Systems' url='http://www.atlassian.com'/>
<version>1.3</version>
</plugin-info>

<macro name='tasklist' class='com.atlassian.confluence.extra.tasklist.TaskListMacro' key='tasklist'>
<description>Creates a very simple task list, with user checkable tasks</description>
</macro>

<!-- more macros... -->
</atlassian-plugin>
```

The name of the macro defines how it will be referenced from the page. So if you define your macro as having name="tasklist", the macro will be called from the page as [tasklist].

**The Macro Plugin Module Implementing Class**

The class attribute of the macro defines what Java class will be used to process that macro. This is the class you need to write in order for the macro to function. It must implement the com.atlassian.renderer.v2.macro.Macro interface.

A more complete guide to writing macros can be found in Writing Macros.

**Using a Velocity Template**

To use a Velocity template to provide the output of your macro, see Rendering Velocity templates in a macro.

**Example Macro Plugins**

The source-code of a number of macros (some of which are already built and packaged with Confluence) can be found in the plugins directory of your Confluence distribution. You can modify these macros (consistent with the Confluence license). The most interesting macros to read if you're looking at writing your own are probably:

- tasklist – a simple macro that stores its state in a page's PropertySet
- userlister – a macro that works in combination with an event listener to list logged-in users
- livesearch – a macro that leverages Javascript and XMLHttpRequest in combination with an XWork plugin to handle the server-side interaction.
- graphviz – a macro that interacts with an external, non-Java tool

**RELATED TOPICS**

Plugin Tutorial - Writing Macros for Confluence

**Documenting Macros**

This document is for the notation guide only. Please also see updating macros for the Macro Browser.

The Confluence notation guide is the popup window that describes all the markup and macros available within a Confluence installation. Obviously, if a macro is installed, you will want it to also appear in the notation guide.
To do this you will need to:

1. Write a help file
2. Tell Confluence where to find that help file

Writing the Help File

The help file is a file containing a fragment of HTML. Your HTML will be inserted into a two-columned table, so you should provide a single table row with two columns. On the left-hand side, put usage examples of your macro. On the right hand side provide a description and sample output.

The file will be rendered through Velocity, which means useful things like $req.contextPath are available to you.

Here's an example of the help file used for the {note} macro:

```
<tr bgcolor=ffffff>
  <!-- The left-hand table cell should contain usage examples -->
  <td>  
    {note:title=Be Careful}<br />
    The body of the note here..<br />
    </note>
  </td>
  <!-- The right-hand cell describes the macro and its available arguments -->
  <td>  
    Prints a simple note to the user.
    <ul>
      <li><b>title:</b> - (optional) the title of the note.</li>
      <li><b>icon:</b> - (optional) if "false", don't display the icon.</li>
    </ul>
    The body of the note here.. $req.contextPath/images/icons/emoticons/warning.png
  </td>
</tr>
```

Configuring the help file in your macro

The help file is included in your macro as a plugin resource of type "velocity" and name "help". Here's the plugin definition of the note macro, including its help file:

```
<macro name='note' class='com.atlassian.confluence.extra.information.NoteMacro' key='note'>
  <description>Draws a note (yellow).</description>
  <resource type="velocity" name="help" location="templates/extra/layout/notemacro-help.vm">
    <param name="help-section" value="advanced"/>
  </resource>
</macro>
```

The "help-section" parameter is optional, and determines which section of the notation guide the macro will be documented in. The following sections are available (Note that regular wiki markup is also defined in here, so some sections like 'breaks' are unlikely to be appropriate for any real macro):

- **texteffects**: Macros that change the appearance of text contained within them (e.g. (color))
- **headings**: Macros that create headings within a page
- **breaks**: Macros related to line- or paragraph breaks, or rulers
- **links**: Macros related to links to other wiki or external content (e.g. {anchor})
- **lists**: Macros related to lists
- **images**: Macros for inserting or manipulating images within a page (e.g. {gallery})
- **tables**: Macros for forming static tables (e.g. (section) and (column))
- **advanced**: Macros for creating more complex structures in a page (e.g. (panel) or (info))
Macros for manipulating or displaying Confluence data (e.g. {children})

Macros for manipulating or displaying data from other systems (e.g. {rss})

Macros that do anything else (Try to avoid using this section)

If you don’t provide a help section, your macro documentation will appear in the “Macros” section of the notation guide. (This section only appears in the notation guide if it is needed).

**Updating macros for the Macro Browser**

The Macro Browser is a new feature in Confluence 3.0, helping users to browse and insert macros while adding/editing content. If you are a plugin author, you may want to update your macro so it makes use of the new Macro Browser framework.

**Default macro display**

Even without updating your plugin, macros will be available in the Macro Browser’s ‘All’ category. As demonstrated in the screenshot below, the vote macro is available with its description displayed.

The insert macro screen will then display:

- a single input field for the parameters
- body text field (only if the macro returns true for `hasBody()`)
- notation help for the macro (only if available)

**Updating your macro**

However, you may want to update your macro so it behaves correctly in the macro browser and displays the correct parameter input fields. This will require simple changes to your macro definition in the atlassian-plugin.xml file. All of the bundled macros in Confluence 3.0 have been updated in this way.

**New Macro Descriptor Attributes**

The following are new macro attributes introduced for the macro browser.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>documentation-url</td>
<td>The absolute url to the macro's documentation.</td>
<td></td>
</tr>
</tbody>
</table>
| icon          | The relative url to the application for the macro icon.  
Note: if you have your icon defined as a downloadable resource, you can refer to this by specifying "download/resources/PLUGIN_KEY/RESOURCE_NAME" as the icon attribute. |         |
| hide-body     | This attribute is available for macros that falsely declare that they have body (most likely cause they extend BaseMacro) when they don’t.  
For example the gallery macro. This attribute helps hide the body text field in the macro browser. | false  |
| hidden        | If set to true, the macro is not visible in the macro browser for selection. Plugin authors may want to hide macros that are for their plugin’s internal use and shouldn’t really be used by users. Note that the parameter does not stop people from inserting a macro via the normal editor though. | false  |

**New Macro Elements**

The following are new macro elements introduced for the macro browser. They should be placed inside your `<macro>` element.
<table>
<thead>
<tr>
<th>Name</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>category</td>
<td></td>
<td>The category the macro should appear in. Valid categories are listed below.</td>
</tr>
<tr>
<td>alias</td>
<td></td>
<td>Defines an alias for the macro. This means that the macro browser will open for the defined aliases as if it were this macro. For example if <code>dynamictasklist</code> is an alias of <code>tasklist</code>, editing an existing <code>dynamictasklist</code> macro will open it as a <code>tasklist</code> macro.</td>
</tr>
<tr>
<td>parameters</td>
<td>✓</td>
<td>Defines a group of parameter elements. See example below.</td>
</tr>
<tr>
<td>parameter</td>
<td></td>
<td>This defines a single macro parameter. It must be an element of the parameters element. Its contents are described below.</td>
</tr>
</tbody>
</table>

**Macro Categories**

The following categories for macros have been defined (see `MacroCategory.java`). A macro with no category will show up in the default 'All' category.

- formatting
- confluence-content
- visuals
- navigation
- external-content
- communication
- reporting
- admin
- development

**Parameter Options**

Each `<parameter>` element must have the following attributes:

- **name** - A unique name of the parameter, or '' for the default (unnamed) parameter.
- **type** - The type of parameter. Currently the following parameter types are supported in the macro browser's UI:
  - boolean
  - enum
  - string (this is the default if unknown type)

These are optional:

- **required** - whether it is a required parameter, defaults to 'false'
- **multiple** - whether it takes multiple values, defaults to 'false'
- **default** - the default value for the parameter

It can also have the following optional child elements:

- `<alias name="xxx"/>` - alias for the macro parameter
- `<value name="xxx"/>` - describes a single 'enum' value - only applicable for enum typed parameters

**Example**

The following is an example of the Recently Updated Macro defined:
Note that this example contains parameter types which aren’t all supported in the macro browser UI, but may be in future releases.

Macro Icon Example

To provide an icon for your macro -
1) Create a resource for icons/images if you don’t already have one. e.g.

```
<resource key="icons" name="icons/" type="download" location="myplugin/images/icons"/>
```

This must be a top level resource in your atlassian-plugin.xml and must be defined before the macro.

2) Ensure your plugin should contain the resource directory myplugin/images/icons

3) Set the icon attribute on the macro e.g.

```
icon="/download/resources/pluginkey/icons/iconfile.png"
```

i18n Conventions

Instead of having to define i18n keys for each element in the macro definition, the following convention is used to lookup i18n keys for the macro browser.

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>{pluginKey}.{macroName}.label</td>
<td>Macro label/display name</td>
</tr>
<tr>
<td>{pluginKey}.{macroName}.desc</td>
<td>Macro description</td>
</tr>
<tr>
<td>{pluginKey}.{macroName}.param.{paramName}.label</td>
<td>Macro parameter label</td>
</tr>
<tr>
<td>{pluginKey}.{macroName}.param.{paramName}.desc</td>
<td>Macro parameter description</td>
</tr>
<tr>
<td>{pluginKey}.{macroName}.body.label</td>
<td>Macro body label (defaults to ‘Body Text’ if not provided)</td>
</tr>
<tr>
<td>{pluginKey}.{macroName}.body.desc</td>
<td>Macro body description</td>
</tr>
</tbody>
</table>

You will need to place the keys in a .properties file with a resource of type i18n in your plugin.

**User Macros**

User macros allow you to create simple formatting macros using the Confluence web interface.
User Macro Plugins and Macro Plugins

If you want to distribute your user macro as a plugin, please see User Macro Plugins. If you want to create more complex, programmatic macros in Confluence, you may need to write a Macro Plugin. Note also that Macro Plugins and User Macro Plugins can appear in the Confluence Notation Guide, whereas User Macros do not. Here is an example of the Confluence Notation Guide.

You need to have System Administrator permissions in order to create user macros.

On this page:

- Creating a User Macro
- Examples
  - Example 1: User Macro to Create a Red Box
  - Example 2: User Macro to Display "Hello World"
  - Example 3: User Macro to Demonstrate the Use of Parameters
- Available Objects
- User Macro Library

Creating a User Macro

To create a user macro,

1. Go to the 'Administration Console' and click 'User Macros' in the left-hand panel.
2. Click 'Create a User Macro' at the top of the list of macros.
3. Supply the information in the input fields as explained below, then click the 'Save' button.

Screenshot: Creating a User Macro

Input fields:

- 'Macro Name' — Enter the text that you will type, within curly brackets, to invoke the macro from within a page. For example, to invoke the 'floatright' macro defined in the above screenshot, you would type:

```plaintext
{floatright}
```

- 'Macro has a body' — Check this box if you will pass body-text to the macro when you invoke it from within a page, e.g.:
If you select 'Macro has a body', anything the user types within the body of the macro will be available in the macro in the $body variable. The options below allow you to tell Confluence to pre-process the body before it is placed in the macro output:

- **Use unprocessed macro body** — The body of the macro will be output exactly as entered, including any HTML markup. For example if the macro body is `<b>body</b>`, it will be displayed as `<b>body</b>` in the page.
- **Escape HTML in macro body** — The body of the macro will be output with HTML markup escaped. So if the macro body is `<b>body</b>`, it will be displayed as `<b>body</b>` in the page.
- **Convert macro body wiki markup to HTML** — The body of the macro will be converted from wiki text to HTML markup. So if the macro body is `*body*`, it will be displayed as `<span style="color: red">body</span>` in the page.

**'Output'** — Choose one of the following options:

- **'Macro generates HTML markup'** — Choose this if you wish to write your Template in HTML markup (as shown in the above screenshot).
- **'Macro generates wiki markup'** — Choose this if you wish to write your Template in wiki markup.
- **'Template'** — This specifies what the macro will do. Write this using the Velocity templating language. Here is more information on the Velocity project.

Note: If you ticked *Macro has a body*, your template can refer to the body-text by specifying $body.

**Examples**

**Example 1: User Macro to Create a Red Box**

As an example, let's write a simple macro that simply creates a red box (using an existing Confluence style) around some text (useful for writing about error conditions for example - hence the macro name 'error').

After clicking "New User Macro", enter `error` as the Name of your macro, and then put the following in the Template text area:

```html
<div class="errorbox">$body</div>
```

Then click Add. You should now see your new macro in the User Macros library, and you can now enable and disable it individually. To use the macro within a page, you would add notation like:

```
{error}This is bad{error}
```

And your page would (magically!) have an error box on it, like so:

This is bad

**Example 2: User Macro to Display 'Hello World'**

Take a look at an example of a 'Hello World' macro.

**Example 3: User Macro to Demonstrate the Use of Parameters**

This example demonstrates how you can pass parameters into your macro. Let's say you want to write your own font colour macro:

```
<span style="color: $param0">$body</span>
```

The usage of this macro would be:

```
{colour:red}Some example text{colour}
```

which will produce:

Some example text

If your macro requires more than one parameter, you can use variables $param0 to $param9 to represent them. To specify multiple parameters, use:
Where red, blue and green are the 1st, 2nd and 3rd parameters respectively.

Alternatively, you can also use explicitly named parameters in your macro. These macro parameters will appear as variables with the name $param<x>$ where <x> is the name of your parameter. To specify named parameters, use:

```
$param<name>
```

In your user macro you can then use $paramcolour which will have the value red in this case.

### Available Objects

The user macro above uses the $body object, which is available for use within your user macro template if the macro has a body.

You can pass parameters to your user macro in the same way as any other macro, separated by the pipe | sign. These parameters are provided to your template as param1, param2, ... paramN.

The complete list of objects available for use are:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Doc Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>$body</td>
<td>The body of the macro (if the macro has a body)</td>
<td></td>
</tr>
<tr>
<td>$param0-n</td>
<td>The parameters passed to your macro (as available)</td>
<td></td>
</tr>
<tr>
<td>$param&lt;name&gt;</td>
<td>Named parameters passed to your macro (as available)</td>
<td></td>
</tr>
<tr>
<td>$config</td>
<td>The BootstrapManager object, useful for retrieving Confluence properties</td>
<td>BootstrapManager</td>
</tr>
<tr>
<td>$content</td>
<td>The current ContentEntity object that this macro is a included in (if available)</td>
<td>ContentEntityObject</td>
</tr>
<tr>
<td>$space</td>
<td>The Space object that this content object is located in (if relevant)</td>
<td>Space</td>
</tr>
<tr>
<td>$generalUtil</td>
<td>A GeneralUtil object, with useful utility methods for URL encoding etc</td>
<td>GeneralUtil</td>
</tr>
<tr>
<td>$action</td>
<td>A blank ConfluenceActionSupport object, useful for retrieving i18n text if needed</td>
<td>ConfluenceActionSupport</td>
</tr>
<tr>
<td>$webwork</td>
<td>A VelocityWebWorkUtil object, for its htmlEncode() method</td>
<td>VelocityWebWorkUtil</td>
</tr>
<tr>
<td>$req</td>
<td>The current HttpServletRequest object (if the page is rendered as a result of an HTTP request)</td>
<td>HttpServletRequest</td>
</tr>
<tr>
<td>$res</td>
<td>The corresponding HttpServletResponse object (not recommended to be played with)</td>
<td>HttpServletResponse</td>
</tr>
<tr>
<td>$userAccessor</td>
<td>For retrieving users, groups and checking membership</td>
<td>UserAccessor</td>
</tr>
<tr>
<td>$permissionHelper</td>
<td>For determining user rights</td>
<td>PermissionHelper</td>
</tr>
</tbody>
</table>

**Velocity Context in Exporters**

The above context is not inherited by the Velocity context created for PDF or Word exports. To see the available objects in that context, see this page.

Normally, a parameter like $param2 that is missing will appear as "$param2" in the output. To display nothing when a variable is not set, use an exclamation mark after the dollar sign like "$!param2".

You can read more about object usage in the Velocity Template Overview.

### User Macro Library

Below is a list of existing user macros, written by other Confluence users. If you wish, you can install these on your Confluence site.

**Be careful when installing user macros from unknown authors**

- **Popup when over page element** — Allows to create a popup for adding a word definition or anything else
- **Show Page Name as Link** — Shows the page name as a link.
There are two ways to write a macro:

1. **Side Toggle User Macro** — This user macro embeds an expandable table column, which means expandable side bar. It is extended from **Expand Test User Macro**.
2. **Space access** — Shows the users who has access permissions.
3. **umc-link-window css style-able link macro** — Limited alternative to [link-window] supporting css style reference for link that pops up in new window
4. **User Activity** — Display a table of user activity for a space.
5. **Add Tool Tip to Normal Text** — Display tool tip over hovered text.
6. **Automatically label news post** — Automatically labels news post items by the desired label (or labels).
7. **Bookmark Icons** — displays an icon toolbar to link the current page on del.icio.us, Digg and other bookmarking services.
8. **Calling Attention to Page Content** — Sometimes, there is content on your page that you want people to see but you want to reference it elsewhere on your page. The {callattention2} macro makes this an easy 2 step process.
9. **Count pages in space** — Automatically counts the number of pages in the space.
10. **Create link with underline only on hover** — Display underline for link only when hovering.
11. **DailyMotion user macro** — Allows users to easily embed DailyMotion videos within Confluence
12. **Display trackback** — Display all trackbacks of current page.
13. **Drop Shadows User Macro** — Automatically add cross-browser, cross-platform drop-shadows to your panels...
14. **editable user macro**
15. **edit-include user macro** — Creates an seperately editable subsection of a page by implementing (include), (link-to) and (link-page) macros. A user macro workaround.
16. **Escape User Macro**
17. **Expand Text User Macro** — This user macro embeds an expandable text box into your page.
18. **Flash Video user macro** — Allows users to embed flv videos within Confluence
19. **Font Size** — Change the font size
21. **icq-time User macro** — Displays an ICQ user's local time using a groovy animated Flash widget...
22. **include_permissionchecked user macro** — When including a page where user has no permission to view you get an ugly red error hint
23. **Indent User Macro** — Easily indent content
24. **Install Search Engine user macro** — Add a link allowing to install a OpenSearch engine in your browser.
25. **Link to this page name in a different space** — Link to a page of this page's name in a specific space.
26. **Link with colour** — Display a link in a different colour.
27. **MacroDocumentation user macro** — Easily explain your usermacros to your authors how to use with code example and rendered view.
28. **Mailto User Macro** — Renders a block of text as a mailto, using urlencode to convert spaces and newlines properly.
29. **New Window User Macro** — Make links open in a new window
30. **No-Export macro** — A simple user macro to prevent the enclosed text from being exported to PDF, Word of HTML. Particular useful exported manuals or documentation.
31. **no-include User Macro**
32. **nomarkup macro** — Render plain text with no wiki markup notation
33. **Obfuscate email addresses** — Obfuscate email addresses on public pages using javascript
34. **Page Title Style** — Apply custom style to the page title.
35. **Profile Image Macro** — This user macro can be used to insert a user profile image or space logo easily into any Confluence page.
36. **Related Content User Macro** — A simple user macro to automatically generate related content based on the labels on the page. This macro wraps the (content-by-label) macro, pulling the labels directly from the page. If no labels are specified, the macro simply doesn't render anything.
37. **Rich Text Editor in Scaffolding** — Enable the Rich Text Editor in your Scaffolding textareas.
38. **Round Rectangle Macro** — Macro for creating rounded rectangles
39. **Show Page Source Inline Macro** — Display the source code of your page within the page itself. Helpful for showcasing your wiki coding mastery.
40. **Show the content ID (page ID) in a page** — Allows display of the page's Content ID - the unique ID field of the page.
41. **Show-to User Macro** — The show-to-authenticated and show-to-anonymous user macros provide a quick way to show content to only authenticated or anonymous users. **(OBSOLETE)**
42. **Space List Pulldown Menu** — Creates a pulldown menu of spaces based on a given tag
43. **space-permissions user macro** — Creates a summary table for the permissions assigned to the current space.
44. **Spaces listed by label** — List all Spaces (Name and Link) by a defined space label (if exists).
45. **SVG Image Macro**
46. **SVG Image User Macro** — A simple user macro to embed scalable vector graphics in wiki pages. You need to install a browser plugin, such as Adobe, to get it to work.
47. **Team Macro** — create a formatted table of users
48. **Twitter** — shows the latest three twitter posts
49. **Typewriter text effect - User Macro** — This user macro allows you to add a typewriter text effect to your content, adding one letter at a time until the text is fully displayed.
50. **Under construction macro** — Simple macro to warn people a page is being worked on
51. **User Macro Snippets** — Snippets, tools and standards for writing user macros
52. **User Profile Quick Jump Macro** — Allows to quick jump to a user profile based on its id.
53. **Version Macro** — Allows to display the current version of the page.
54. **Video and Audio Embed Macro With Autoplay Disabled**
55. **Word to Confluence Converter**
56. **youtube macro** — Allows users to easily embed YouTube videos within Confluence

**Hello World Example of User Macro**

There are two ways to write a macro:
• The first way is to create a **user macro**. You need to be a Confluence Administrator to do this. Below is an example.

### Example of a User Macro

Here’s how you can create a user macro which displays the text 'Hello World : ' in front of any variable text you place between the macro tags.

1. Go to the **Administration Console** and click **User Macros** under **Configuration** in the left-hand panel.
2. Click **Create a User Macro** at the top of the list of macros.
3. Enter the macro attributes as shown in the following screenshot.
4. Click the **Save** button.

- **Macro Name:** helloworld
- **Macro has a body:**
- **Output:** Macro generates HTML markup
- **Template:** Hello World : $body

So, now you can add the following Wiki Markup on your Confluence page:

```
{(helloworld)Matthew{(helloworld)
```

And the result will be as follows:

```
Hello World : Matthew
```

More Information

The macro itself is written in the Velocity Templating Language. You can find more information in the [Velocity User Guide from Apache](http://velocity.apache.org/).

**Wow Macro explanation**

**Skullspliter Helm**

*Birds when equipped*  
Head  
196 Armor  
+12 Stamina  
+11 Agility  
Requires Level 38

Item display is courtesy [www.allakhazam.com](http://www.allakhazam.com).

**Overview**

To flesh out the example macros, and to learn a bit about the process myself, I wrote a macro to insert World of Warcraft item links into any Confluence page. If you're not familiar with World of Warcraft (or WoW for those in-the-know) it's a MMORPG with millions of players world wide. What better way to show off some CSS and JavaScript integration with Confluence!

First a quick overview of what the macro is trying to do. If you've ever played the game or read any of the many WoW community web sites you would be familiar with item links. Each item in WoW has several properties that describe its use, its impossible to memorize the thousands of different items, so these web sites use javascript to add a popup to display item's details. When you move the mouse over the link the popup appears, showing you the details of the item. This example shows a link to the **Skullspliter Helm**.

The macro works by sending a message to Allakhazam's XML interface which is validated and parsed into an object. The Macro then uses a velocity template to generate a small snippet of HTML and with some jQuery JavaScript wizardry, produces a popup.

**The Plugin**

The World of Warcraft plugin consists of two parts: **The Macro**, and **The Web Resources**.

**The Macro**

The heart of any macro is the `execute` method. This method is responsible for returning the result of the macro's function, either in HTML or in WikiMarkup.

This macro goes through a very predictable process:

1. Validate and interpret the parameters
2. Connect to Allakhazam and ask for the item details
3. Use velocity to render the output

For the complete source take a look [here](http://www.allakhazam.com).

**Validate The Input**

We have some very simple requirements for input. We only have one parameter which is the item id. To confirm with what Allakhazam uses, I chose to call this parameter `witem`. I also wanted to allow the user to supply the parameter without a name. The process to do this is described briefly [here](http://www.allakhazam.com).

```
String witemString = (String) params.get("0");
if (witemString == null)
{
    witemString = (String) params.get("witem");
}
if (witemString == null)
{
    return "No witem specified."
}
int witem;
try
{
    witem = Integer.parseInt(witemString);
}
catch (NumberFormatException e)
{
    return "witem specified is not a number: "+witemString;
}
```

This code shows the process to check for the named and unnamed parameters (using the unnamed as preference). The string value is then validated by trying to convert to an integer.

**Connect to Allakhazam**

Now that we have a valid integer, that is hopefully valid item id, we use the `HttpRetrievalService` to send a HTTP request to the Allakhazam website.
For the macro to have access to the `HttpRetrievalService` all we need is a setter method named appropriately. Confluence will call this method at the appropriate time, you can do this to inject any of the Confluence components.

```java
private HttpRetrievalService httpRetrievalService;
public void setHttpRetrievalService(HttpRetrievalService httpRetrievalService)
{
    this.httpRetrievalService = httpRetrievalService;
}
```

The `HttpRetrievalService` takes care of the http connection for us and will time out according to the settings in the Administration section of the Confluence system. The retrieval service will give us an `InputStream` as the result so we need to read that and create an object which we can actually use.

The result from Allakhazam is in XML format, and its usually pretty small. I chose to use a DOM parser process the XML then a series of XPath queries to extract the details we wanted:

```java
HttpResponse response = httpRetrievalService.
    get("http://wow.allakhazam.com/cluster/item-xml.pl?witem=" + witem);
if (response.getStatusCode() != 200)
{
    return "error " + response.getStatusCode() + " loading item";
}
```

Allakhazam's XML format includes item details that match other locales, an extension to this plugin could use this information to provide the popup in the current user's locale!

### Render the Output

This macro uses velocity to render the output. This is helped using the `VelocityUtils` class which provides easy to use methods for accessing the Velocity subsystem.

```java
VelocityContext contextMap = new VelocityContext(MacroUtils.defaultVelocityContext());
contextMap.put(BODY_FIELD, item.getHtml());
contextMap.put(NAME_FIELD, item.getName());
contextMap.put(LINK_FIELD, "http://wow.allakhazam.com/db/item.html?witem=" + witem);
contextMap.put(QUALITY_FIELD, item.getQualityName());
return VelocityUtils.getRenderedTemplate(TEMPLATE_NAME, contextMap);
```

We first create a context map by calling `MacroUtils.defaultVelocityContext()`. This creates a `Map` of some useful components for our template rendering. Creating a context like this is important if you want to access macro's and other components supplied by Confluence. This example then places this map into a `VelocityContext` object to provide type safety on the put methods.

The template used by this macro is extremely simple.
Confluence 3.0 Documentation

The references to $qualityName, $link, $itemName, and $body are resolved by Velocity as the template is processed. They are looked up in the context we supplied in the macro.

The two requireResource calls tell Confluence to include the required resources in the page.

The first call tells Confluence to include jQuery. jQuery is actually available on every Confluence page, but since our macro uses it, we need to make sure Confluence loads jQuery first. We do that by supplying an explicit dependency in the order in which we need it.

These resources are configured in the atlassian-plugin.xml file inside the plugin.

This snippet of the configuration shows the definition of the resources this macro uses. Confluence will use the extension of the name attribute to work out how to link in the resource (ie: link or script tag).

We have two resources, one for the CSS and one for our JavaScript.

Resources

The web resources configured in the previous section contain the CSS formatting and JavaScript behavior of the macro. The CSS file is simple enough and can be seen here. Most of this CSS was taken from the Allakhazam web site then customized to work within Confluence. To do this I added a parent div tag to reduce the scope of the css selectors.

The JavaScript code uses jQuery to provide mouse over and popup functionality over the item link:

First, we a hook into the hover event on any element with the wow-link class. As the mouse enters over the link, the next sibling with the wowitem class will be shown. As the mouse leaves, its hidden. This turns the item information section on and off.

Another hook is added on the mouse move event while the pointer is over the link. This hook is used to move the popup with the mouse pointer.

The Result

You can download this plugin from here and install it through the Administration section of your 2.8.x Confluence instance.

The source is available here.

Compiling the Source

The general details of compiling a plugin applies to this plugin, so follow the instructions there.

For the impatient:

1. Install JDK 1.5 or later
2. Install Maven 2
3. Create a settings.xml file (a good start is this one)
4. Checkout the trunk or a tag of the source
5. use maven to compile it: mvn clean package

Writing Macros

Macros are written and deployed into Confluence as Macro Plugins. This page describes how to write a macro (but not how to get the plugin working, refer to the other page for that).
First steps

Make sure you have created your first macro plugin using our description over here. That will save you a lot of time.

The Macro Class

All macros must implement the `com.atlassian.renderer.v2.macro.Macro` interface. The Javadoc comments are probably the best place to start:

**The BaseMacro class**

While it's not a requirement, your macro should extend the `com.atlassian.renderer.v2.macro.BaseMacro` abstract class. This class does not contain any functionality, but if the `Macro` interface changes in the future, the `BaseMacro` class will be maintained in order to ensure backwards compatibility with existing macros.

Writing Your Macro

When writing a macro, you will need to override the following methods:

<table>
<thead>
<tr>
<th>Method</th>
<th>Should return...</th>
</tr>
</thead>
<tbody>
<tr>
<td>hasBody()</td>
<td>true if this macro expects to have a body, false otherwise</td>
</tr>
<tr>
<td>getBodyRenderMode()</td>
<td>The <code>RenderMode</code> under which the body should be processed before being passed into the macro</td>
</tr>
<tr>
<td>isInLine()</td>
<td>false if the macro produces a block element (like a paragraph, table or div) true if it is inline and should be incorporated into surrounding paragraphs</td>
</tr>
<tr>
<td>execute()</td>
<td>a fragment of HTML that is the rendered macro contents</td>
</tr>
</tbody>
</table>

Understanding `RenderMode`

The `RenderMode` tells the Confluence wiki renderer which wiki-conversion rules should be applied to a piece of text. Once again, the best place to start is the Javadoc:

There are a number of pre-defined render modes. The ones that would be useful to macro writers are probably:

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RenderMode.ALL</td>
<td>Render everything</td>
</tr>
<tr>
<td>RenderMode.NO.Render</td>
<td>Don't render anything; just return the raw wiki text</td>
</tr>
<tr>
<td>RenderMode.INLINE</td>
<td>Render things you'd normally find inside a paragraph, like links, text effects and so on</td>
</tr>
<tr>
<td>RenderMode.SIMPLE_TEXT</td>
<td>Render text made up only of paragraphs, without images or links</td>
</tr>
</tbody>
</table>

If you want finer control, `RenderMode` is implemented as a bit-field. Each constant of `RenderMode` starting with `F_` is a feature of the renderer that can be turned on or off. You can construct a `RenderMode` by manipulating these bits through the following methods:

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>RenderMode.allow()</td>
<td>Allow only the renderings specified</td>
<td>`RenderMode.allow(RenderMode.F_LINKS</td>
</tr>
<tr>
<td>RenderMode.suppress()</td>
<td>Allow all renderings except those specified</td>
<td>`RenderMode.suppress(RenderMode.F_MACROS</td>
</tr>
<tr>
<td>and()</td>
<td>Perform a logical AND on an existing render mode</td>
<td><code>RenderMode.SIMPLE_TEXT.and(RenderMode.suppress(RenderMode.F_PARAGRAPHS) will render SIMPLE_TEXT without paragraphs</code></td>
</tr>
</tbody>
</table>
Many macros (like this note macro) produce a `div`. Often, if there's only one line of text within a `div`, you don't want it surrounded in paragraph tags. For this reason, the `RenderMode.F_FIRST_PARA` flag controls the first line of wiki text that is rendered. If `F_FIRST_PARA` is not set, and the first line of text is a paragraph, the paragraph tags will not be rendered.

How to determine the context your macro is being rendered in

One of the parameters to the `execute()` method, the one with type `RenderContext`, can be used to determine how the macro is being rendered. See the relevant Confluence Developer FAQ entry for the details.

Accessing the Rest of the System

Like all Confluence plugin modules, Macros are autowired by the Spring framework. To obtain a manager object through which you can interact with Confluence itself, all you need to do is provide a Javabeans-style setter method for that component on your `Macro` class. See Accessing Confluence Components From Plugin Modules

Advanced Macro Techniques

Macros are often most powerful when combined with other plugin modules. For example, the `{livesearch}` macro uses an XWork plugin to perform its server-side duties, and the `{userlister}` plugin uses a listener plugin to listen for login events and determine who is online. You may also consider using a component plugin to share common code or state between macros.

How Macros are Processed

If you want to know exactly what happens when a macro is processed, the following (slightly overly-detailed) description should help:

Consider the following code in a Wiki page:

```
{mymacro:blah|width=10|height=20}This _is_ my macro body{mymacro}
```

1. The `MacroRendererComponent` finds the first `{mymacro:blah|width=10|height=20}` tag, and asks the `MacroManager` if a macro is currently active with the name "mymacro". The `MacroManager` returns a singleton instance of your `Macro`.
2. The `MacroRendererComponent` calls `hasBody()` on the `Macro`.
   a. If `hasBody()` returns false, the macro is processed with a 'null' body, and the next (mymacro) tag will be processed as a separate macro.
   b. If `hasBody()` returns true, the `MacroRendererComponent` looks for the closing `{mymacro}`. Anything between the two becomes the macro body.
      i. If there is a macro body, the `MacroRendererComponent` then calls `getRenderMode()` on the macro to determine how that body should be rendered
      ii. The macro body is processed through the wiki renderer with the given RenderMode before being passed to the macro
3. The `MacroRendererComponent` calls `execute` on the macro, passing in the macro parameters, the (processed) body, and the current `RenderMode`
   • The `execute` method should return an HTML string. No further wiki processing is performed on macro output.
   • The parameters are a `Map` of `{{String}}`, keyed by parameter name.
     • If any parameter is not named, it is keyed by the string representation of its position: so for the above example, `parameters.get("0")` would return "blah".
     • `parameters.get(Macro.RAW_PARAMS_KEY)` will return the raw parameter string, in this case: `"blah|width=10|height=20"
4. The `MacroRendererComponent` calls `isInline()` on the macro to determine if its results should be inserted into the surrounding page as an inline (i.e. part of a surrounding paragraph) or a block element.

Module Type Plugins

On this page:

- Purpose of this Module Type
- Configuration
  - Attributes
  - Elements
- Example
- Notes

Purpose of this Module Type

Module Type plugin modules allow you to dynamically add new plugin module types to the plugin framework, generally building on other plugin modules. For example, a plugin developer could create a `<dictionary>` plugin module that is used to feed a dictionary service used by still other plugins.
Configuration

The root element for the Module Type plugin module is `module-type`. It allows the following attributes and child elements for configuration:

Attributes

<table>
<thead>
<tr>
<th>Name</th>
<th>Required</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>class</td>
<td></td>
<td>The ModuleDescriptor class to instantiate when a new plugin module of this type is found.</td>
<td></td>
</tr>
<tr>
<td>disabled</td>
<td></td>
<td>Indicate whether the plugin module should be disabled by default (value='true') or enabled by default (value='false').</td>
<td>false</td>
</tr>
<tr>
<td>i18n-name-key</td>
<td></td>
<td>The localisation key for the human-readable name of the plugin module.</td>
<td></td>
</tr>
<tr>
<td>key</td>
<td>✔</td>
<td>The identifier of the plugin module. This key must be unique within the plugin where it is defined.</td>
<td>N/A</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Sometimes you will need to uniquely identify a module. Do this with the module complete key. A module with key fred in a plugin with key com.example.modules will have a complete key of com.example.modules:fred, i.e. the identifier of the module type. This value will be used as the XML element name to match.</td>
<td></td>
</tr>
<tr>
<td>name</td>
<td></td>
<td>The human-readable name of the plugin module.</td>
<td></td>
</tr>
<tr>
<td>system</td>
<td></td>
<td>Indicates whether this plugin module is a system plugin module (value='true') or not (value='false'). Only available for non-OSGi plugins.</td>
<td>false</td>
</tr>
</tbody>
</table>

Elements

<table>
<thead>
<tr>
<th>Name</th>
<th>Required</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>description</td>
<td></td>
<td>The description of the plugin module. The 'key' attribute can be specified to declare a localisation key for the value instead of text in the element body.</td>
<td></td>
</tr>
</tbody>
</table>

Example

Here is an example `atlassian-plugin.xml` file containing a plugin module type:

```xml
<atlassian-plugin name="Hello World" key="example.plugin.helloworld" plugins-version="2">
  <plugin-info>
    <description>A dictionary module type test</description>
    <vendor name="Atlassian Software Systems" url="http://www.atlassian.com"/>
    <version>1.0</version>
  </plugin-info>
  <module-type key="dictionary" class="example.plugin.DictionaryModuleDescriptor" />
</atlassian-plugin>
```

The Java code for `DictionaryModuleDescriptor` could look like this:

```java
public class DictionaryModuleDescriptor extends AbstractModuleDescriptor<Dictionary> {
  private String language;

  @Override
  public void init(Plugin plugin, Element element) throws PluginParseException {
    super.init(plugin, element);
    language = element.attributeValue("lang");
  }

  public Dictionary getModule() {
    return (Dictionary)((AutowireCapablePlugin)plugin).autowire(getModuleClass());
  }

  public String getLanguage() {
    return language;
  }
}
```
This will add the new module type ‘dictionary’ to the plugin framework, allowing other plugins to use the new module type. Here is a plugin that uses the new ‘dictionary’ module type:

```xml
<atlassian-plugin name="Hello World" key="example.plugin.helloworld" plugins-version="2">
  <plugin-info>
    <description>An english dictionary</description>
    <vendor name="Atlassian Software Systems" url="http://www.atlassian.com"/>
    <version>1.0</version>
  </plugin-info>
  <dictionary key="english" class="example.plugin.english.MyDictionary"/>
</atlassian-plugin>
```

Notes

Some information to be aware of when developing or configuring a Module Type plugin module:

- The plugin that defines a new module type cannot use the module type in the Plugin Framework 2.1, but can in 2.2 or later.
- If you want to have control over the construction of the ModuleDescriptor, you can skip the ‘module-type’ module and make public a component registered against the ModuleDescriptorFactory interface:

```xml
<component key="dictionaryFactory" class="example.plugin.DictionaryModuleDescriptorFactory" public="true">
  <interface>com.atlassian.plugin.ModuleDescriptorFactory</interface>
</component>
```

Ensure your ModuleDescriptorFactory implements

```java
com.atlassian.plugin.osgi.external.ListableModuleDescriptorFactory
```

RELATED TOPICS

Writing Confluence Plugins
Installing and Configuring Plugins Manually

Information sourced from Plugin Framework documentation

Path Converter Plugins

Path Converter plugin modules are available in Confluence 2.8 and later versions.

Path Converter plugin modules are useful for developers who are writing Confluence plugins. The Path Converter modules allow you to install custom path mapping as a part of your plugin.

- For more information about plugins in general, read the Confluence Plugin Guide.
- To learn how to install and configure plugins and macros, read Installing and Configuring Plugins Manually.
- For an introduction to writing your own plugins, read Writing Confluence Plugins.

The Path Converter Plugin Module

Each path converter can be used to map a friendly URL to an action either within Confluence or provided by your plugin. Here is an example

```xml
<atlassian-plugin name="Hello World Converter" key="confluence.extra.simpleconverter">
  <plugin-info>
    <description>Example Path Converter</description>
    <vendor name="Atlassian Software Systems" url="http://www.atlassian.com"/>
    <version>1.0</version>
  </plugin-info>
  <path-converter weight="10" key="example-converter" class="plugin.ExamplePathConverter"/>
</atlassian-plugin>
```

- The `<atlassian-plugin>` element specifies a class that implements
  `com.atlassian.confluence.servlet.simpledisplay.PathConverter`
- The `<version>` element defines when the path converter is executed in relation to the other converters. See Notes below.
- The `<key>` is the normal plugin module identifier.
Example

This converter is used by Confluence to convert the friendly /display/SpaceKey/PageTitle/ URL format into a request against the correct WebWork action.

```java
public class PagePathConverter implements PathConverter {
    private static final String DISPLAY_PAGE_PATH = "/pages/viewpage.action?spaceKey=${spaceKey}&title=${title}"

    public boolean handles(String simplePath) {
        return new StringTokenizer(simplePath, "/").countTokens() == 2;
    }

    public ConvertedPath getPath(String simplePath) {
        StringTokenizer st = new StringTokenizer(simplePath, "/");
        String spaceKey = st.nextToken();
        String pageTitle = st.nextToken();

        ConvertedPath path = new ConvertedPath(DISPLAY_PAGE_PATH);
        path.addParameter("spaceKey", spaceKey);
        path.addParameter("title", pageTitle);
        return path;
    }
}
```

The `handles` method is called (in order of weight) on each converter and the first to return `true` will have its `getPath` method called. The `getPath` method will convert the friendly path into a `ConvertedPath` object.

The `ConvertedPath` object expects a URL template and a series of parameters. It uses Velocity internally to merge the template and the parameters, producing a final URL.

Notes

The `com.atlassian.confluence.servlet.simpledisplay.SimpleDisplayServlet` will pass each incoming request that starts with `/display` to each of its configured converters. The converters will be checked starting with the converter with the lowest weight.

The PathConverters are autowired at registration time, so add a setter method on your converter to get access to Confluence's components.

```java
public class MyPathConverter implements PathConverter {
    private PageManager pageManager;

    // other methods

    public void setPageManager(PageManager pageManager) {
        this.pageManager = pageManager;
    }
}
```

Core Converters

Confluence includes a series of core path converters that are used to provide friendly URLs for standard Confluence resources.

<table>
<thead>
<tr>
<th>Weight</th>
<th>Core PathConverter</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>com.atlassian.confluence.servlet.simpledisplay.PagePathConverter</td>
</tr>
<tr>
<td>20</td>
<td>com.atlassian.confluence.servlet.simpledisplay.MailPathConverter</td>
</tr>
<tr>
<td>30</td>
<td>com.atlassian.confluence.servlet.simpledisplay.BlogPathConverter</td>
</tr>
<tr>
<td>40</td>
<td>com.atlassian.confluence.servlet.simpledisplay.UserPathConverter</td>
</tr>
<tr>
<td>50</td>
<td>com.atlassian.confluence.servlet.simpledisplay.SpacePathConverter</td>
</tr>
</tbody>
</table>

You can use any weight for your converter. If the same weight is used by multiple converters, they are executed in order of registration.

Renderer Component Plugins

Renderer Component plugin modules are available in Confluence 2.8 and later.
Renderer Component plugins allow you to add additional processors when converting wiki markup to HTML.

- For more information about plugins in general, read Confluence Plugin Guide.
- To learn how to install and configure plugins (including macros), read Installing and Configuring Plugins Manually.
- For an introduction to writing your own plugins, read Writing Confluence Plugins

**Warning**

This document concerns plugging renderer components into Confluence. The implementation of renderer components themselves is not documented.

Renderer component plugins were added to Confluence to make certain development tasks easier inside Atlassian. They are documented here for Atlassian developers, and for the sake of completeness, but we do not recommend customers add their own plugins to this area. The wiki markup rendering process is quite fragile, and simple changes can have wide-reaching effects.

In other words, you're on your own here.

**Defining a Renderer Component Plugin**

Here's a sample atlassian-plugin.xml fragment:

```xml
<renderer-component key="foo" name="Foo Renderer" class="com.example.frobozz.FooRendererComponent" weight="1000">
  <description>Convert foo markup to HTML</description>
</renderer-component>
```

- **The key** is the required plugin module key, which must be unique within the plugin.
- **The name** is the required display name for the plugin.
- **The class** is the required class name for the renderer component implementation.
- **The weight** number is required, and determines the order in which renderer component plugins are run over the wiki markup. Components are run from lowest to highest weights

**Implementing a Renderer Component Plugin**

The class referred to by the module descriptor must implement one of the following interfaces:

- `com.atlassian.renderer.v2.components.RendererComponent`
- `com.atlassian.renderer.v2.plugin.RendererComponentFactory`

This allows you to provide either a component directly, or a factory that can be used to instantiate more complex components. If you are using a factory, you can provide arbitrary parameters that will be passed to the factory when the component is instantiated:

```xml
<renderer-component key="foo" name="Foo Renderer" class="com.example.frobozz.FooRendererComponentFactory" weight="1000">
  <param name="animal">monkey</param>
  <param name="vegetable">lettuce</param>
  <param name="mineral">quartz</param>
</renderer-component>
```

These parameters will be passed into the factory's instantiate method as a Map<String, String>.

**RPC Plugins**

**Availability**

RPC plugin modules are implemented in Confluence 1.4 and later.

RPC plugins allow you to deploy arbitrary SOAP or XML-RPC services within Confluence. These services may be completely independent of Confluence, or may take advantage of the Confluence APIs to provide a remote, programmatic interface to the Confluence server. Confluence's packaged remote API is implemented entirely as a plugin.

- For more information about plugins in general, read Confluence Plugin Guide.
- To learn how to install and configure plugins (including macros), read Installing and Configuring Plugins Manually.
- For an introduction to writing your own plugins, read Writing Confluence Plugins
- The Remote API packaged with Confluence is documented at Remote API Specification

**XML-RPC Plugins**

Here is an example atlassian-plugin.xml file containing a single XML-RPC service:
the **class** attribute defines the class that will be servicing XML-RPC requests. One instance of this class will be instantiated, and all of its public methods will be made available remotely. The instance is autowired from the Spring context.

- the **service-path** attribute is the method-prefix that is used to determine which XML-RPC method calls are routed to this plugin.

Confluence listens for XML-RPC requests at a single end-point. If your server is deployed at `http://www.example.com` then all XML-RPC requests must be made to `http://www.example.com/rpc/xmlrpc`. As such, the service-path is used to distinguish which plugin each request is directed at. If your RPC implementing class has a method `provideGreeting()`, and a service-prefix of `helloworld`, then the XML-RPC method call will be `helloworld.provideGreeting()`.

### XML-RPC Interfaces

The XML-RPC specification is more limited than Java code. In particular:

- all method parameters in the class you have deployed must take as arguments, and return as values only the "XML-RPC-friendly types" listed below.
- `null` is not a valid XML-RPC type, so you must never send `null` as an argument, or return `null` as a value.
- `void` is not a valid XML-RPC return type, so all methods exposed via XML-RPC must return some value.

Valid types for use as arguments in methods exposed via XML-RPC, or as return values from XML-RPC methods are:

- `int`
- `boolean`
- `java.lang.String`
- `double`
- `java.util.Date`
- `java.util.Hashtable`
- `java.util.Vector`
- `byte[]`

The object wrappers for the primitive types (`java.lang.Integer`, `java.lang.Boolean`, etc) may be used as return values, but not as method arguments. For more information, see: `http://ws.apache.org/xmlrpc/types.html`

### SOAP Plugins

Here is an example `atlassian-plugin.xml` file containing a single SOAP service:

- the **class** attribute defines the class that will be servicing SOAP requests. One instance of this class is instantiated and autowired from the Spring context.
- the **service-path** element defines the SOAP service-path for this plugin, and where its WSDL file will be located.
- the **published-interface** element defines a Java interface that will be exposed via the SOAP service. The class defined in the **class** attribute must implement this interface.

Confluence listens for SOAP requests at a single end-point. If your server is deployed at `http://www.example.com` then all XML-RPC requests must be made to `http://www.example.com/rpc/soap`. The preferred method for calling a SOAP service on Confluence is by parsing the WSDL file that is generated automatically for any deployed SOAP plugin. If your plugin has a service-path of `helloworld`, its WSDL file will be available at `http://www.example.com/rpc/soap/helloworld.wsdl`
Unlike XML-RPC, SOAP can accept and return complex types.

**RPC Authentication**

Confluence supplies a very simple, token-based authentication service for its remote API. Users log in over the remote interface using a `login(username, password)` method, and are supplied with a String token. This String token is then supplied as the first argument of any subsequent remote call, to authenticate the user with their previous login. More information about this protocol can be found in the Remote API Specification documentation.

Any RPC plugin can take advantage of the authentication service. To do so you must make some changes to your remote service objects, and to the configuration.

Here is an `atlassian-plugin.xml` containing SOAP and XML-RPC services that require authentication:

```xml
<atlassian-plugin name="Sample XML-RPC" key="confluence.extra.xmlrpc">
  ...
  <rpc-xmlrpc key="helloworldsecure-xmlrpc" name="Secure Hello World XML-RPC">
    <description>An example XML-RPC service that requires a login</description>
    <service-name>helloworldPublic</service-name>
    <service-path>helloworld-secure</service-path>
    <authenticate>true</authenticate>
  </rpc-xmlrpc>
  ...
</atlassian-plugin>
```

An authenticated XML-RPC service requires an additional `published-interface` element that behaves like the `published-interface` element in the SOAP plugin: you must supply a Java Interface to represent which methods of your plugin class are being exposed remotely. The class represented by the `class` attribute must implement this interface.

There are two changes you have to make to your remote service objects (and their published interfaces) to allow them to take advantage of authentication:

1. You must implement the `String login(String username, String password)` and `boolean logout(String token)` methods in `com.atlassian.confluence.rpc.SecureRpc`. However, since these methods will be intercepted by the Confluence RPC framework, they will never actually be called on your object. As such, you can leave the implementations empty.
2. All methods in your published interface must have an initial argument that is a String (the authentication token). This token will also be intercepted by the Confluence RPC framework. Your code must not rely on this token having any value by the time the method is called on your plugin.

If you are providing an authenticated service, the logged-in User will be available to you from `com.atlassian.confluence.user.AuthenticatedUserThreadLocal.getUser()`

If anonymous RPC is enabled for your server, the logged-in user may be `null`.

**Hibernate Session**

If you use the Confluence API within your plugin you will probably need to create a Hibernate session, and start a transaction. Getting an error like `net.sf.hibernate.HibernateException: Could not initialize proxy - the owning Session was closed` is one indication.

Using the HelloWorld example above:

The class which implements your service needs to delegate each call to another object, which will be supplied when the HelloWorld instance is autowired.
HelloWorldDelegator contains the actual implementation of your service. It implements the same interface as HelloWorld, i.e. HelloWorldPublic. It is declared as a Spring bean, wrapped in a transaction:

```java
class HelloWorld implements HelloWorldPublic
{
    private HelloWorldDelegator helloWorldDelegator;

    public int doSomething(String arg)
    {
        return helloWorldDelegator.doSomething(arg);
    }

    public void setHelloWorldDelegator(HelloWorldHandler helloWorldDelegator)
    {
        this.helloWorldDelegator = helloWorldDelegator;
    }
}
```

Example

Example XML-RPC and SOAP plugins are available in the Confluence distribution under plugins/helloworldrpc. It can also be found [here](http://example.com).

The full source to the Confluence remote API plugin can be found in the Confluence distribution under plugins/confluencerpc. The Confluence Remote API uses a mixture of RPC plugins and Component Plugins, along with a simple mechanism to serialize Java objects into an XML-RPC compatible struct, to serve the same API over both SOAP and XML-RPC. We strongly recommend you use a similar mechanism to provide both RPC APIs.

Servlet Context Listener Plugins

On this page:
- Purpose of this Module Type
- Configuration
  - Attributes
  - Elements
- Example
- Notes

Purpose of this Module Type

Servlet Context Listener plugin modules allow you to deploy Java Servlet context listeners as a part of your plugin. This helps you to integrate easily with frameworks that use context listeners for initialisation.

Configuration

The root element for the Servlet Context Listener plugin module is `servlet-context-listener`. It allows the following attributes and child elements for configuration:

Attributes
### Name Required Description Default

<table>
<thead>
<tr>
<th>Name</th>
<th>Required</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>class</td>
<td>✓</td>
<td>The class which implements this plugin module. The class you need to provide depends on the module type. For example, Confluence theme, layout and colour-scheme modules can use classes already provided in Confluence. So you can write a theme-plugin without any Java code. But for macro and listener modules you need to write your own implementing class and include it in your plugin. The servlet context listener Java class. Must implement javax.servlet.ServletContextListener.</td>
<td></td>
</tr>
</tbody>
</table>

| disabled | ✓        | Indicate whether the plugin module should be disabled by default (value='true') or enabled by default (value='false'). | false   |

| i18n-name-key | ✓        | The localisation key for the human-readable name of the plugin module. |         |

| key | ✓        | The identifier of the plugin module. This key must be unique within the plugin where it is defined. Sometimes you will need to uniquely identify a module. Do this with the module complete key. A module with key fred in a plugin with key com.example.modules will have a complete key of com.example.modules:fred.i.e. the identifier of the context listener. | N/A     |

| name | ✓        | The human-readable name of the plugin module. i.e. the human-readable name of the listener. | true    |

| system | ✓        | Indicates whether this plugin module is a system plugin module (value='true') or not (value='false'). Only available for non-OSGi plugins. | false   |

### Elements

<table>
<thead>
<tr>
<th>Name</th>
<th>Required</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>description</td>
<td>✓</td>
<td>The description of the plugin module. The 'key' attribute can be specified to declare a localisation key for the value instead of text in the element body. I.e. the description of the listener.</td>
<td></td>
</tr>
</tbody>
</table>

### Example

Here is an example atlassian-plugin.xml file containing a single servlet context listener:

```xml
<atlassian-plugin name="Hello World Listener" key="example.plugin.helloworld" plugins-version="2">
  <plugin-info>
    <description>A basic Servlet context listener module test - says "Hello World!"</description>
    <vendor name="Atlassian Software Systems" url="http://www.atlassian.com"/>
    <version>1.0</version>
  </plugin-info>
  <servlet-context-listener name="Hello World Listener" key="helloWorld" class="com.example.myplugins.helloworld.HelloWorldListener">
    <description>Initialises the Hello World plugin.</description>
  </servlet-context-listener>
</atlassian-plugin>
```

### Notes

Some information to be aware of when developing or configuring a Servlet Context Listener plugin module:

- The servlet context you listen for will not be created on web application startup. Instead, it will be created the first time a servlet or filter in your plugin is accessed after each time it is enabled, triggering a new instance of your listener followed by the calling of the listener's contextCreated() method. This means that if you disable a plugin containing a listener and re-enable it again, the following will happen:
  1. The contextDestroyed() method will be called on your listener after the plugin was disabled.
  2. A new servlet context will be created after the plugin was re-enabled.
  3. Your listener will be instantiated.
  4. The method contextCreated() on your listener will be called.
 Purpose of this Module Type

Servlet Context Parameter plugin modules allow you to set parameters in the Java Servlet context shared by your plugin's servlets, filters, and listeners.

 Configuration

The root element for the Servlet Context Parameter plugin module is `servlet-context-param`. It allows the following attributes and child elements for configuration:

 Attributes

<table>
<thead>
<tr>
<th>Name</th>
<th>Required</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>class</td>
<td></td>
<td>The class which implements this plugin module. The class you need to provide depends on the module type. For example, Confluence theme, layout and colour-scheme modules can use classes already provided in Confluence. So you can write a theme-plugin without any Java code. But for macro and listener modules you need to write your own implementing class and include it in your plugin.</td>
<td></td>
</tr>
<tr>
<td>disabled</td>
<td></td>
<td>Indicate whether the plugin module should be disabled by default (value='true') or enabled by default (value='false').</td>
<td>false</td>
</tr>
<tr>
<td>i18n-name-key</td>
<td></td>
<td>The localisation key for the human-readable name of the plugin module.</td>
<td></td>
</tr>
<tr>
<td>key</td>
<td></td>
<td>The identifier of the plugin module. This key must be unique within the plugin where it is defined. A module with key fred in a plugin with key com.example.modules will have a complete key of com.example.modules:fred. I.e. The identifier of the context parameter.</td>
<td>N/A</td>
</tr>
<tr>
<td>name</td>
<td></td>
<td>The human-readable name of the plugin module. i.e. The human-readable name of the context parameter.</td>
<td></td>
</tr>
<tr>
<td>system</td>
<td></td>
<td>Indicates whether this plugin module is a system plugin module (value='true') or not (value='false'). Only available for non-OSGi plugins.</td>
<td>false</td>
</tr>
</tbody>
</table>

 Elements

<table>
<thead>
<tr>
<th>Name</th>
<th>Required</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>description</td>
<td></td>
<td>The description of the plugin module. The 'key' attribute can be specified to declare a localisation key for the value instead of text in the element body. i.e. the description of the listener.</td>
<td></td>
</tr>
<tr>
<td>param-name</td>
<td></td>
<td>The servlet context parameter name.</td>
<td>N/A</td>
</tr>
<tr>
<td>param-value</td>
<td></td>
<td>The servlet context parameter value.</td>
<td>N/A</td>
</tr>
</tbody>
</table>

 Example

Here is an example `atlassian-plugin.xml` file containing a single servlet context parameter:

```xml
<atlassian-plugin name="Hello World" key="example.plugin.helloworld" plugins-version="2">
  <plugin-info>
    <description>A basic Servlet context parameter module test</description>
    <vendor name="Atlassian Software Systems" url="http://www.atlassian.com"/>
    <version>1.0</version>
  </plugin-info>
  <servlet-context-param key="helloWorld">
    <description>Sets the Hello World text.</description>
    <param-name>text</param-name>
    <param-value>Hello World!</param-value>
  </servlet-context-param>
</atlassian-plugin>
```

 Notes
Some information to be aware of when developing or configuring a Servlet Context Parameter plugin module:

- This parameter will only be available to servlets, filters, and context listeners within your plugin.

Servlet Filter Plugins

On this page:

- Purpose of this Module Type
- Configuration
  - Attributes
  - Elements
- Example
- Accessing your Servlet Filter
- Notes

Purpose of this Module Type

Servlet Filter plugin modules allow you to deploy Java Servlet filters as a part of your plugin, specifying the location and ordering of your filter. This allows you to build filters that can tackle tasks like profiling and monitoring as well as content generation.

Configuration

The root element for the Servlet Filter plugin module is `<servlet-filter>`. It allows the following attributes and child elements for configuration:

Attributes

<table>
<thead>
<tr>
<th>Name</th>
<th>Required</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>class</td>
<td></td>
<td>The class which implements this plugin module. The class you need to provide depends on the module type. For example, Confluence theme, layout and colour-scheme modules can use classes already provided in Confluence. So you can write a theme-plugin without any Java code. But for macro and listener modules you need to write your own implementing class and include it in your plugin. The servlet filter Java class must implement javax.servlet.Filter.</td>
<td>N/A</td>
</tr>
<tr>
<td>disabled</td>
<td></td>
<td>Indicate whether the plugin module should be disabled by default (value='true') or enabled by default (value='false').</td>
<td>false</td>
</tr>
<tr>
<td>i18n-name-key</td>
<td></td>
<td>The localisation key for the human-readable name of the plugin module.</td>
<td>N/A</td>
</tr>
<tr>
<td>key</td>
<td>✓</td>
<td>The identifier of the plugin module. This key must be unique within the plugin where it is defined.</td>
<td>N/A</td>
</tr>
<tr>
<td>location</td>
<td></td>
<td>The position of the filter in the application's filter chain. If two plugins provide filters at the same position, the 'weight' attribute (see below) is evaluated.</td>
<td>before-dispatch</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• after-encoding - Near the very top of the filter chain in the application, but after any filters which ensure the integrity of the request.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• before-login - Before the filter that logs in the user with any authentication information included in the request.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• before-decoration - Before the filter which does decoration of the response, typically with Sitemesh.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• before-dispatch - At the end of the filter chain, before any servlet or filter which handles the request by default.</td>
<td></td>
</tr>
<tr>
<td>name</td>
<td></td>
<td>The human-readable name of the plugin module. i.e. the human-readable name of the filter.</td>
<td>The plugin key</td>
</tr>
<tr>
<td>system</td>
<td></td>
<td>Indicates whether this plugin module is a system plugin module (value='true') or not (value='false'). Only available for non-OSGi plugins.</td>
<td>false</td>
</tr>
</tbody>
</table>
weight
The weight of the filter, used to decide which order to place the filter in the chain for filters which have specified the same 'location' attribute (see above). The higher weight, the lower the filter's position.

Elements

<table>
<thead>
<tr>
<th>Name</th>
<th>Required</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>description</td>
<td></td>
<td>The description of the plugin module. The 'key' attribute can be specified to declare a localisation key for the value instead of text in the element body. I.e. the description of the filter.</td>
<td></td>
</tr>
<tr>
<td>init-param</td>
<td></td>
<td>Initialisation parameters for the filter, specified using param-name and param-value sub-elements, just as in web.xml. This element and its child elements may be repeated.</td>
<td>N/A</td>
</tr>
<tr>
<td>resource</td>
<td></td>
<td>A resource for this plugin module. This element may be repeated. A 'resource' is a non-Java file that a plugin may need in order to operate. Refer to Adding Plugin and Module Resources for details on defining a resource.</td>
<td>N/A</td>
</tr>
</tbody>
</table>
| url-pattern|          | The pattern of the URL to match. This element may be repeated. The URL pattern format is used in Atlassian plugin types to map them to URLs. On the whole, the pattern rules are consistent with those defined in the Servlet 2.3 API. The following wildcards are supported:  
  *  matches zero or many characters, including directory slashes  
  ?  matches zero or one character  
  Examples  
  /mydir/* matches /mydir/myfile.xml  
  */admin/*/??ml matches /mydir/otherdir/admin/myfile.html | N/A     |

Example

Here is an example atlassian-plugin.xml file containing a single servlet filter:

```xml
<atlassian-plugin name="Hello World Filter" key="example.plugin.helloworld" plugins-version="2">
  <plugin-info>
    <description>A basic Servlet filter module test - says "Hello World!"</description>
    <vendor name="Atlassian Software Systems" url="http://www.atlassian.com"/>
    <version>1.0</version>
  </plugin-info>
  <servlet-filter name="Hello World Servlet" key="helloWorld" class="com.example.myplugins.helloworld.HelloWorldFilter" location="before-dispatch" weight="200">
    <description>Says Hello World, Australia or your name.</description>
    <url-pattern>helloworld</url-pattern>
    <init-param>
      <param-name>defaultName</param-name>
      <param-value>Australia</param-value>
    </init-param>
  </servlet-filter>
</atlassian-plugin>
```

Accessing your Servlet Filter

Your servlet will be accessible within the Atlassian web application via each url-pattern you specify, but unlike the Servlet Plugin Module, the url-pattern is relative to the root of the web application.

For example, if you specify a url-pattern of /helloworld as above, and your Atlassian application was deployed at http://yourserver/jira — then your servlet filter would be accessed at http://yourserver/jira/helloworld.

Notes

Some information to be aware of when developing or configuring a Servlet Filter plugin module:

- Your servlet filter's init() method will not be called on web application startup, as for a normal filter. Instead, this method will be called the first time your filter is accessed after each time it is enabled. This means that if you disable a plugin containing a filter or a single servlet filter module, and re-enable it again, the filter will be re-created and its init() method will be called again.
- Because servlet filters are deployed beneath root, be careful when choosing each url-pattern under which your filter is deployed. If you plan to handle the request in the filter, it is recommended to use a value that will always be unique to the world!

Purpose of this Module Type

Servlet plugin modules enable you to deploy Java servlets as a part of your plugins.

Configuration

The root element for the Servlet plugin module is `<servlet>`. It allows the following attributes and child elements for configuration:

Attributes

<table>
<thead>
<tr>
<th>Name</th>
<th>Required</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>class</td>
<td></td>
<td>The servlet Java class. Must be a subclass of <code>javax.servlet.http.HttpServlet</code>.</td>
<td></td>
</tr>
<tr>
<td>disabled</td>
<td></td>
<td>Indicate whether the plugin module should be disabled by default (value='true') or enabled by default (value='false').</td>
<td>false</td>
</tr>
<tr>
<td>i18n-name-key</td>
<td></td>
<td>The localisation key for the human-readable name of the plugin module.</td>
<td></td>
</tr>
<tr>
<td>key</td>
<td></td>
<td>The identifier of the plugin module. This key must be unique within the plugin where it is defined.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td><img src="https://example.com/tip" alt="Tip" /> Sometimes you will need to uniquely identify a module. Do this with the module complete key. A module with key <code>fred</code> in a plugin with key <code>com.example.modules</code> will have a complete key of <code>com.example.modules:fred</code>. i.e. the identifier of the servlet.</td>
<td></td>
</tr>
<tr>
<td>name</td>
<td></td>
<td>The human-readable name of the plugin module. i.e. the human-readable name of the servlet.</td>
<td>The plugin key.</td>
</tr>
<tr>
<td>system</td>
<td></td>
<td>Indicates whether this plugin module is a system plugin module (value='true') or not (value='false'). Only available for non-OSGi plugins.</td>
<td>false</td>
</tr>
</tbody>
</table>

Elements

<table>
<thead>
<tr>
<th>Name</th>
<th>Required</th>
<th>Description</th>
<th>Default</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>description</td>
<td></td>
<td>The description of the plugin module. The 'key' attribute can be specified to declare a localisation key for the value instead of text in the element body. i.e. the description of the servlet.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>init-param</td>
<td></td>
<td>Initialisation parameters for the servlet, specified using <code>param-name</code> and <code>param-value</code> sub-elements, just as in web.xml. This element and its child elements may be repeated.</td>
<td>N/A</td>
<td></td>
</tr>
<tr>
<td>resource</td>
<td></td>
<td>A resource for this plugin module. This element may be repeated. A 'resource' is a non-Java file that a plugin may need in order to operate. Refer to Adding Plugin and Module Resources for details on defining a resource.</td>
<td>N/A</td>
<td></td>
</tr>
<tr>
<td>url-pattern</td>
<td></td>
<td>The pattern of the URL to match. This element may be repeated. The URL pattern format is used in Atlassian plugin types to map them to URLs. On the whole, the pattern rules are consistent with those defined in the Servlet 2.3 API. The following wildcards are supported:</td>
<td>N/A</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>* matches zero or many characters, including directory slashes</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>? matches zero or one character</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Examples</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>*/mydir/*</code> matches <code>/mydir/myfile.xml</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>/*/admin/*.*?ml</code> matches <code>/mydir/otherdir/admin/myfile.html</code></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Example

Here is an example `atlassian-plugin.xml` file containing a single servlet:

```xml
<atlassian-plugin name="Hello World Servlet" key="example.plugin.helloworld" plugins-version="2">
  <plugin-info>
    <description>A basic Servlet module test - says "Hello World!"</description>
    <vendor name="Atlassian Software Systems" url="http://www.atlassian.com"/>
    <version>1.0</version>
  </plugin-info>
  <servlet name="Hello World Servlet" key="helloWorld"
    class="com.example.myplugins.helloworld.HelloWorldServlet">
    <description>Says Hello World, Australia or your name.</description>
    <url-pattern>/helloworld</url-pattern>
    <init-param>
      <param-name>defaultName</param-name>
      <param-value>Australia</param-value>
    </init-param>
  </servlet>
</atlassian-plugin>
```

Accessing your Servlet

Your servlet will be accessible within the Atlassian web application via each `url-pattern` you specify, beneath the `/plugins/servlet` parent path.

For example, if you specify a `url-pattern` of `/helloworld` as above, and your Atlassian application was deployed at `http://yourserver/jira` — then your servlet would be accessed at `http://yourserver/jira/plugins/servlet/helloworld`.

Notes

Some information to be aware of when developing or configuring a Servlet plugin module:

- Your servlet's `init()` method will not be called on web application startup, as for a normal servlet. Instead, this method will be called the first time your servlet is accessed after each time it is enabled. This means that if you disable a plugin containing a servlet, or a single servlet module, and re-enable it again, the servlet is re-instantiated and its `init()` method will be called again.
- Because all servlet modules are deployed beneath a common `/plugins/servlet` root, be careful when choosing each `url-pattern` under which your servlet is deployed. It is recommended to use a value that will always be unique to the world!

Spring Component Plugins - Old Style

This is an outdated module type

The Spring Component plugin module described below belongs to the first version of the Atlassian Plugin Framework. A new Component plugin module is available to OSGi-based plugins using version 2.x of the Atlassian Plugin Framework, supported in Confluence 2.10 and later.

On this page:

- Old-Style Plugin Module Type
- Purpose of this Module Type
- Ordering of Components

Old-Style Plugin Module Type

We recommend that you use the new plugin module type, rather than the old-style Spring Component described below. Confluence still supports the earlier module type, but the new OSGi-based plugin framework fixes a number of bugs and limitations experienced by the old-style plugin modules.

Purpose of this Module Type

A Spring module allows you to use standard Spring XML configuration tags.

A Spring module appears in `atlassian-plugin.xml` like this:
The above is equivalent to the following configuration in `applicationContext.xml`:

```xml
<spring name="Space Cleaner Job" key="spaceCleanerJob" class="org.springframework.scheduling.quartz.JobDetailBean">
  ...
  any standard spring configuration goes here...
</spring>

Ordering of Components

If you declare a Spring component that refers to another Spring component, you must ensure the referred component is declared first. For example:

```xml
<spring name="Bean A" key="beanA" class="org.springframework.transaction.interceptor.TransactionProxyFactoryBean">
  ...
</spring>

<spring name="Bean B" key="beanB" alias="soapServiceDelegator" class="org.springframework.aop.framework.ProxyFactoryBean">
  <property name="target">
    <ref local="beanA"/>
  </property>
  ...
</spring>
```

Notice that `beanB` refers to `beanA` and that `beanA` is declared before `beanB`. If you don't do it in this order, Confluence will complain that `beanA` does not exist.

Theme Plugins

Themes define a look and feel for Confluence. Confluence ships with several themes that you can use, such as the default theme and or the left-nav theme. Theme plugins, on the other hand, allow you to create your totally customized look and feel. A theme can be applied to an entire Confluence site or to individual spaces.

Stylesheet themes

Creating a theme which only relies on stylesheets and images is much simpler than customising HTML, and more likely to work in future versions of Confluence.

- Creating a Stylesheet Theme

Custom HTML themes

Creating a new theme with custom HTML consists of two steps:

1. Creating a theme with decorators and colour schemes, which defines how each page looks.
2. Packaging and installing a Theme Plugin - themes are part of our plugin system.

Installing your theme

To install it within Confluence, please read Installing and Configuring Plugins Manually.

Example themes

There are several other themes that you can use as examples to learn from and extend.

Stylesheet themes:

- Easy Blue Theme

Custom HTML themes:

- Clickr Theme
Creating a Stylesheet Theme

To create a stylesheet theme, you need to first create your custom stylesheet for Confluence. You can do this using many CSS editing tools. See Styling Confluence with CSS for more information.

Once you have a stylesheet (and optionally images) ready, this guide will show you how to package up your stylesheet for use in Confluence as a theme.

Quick demonstration

The quick demonstration is the Easy Blue theme, which you can download here:

- easy-blue-theme-1.1.jar

You can quickly customise this theme by using a ZIP extractor program (like WinZip, 7-Zip, etc.) to extract the files, change them, then zip it back up into a JAR file and install it in Confluence.

⚠️ Since this theme was developed as a quick stylesheet demonstration for Confluence, it only has limited browser support. See Easy Blue Stylesheet for information about which browsers are supported.

The remainder of this document is a walk-through which describes in detail how to create a theme like this from scratch.

Creating the descriptor file

Each theme plugin needs a plugin descriptor file, called `atlassian-plugin.xml`. For themes with a single stylesheet, the file is very simple. Below is an example with one stylesheet.

**Theme `atlassian-plugin.xml` with one stylesheet**

```xml
<atlassian-plugin
    name="Simple Demo Theme" key="com.example.acme.simple">
  <plugin-info>
    <description>A Confluence stylesheet theme.</description>
    <vendor name="Acme Software Pty Ltd" url="http://acme.example.com"/>
    <version>1.0</version>
  </plugin-info>
  <theme
    key="simple-theme" name="Simple Demo Theme"
    class="com.atlassian.confluence.themes.BasicTheme">
    <!-- CSS -->
    <resource
      type="download" name="demo-theme.css" location="demo-theme.css"/>
    <param
      name="includeClassicStyles" value="false"/>
  </theme>
</atlassian-plugin>
```

To create your new theme from scratch:

- Copy the above XML into a new text file
- Customise the key, name and vendor of your theme throughout the file
- In the `<resource>` tag, put the name of your stylesheet in both the `name` and the `location` attributes
- Save the customised XML file as `atlassian-plugin.xml` in a new directory with your stylesheet.

Packaging the theme

The theme files need to be put into a JAR file. A JAR file is essentially a ZIP file with a `.jar` extension, so you can create it with whatever tool you like.

To use the command-line tool, `jar`, which ships with the Java Development Kit, you can run the following command in the directory with your files:

```
jar cf my-awesome-theme-1.0.jar *.xml *.css *.gif *.png
```

This will wrap up the `atlassian-plugin.xml` file with whatever images and CSS files you have in your directory. Now you can upload the plugin into Confluence.
Now you're done! If your theme is working great now, then you're finished. There might be a few more things you need to know, however. The later sections cover these details about further customisation of your stylesheet theme.

Including the default stylesheet

Most themes that you write for Confluence will actually rely on the default theme stylesheets in Confluence. This includes the standard Confluence fonts, colours, and many other things. To include the Confluence styles in your theme, the `<theme>` tag in your plugin needs to include Confluence's default stylesheet as a resource:

```
<theme>
  <resource type="download" name="default-theme.css" location="/includes/css/default-theme.css"/>
  <param name="includeClassicStyles" value="false"/>
</theme>
```

Including images

For many themes, you will want to pull in custom background images, icons, and so on. This is very easy to do:

- Put the images in the same directory as your CSS and `atlassian-plugin.xml` files.
- Add a resource to your theme descriptor XML file for the image:

```
<resource type="download" name="image-theme.css" location="image-theme.css"/>
<param name="includeClassicStyles" value="false"/>
```

Sample theme

Here's a listing of the files in the source of the Easy Blue theme (demonstrated above):

- `atlassian-plugin.xml`
- `divider.png`
- `easy-blue-theme.css`
- `gradient-comment-side-light.png`
- `gradient-comment-side.png`
- `gradient-comments-light.png`
- `gradient-comments.png`
- `gradient-dark-invert.png`
- `gradient-dark.png`
- `gradient-light.png`
- `home-16.png`
- `theme-icon.gif`

These are all zipped up into the `easy-blue-theme-1.1.jar` file which can be installed into Confluence. In fact, the JAR file is almost exactly the same as the ZIP file. The only difference is a manifest file generated automatically by the `jar` command line tool, which is completely unnecessary for your theme to work in Confluence.

Here's the plugin descriptor file:
Creating a Theme Plugin

- Using Decorators
- Using Stylesheets
- Using Colour Schemes

Using Decorators

A decorator defines Confluence page layout. By modifying a decorator file, you can move 'Attachments' tab from the left of the screen to the right or remove it completely. Decorator files are written in the Velocity templating language and have the VMD extension. You can familiarise yourself with Velocity at the Velocity Template Overview and decorators in general at the Sitemesh homepage.

Decorators, Contexts and Modes

Confluence comes bundled with a set of decorator files that you can customize. Instead of having one decorator file for each screen, we’ve grouped together similar screens (example: view and edit page screens) to simplify editing layouts.

There is some terminology that we use when talking about decorators that should be defined. We’ve grouped all the screens in Confluence into major categories which we call contexts. Within each context are various modes (ways of viewing that particular layout).

The following table summarises how decorators use contexts and modes:

<table>
<thead>
<tr>
<th>Decorator</th>
<th>Context</th>
<th>Mode</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>page.vmd</td>
<td>page</td>
<td>'view', 'edit', 'edit-preview', 'view-information', and 'view-attachments'</td>
<td></td>
</tr>
<tr>
<td>blogpost.vmd</td>
<td>blogpost (news)</td>
<td>'view', 'edit', 'edit-preview', and 'remove'</td>
<td>We prefer to use 'news' as an end-user term; all templates and classes use 'blogpost' to indicate RSS related content</td>
</tr>
<tr>
<td>mail.vmd</td>
<td>mail</td>
<td>'view', 'view-thread' and 'remove'</td>
<td></td>
</tr>
<tr>
<td>global.vmd</td>
<td>global</td>
<td>'dashboard', 'view-profile', 'edit-profile', 'change-password-profile', 'edit-notifications-profile'</td>
<td></td>
</tr>
<tr>
<td>main.vmd</td>
<td>n/a (header and footer formatting)</td>
<td></td>
<td>main.vmd is used to control the header and footer of each page, not the page specific presentation logic</td>
</tr>
</tbody>
</table>
space.vmd | space-pages | list-alphabetically,  
| list-recently-updated,  
| list-content-tree, create-page  
| space.vmd handles a wide range of options, this context is  
| accessed by clicking on 'browse space' in the default theme  
| of Confluence (tabbed theme)  

| space-mails | view-mail-archive  
| space-blogposts | view-blogposts, create-blogpost  
| space-templates | view-templates  
| space-operations | view-space-operations  

| space-administration | view-space-administration, list-permission-pages  

Example

As an example on how to use the table above, say we found the 'Attachments' tab on the view page screen annoying and wanted to remove it. We could make this layout change in the page.vmd file - where the 'view' mode is handled (as shown below).

```velocity
#parse
or . These include files pass important information about the space to other space decorators and hence must be included.
```

The Theme Helper Object

When editing decorator files you will come across a variable called $helper - this is the theme helper object.

The following table summarises what this object can do:

<table>
<thead>
<tr>
<th>Behaviour</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>$helper.domainName</td>
<td>displays the base URL of your Confluence instance on your page. This is useful for constructing links to your own Confluence pages.</td>
</tr>
<tr>
<td>$helper.spaceKey()</td>
<td>returns the current space key or null if in a global context.</td>
</tr>
<tr>
<td>$helper.spaceName</td>
<td>returns the name of the current space</td>
</tr>
<tr>
<td>$helper.renderConfluenceMacro(&quot;{create-space-button}&quot;)</td>
<td>renders a call to a [Confluence Macro] for the velocity context</td>
</tr>
<tr>
<td>$helper.getText(&quot;key.key1&quot;)</td>
<td>looks up a key in a properties file matching key.key1=A piece of text and returns the matching value (&quot;A piece of text&quot;)</td>
</tr>
<tr>
<td>$helper.action</td>
<td>returns the XWork action which processed the request for the current page.</td>
</tr>
</tbody>
</table>

If you are on a page or space screen you also have access to the actual page and space object by using $helper.page and $helper.space respectively.

If you want to delve more into what other methods are available in this object, please see our API's for ThemeHelper.

Velocity macros

Finally, the last thing you need to decipher decorator files is an understanding of macros. A velocity macro looks like this:

```velocity
#myVelocityMacro()
```

In essence, each macro embodies a block of code. We've used these macros to simplify decorator files and make them easier to modify.

For example, the #editPageLink() macro will render the edit page link you see on the 'View Page Screen'. All the logic which checks whether a certain user has permissions to edit pages and hence see the link are hidden in this macro. As the theme writer, you need only care about calling it.
The easiest way to acquaint yourself with the macros is to browse through your macros.vm file, located in /template/includes/macros.vm (under the base Confluence installation).

Writing your own Velocity Macros

Velocity macros are very useful for abstracting out common presentation logic into a function call and for keeping decorators clean. If you wish to use them for your theme you can either:

Write your own Macros file

Write your own Velocity macros library file, as we've done with macros.vm. If you elect to do this you must locate the velocity.properties file beneath WEB-INF/classes and tell the Velocity engine where your library file can be located, relative to the base installation of Confluence.

Use Inline Velocity Macros.

Inline velocity macros, when loaded once, can be called from anywhere. See decorators/mail.vmd for examples of inline decorators.

Using Stylesheets

Stylesheets can be defined for a theme and they will automatically be included by Confluence when pages are displayed with your theme. You simply need to add a resource of type download to your theme module. Please note that the resource name must end with .css for it to be automatically included by Confluence.

Now, in the HTML header of any page using your theme, a link tag to your theme stylesheets will be created by Confluence. If you have a look at the source of combined.css, it will contain imports to all your theme stylesheets.

Theme stylesheets are included after all the default Confluence styles and colour schemes. This is to ensure that your theme styles can override and take precedence over the base styles provided by Confluence.

Using Colour Schemes

Users can customise their own colour scheme (regardless of the theme selected) for a particular space under Space Administration.
The following colours can be customised for this colour scheme.

<table>
<thead>
<tr>
<th>Component</th>
<th>Colour</th>
</tr>
</thead>
<tbody>
<tr>
<td>Top Bar</td>
<td>#003366</td>
</tr>
<tr>
<td>Tab Navigation Background</td>
<td>#3c78b5</td>
</tr>
<tr>
<td>Tab Navigation Text</td>
<td>#ffffff</td>
</tr>
<tr>
<td>Breadcrumbs Text</td>
<td>#ffffff</td>
</tr>
<tr>
<td>Space Name Text</td>
<td>#999999</td>
</tr>
<tr>
<td>Heading Text</td>
<td>#003366</td>
</tr>
<tr>
<td>Links</td>
<td>#003366</td>
</tr>
<tr>
<td>Borders and Dividers</td>
<td>#3c78b5</td>
</tr>
<tr>
<td>Tab Navigation Background Highlight</td>
<td>#003366</td>
</tr>
<tr>
<td>Tab Navigation Text Highlight</td>
<td>#ffffff</td>
</tr>
<tr>
<td>Top Bar Menu Selected Background</td>
<td>#335699</td>
</tr>
<tr>
<td>Top Bar Menu Item Text</td>
<td>#003366</td>
</tr>
<tr>
<td>Page Menu Selected Background</td>
<td>#6999cc</td>
</tr>
<tr>
<td>Page Menu Item Text</td>
<td>#5b5353</td>
</tr>
<tr>
<td>Menu Item Selected Background</td>
<td>#6999cc</td>
</tr>
<tr>
<td>Menu Item Selected Text</td>
<td>#ffffff</td>
</tr>
</tbody>
</table>

You may choose to respect these user configured colour schemes in your theme or ignore them completely by overriding them in your theme stylesheets. If you would like to respect the configured colour schemes for your new UI elements, you should specify a velocity stylesheet resource in your theme module.

Please note that the `resource` name must end with `.vm`, and the `type` must be `stylesheet` for it to be automatically rendered as a velocity template by Confluence. This velocity stylesheet will essentially contain css for colours with references to the `color scheme bean` (which is available to you via the action). For example:

```xml
<theme key="mytheme" .... >
  ...
  <resource type="stylesheet" name="my-theme-colors.vm" location="templates/clickr/my-theme-colors.vm"/>
  ...
</theme>
```

As the velocity stylesheet is rendered as a velocity template, you will need to escape any #ids (e.g. breadcrumbs) that match velocity macro names.

Additionally, you may choose to provide your theme with a pre-defined colour scheme (which users will be able to select under Space Administration). This pre-defined colour scheme will take precedence if no custom user one is defined for the space. To define a theme's colour scheme, you need to add a colour scheme module and link to it in the theme module. For example:

```xml

#breadcrumbs a {
  color: $action.colorScheme.linkColor;
}
#myNewElement {
  color: $action.colorScheme.headingTextColor;
}
.myNewElementClass {
  border-color: $action.colorScheme.borderColor;
}
...```

As the velocity stylesheet is rendered as a velocity template, you will need to escape any #ids (e.g. breadcrumbs) that match velocity macro names.
The class of a colour scheme must implement `com.atlassian.confluence.themes.ColourScheme`. The `com.atlassian.confluence.themes.BaseColourScheme` class provided with Confluence sets the colours based on the module's configuration.

The available colours correspond to those that you would configure under Space Administration > Colour Scheme:

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>property.style.topbarcolour</td>
<td>The strip across the top of the page</td>
<td>#003366</td>
</tr>
<tr>
<td>property.style.breadcrumbstextcolour</td>
<td>The breadcrumbs text in the top bar of the page</td>
<td>#ffffff</td>
</tr>
<tr>
<td>property.style.spacenamecolour</td>
<td>The text of the current space name, or Confluence in the top left</td>
<td>#999999</td>
</tr>
<tr>
<td>property.style.headingtextcolour</td>
<td>All heading tags throughout the site</td>
<td>#003366</td>
</tr>
<tr>
<td>property.style.linkcolour</td>
<td>All links throughout the site</td>
<td>#003366</td>
</tr>
<tr>
<td>property.style.bordercolour</td>
<td>Table borders and dividing lines</td>
<td>#3c78b5</td>
</tr>
<tr>
<td>property.style.navbgcolour</td>
<td>Background of tab navigation buttons</td>
<td>#3c78b5</td>
</tr>
<tr>
<td>property.style.navtextcolour</td>
<td>Text of tab navigational buttons</td>
<td>#ffffff</td>
</tr>
<tr>
<td>property.style.navselectedbgcolour</td>
<td>Background of tab navigation buttons when selected or hovered</td>
<td>#003366</td>
</tr>
<tr>
<td>property.style.navselectedtextcolour</td>
<td>Text of tab navigation buttons when selected or hovered</td>
<td>#ffffff</td>
</tr>
<tr>
<td>property.style.topbarmenuselectedbgcolour</td>
<td>Background of top bar menu when selected or hovered</td>
<td>#336699</td>
</tr>
<tr>
<td>property.style.topbarmenuitemtextcolour</td>
<td>Text of menu items in the top bar menu</td>
<td>#003366</td>
</tr>
<tr>
<td>property.style.menuselectedbgcolour</td>
<td>Background of page menu when selected or hovered</td>
<td>#6699cc</td>
</tr>
<tr>
<td>property.style.menutextcolour</td>
<td>Text of menu items in the page menu</td>
<td>#535353</td>
</tr>
<tr>
<td>property.style.menutemselectedbgcolour</td>
<td>Background of menu items when selected or hovered</td>
<td>#6699cc</td>
</tr>
<tr>
<td>property.style.menutemselectedtextcolour</td>
<td>Text of menu items when selected or hovered</td>
<td>#ffffff</td>
</tr>
</tbody>
</table>

**Packaging and installing a Theme Plugin**

**The Theme Plugin Module**

The theme module defines the theme itself. When someone in Confluence selects a theme either globally or within a space, they are selecting from the available theme modules.
module definition into a theme.

A theme can contain an optional `colour-scheme` element that defines which colour-scheme module this theme will use, and any number of `layout` elements that define which layouts should be applied in this theme. Refer to these modules by their `module complete key`.

It is possible for a theme to use modules that aren’t in the same plugin as the theme. Just keep in mind that your theme will be messed up if some plugin that the theme depends on is removed.

### Installing the Theme

Themes are installed as ‘plugin modules’. The plugin module is a collection of files, usually zipped up in a jar archive, which tells Confluence how to find the decorators and colour-scheme of your theme.

Plugins are a general topic in Confluence and have other uses than themes. In every case, the central configuration file, which describes the plugin to Confluence, is named `atlassian-plugin.xml`.

There are two steps to creating the plugin module.

1. Create the central configuration file for the theme: `atlassian-plugin.xml`
2. Create the jar archive for your theme: bundling your theme

Writing the `atlassian-plugin.xml` file for your theme.

The structure of an `atlassian-plugin.xml` file is fairly self-explanatory. In the code segment below you will find a full example of an `atlassian-plugin.xml`, which lists

- each of the decorators you have defined to customize Confluence
- your colour scheme

in a way which Confluence can use to override the default theme. In other words, this XML tells Confluence to look in certain locations for replacement decorators when processing a request.
The class which each decorator, or layout, is mapped to must implement com.atlassian.confluence.themes.VelocityDecorator.

The layout entry must provide an `overrides` attribute which defines which decorator within Confluence is being overridden by the theme.
Importantly, when telling Confluence to override a particular decorator with another one, the location of the custom decorator is specified; for example:

```xml
<layout key="page" name="Page Decorator" class="com.atlassian.confluence.themes.VelocityDecorator"
        overrides="/decorators/page.vmd">
    <resource type="velocity" name="decorator"
              location="com/atlassian/confluence/themes/tabless/page.vmd"/>
</layout>
```

The location attribute needs to be represented in the jar archive you will use to bundle your theme.

**Bundling the Theme**

Your decorators should be placed in a directory hierarchy which makes sense to you. The atlassian-plugin.xml file should be placed at the top level of the directory structure, afterwards the decorators should be placed in directories which make a meaningful division of what they do. It is your choice as to how the structure is laid out, each decorator could even be placed alongside atlassian-plugin.xml. The essential thing is for the location attribute of each decorator to accurately tell Confluence how to load it.

Thus, a recursive directory listing of the example theme above gives:

<table>
<thead>
<tr>
<th>File Path</th>
</tr>
</thead>
<tbody>
<tr>
<td>atlassian-plugin.xml</td>
</tr>
<tr>
<td>com/atlassian/confluence/themes/tabless/global.vmd</td>
</tr>
<tr>
<td>com/atlassian/confluence/themes/tabless/space.vmd</td>
</tr>
<tr>
<td>com/atlassian/confluence/themes/tabless/mail.vmd</td>
</tr>
<tr>
<td>com/atlassian/confluence/themes/tabless/blogpost.vmd</td>
</tr>
<tr>
<td>com/atlassian/confluence/themes/tabless/main.vmd</td>
</tr>
<tr>
<td>com/atlassian/confluence/themes/tabless/page.vmd</td>
</tr>
</tbody>
</table>

**Theme Configuration**

The themes can be configured via the Configuration link on the Choose Theme page on both the space and global level.

**Choose a Theme**

Assign a look and feel from an installed theme plugin. This theme will override any manually layouts.

- **Plain Website Theme** — demonstrates a plain web page view.
- **Tabless Theme** — plain Confluence theme.
- **Left Navigation Theme** — Left Navigation Bar Theme.

For example, the Left Navigation Theme allows for the specification of the title of the page which page should be used for navigation. The XWork module allows for developing complex configurations for themes, which can be saved in a config file.

**Setting up the atlassian-plugin.xml**

Configuration path parameter.

Specify the path to the configuration action in the atlassian-plugin.xml:

```xml
<theme key="dinosaurs" name="Dinosaur Theme"
       class="com.atlassian.confluence.themes.BasicTheme">
    <description>A nice theme for the kids</description>
    <layout key="com.example.themes.dinosaur:main"/>
    <layout key="com.example.themes.corporate:mail-template"/>
    <param name="space-config-path" value="/themes/dinosaurs/configuretheme.action"/>
    <param name="global-config-path" value="/admin/themes/dinosaurs/configuretheme.action"/>
</theme>
```

Note that two new parameters have been specified in the above xml.

- **space-config-path** points to the action connected with the space theme configuration.
- **global-config-path** points to the action connected with the global theme configuration.

As themes can be specified either on a global or space level, different configuration actions can be implemented for each level. If there is no need for configuration on a level, simply don’t specify the config path.

**XWork Actions**

Specify the configuration actions via the Xwork plugin module.
Define two packages, one for the space-level and one for the global configuration.

```xml
<xwork name="themeaction" key="themeaction">
  <package name="dinosaurs" extends="default" namespace="/themes/dinosaurs">
    <default-interceptor-ref name="defaultStack" />
    <action name="configuretheme" class="com.atlassian.confluence.extra.dinosaurs.ConfigureThemeAction" method="doDefault">
      <result name="input" type="velocity">/templates/dinosaurs/configuretheme.vm</result>
    </action>
    <action name="doconfiguretheme" class="com.atlassian.confluence.extra.dinosaurs.ConfigureThemeAction">
      <result name="success" type="redirect">/spaces/choosetheme.action?key=${key}</result>
    </action>
  </package>
  <package name="dinosaurs-admin" extends="default" namespace="/admin/themes/dinosaurs">
    <default-interceptor-ref name="defaultStack" />
    <action name="configuretheme" class="com.atlassian.confluence.extra.dinosaurs.ConfigureThemeAction" method="doDefault">
      <result name="input" type="velocity">/templates/dinosaurs/configurethemeadmin.vm</result>
    </action>
    <action name="doconfiguretheme" class="com.atlassian.confluence.extra.dinosaurs.ConfigureThemeAction">
      <result name="success" type="redirect">/admin/choosetheme.action</result>
    </action>
  </package>
</xwork>
```

- `configuretheme` defines the velocity file used to display the input view.
- `doconfiguretheme` defines the action to redirect to after the configuration was successful.

Note that the config-path parameters specified above matches the namespace plus the name of the action.

For example, given the above atlassian-plugin.xml, the configuretheme action would be accessed at

```
http://yours server/confluence/themes/dinosaurs/configuretheme.action
```

The namespace of the global action has to start with `/admin`. Otherwise the action will not be decorated by the admin decorator, and the navigation of the admin area will not be visible.

---

**Saving Theme Configurations with Bandana**

To persist the configuration of a theme you can make use of the Bandana persistence framework.

For example, the Left Navigation Theme uses the persister to store its configuration values.

**Defining a Settings Bean**

The recommended way of saving the settings, is to create a simple configuration bean which implements the Serializable interface. The bean for the Left Navigation Theme for example, simply consists of two String variables and their getter and setter methods.
Saving the Bean

Bandana can be used to save a configuration object with a given context, where the context refers to a space. The setValue function of the BandanaManager has three arguments:

- @param context The context to store this value in
- @param key The key of the object
- @param value The value to be stored

```java
package com.atlassian.confluence.extra.leftnavigation;
import java.io.Serializable;
public class LeftNavSettings implements Serializable {
    private String space;
    private String page;

    public String getSpace() {
        return space;
    }

    public void setSpace(String space) {
        this.space = space;
    }

    public String getPage() {
        return page;
    }

    public void setPage(String page) {
        this.page = page;
    }
}
```

A Context can be defined on two levels:

- Global: new ConfluenceBandanaContext()
- Space level: new ConfluenceBandanaContext(spaceKey)

Retrieving the Bean

The configuration object can be retrieved by using bandanaManager.getValue. This method will get the configuration object, starting with the given context and looking up in the context hierarchy if no context is found.

```java
// Create a setting bean.
LeftNavSettings settings = new LeftNavSettings();
settings.setSpace("example Space");
settings.setPage("example Page");

// Save the bean with the BandanaManager
bandanaManager.setValue(new ConfluenceBandanaContext(spaceKey), THEMEKEY, settings);
```

Updating a theme for editable comments

This is a simple how-to that shows the steps to upgrade your plugin for editable comments.

Modify `sharedcomments.vmd`

Making your themes compatible with editable comment only requires modifying `sharedcomments.vmd`. There are 3 parts to update. A good example of this is the Clickr Theme.

Adding the edit link
First to enable editable comment you will need to give access to the edit function. Adding the link is as simple as adding the following piece of code near your existing ‘Permalink’ and ‘Remove Comment’ links:

```groovy
#if { $permissionHelper.canEdit($remoteUser, $comment ) }
| a id="edit-$comment.id" href="$req.contextPath$generalUtil.customGetPageUrl($page)showComments=true&amp;editComment=true&amp;focusedCommentId=$comment.id" action='getText('edit.name')'&gt;</a
#end
```

Enable inline editing

Editing a comment happens inline. Therefore the editor must be added when rendering the comment being edited as follow:

```groovy
#if { $focusedCommentId == $comment.id && $action.editComment && $permissionHelper.canEdit($remoteUser, $comment ) }
<!--bodytag (Component "name='content'" "theme='notable'" "template='wiki-textarea.vm'"
#param ("formname" "editcommentform")
#param ("spaceKey" "$generalUtil.urlEncode($spaceKey)")
#param ("rows" 15)
#param ("cols" 70)
#param ("width" "100%")
#param ("tabindex" "4")
#param ("editable" "false")
#param ("initialFocus" "false")
#param ("edit" "true")
#param ("heartbeat" "false")
#param ("wikiContent" "$comment.content")
#param ("wysiwygContent" "$action.helper.wikiStyleRenderer.convertWikiToXHtml($comment.toPageContext(), $comment.content)
#end
#
#commentSubmission()
</form>

#end
```

Add update information

This step is optional but it always nice for user to know when a comment has been updated and by who. The following piece of code gets the necessary information.

```groovy
#if { $action.helper.shouldRenderCommentAsUpdated($comment) }
<br/>
#if { $comment.creatorName == $comment.lastModifierName }
$action.getText("comment.updated.by.author", ["#usernameLink ($comment.lastModifierName)
$action.dateFormatter.formatDateTime( $comment.lastModificationDate )
#end
#end
```

The `shouldRenderCommentAsUpdated` method is a convenience method that checks whether the comment has been updated by its creator more than 10 minutes after being created. It exists so that comments will not get cluttered with useless information because of a quick fix made shortly after the comment is posted. One can adjust the time frame by passing a number of seconds as the second argument to this method.

Finally, if the updater of the comment is different to the original author of the comment, his name is displayed.

**Trigger Plugins**

> Trigger plugin modules are available in Confluence 2.2 and later.

Trigger plugin modules enable you to schedule when your Job Plugins are scheduled to run Confluence.

- For more information about plugins in general, read Confluence Plugin Guide.
- To learn how to install and configure plugins (including macros), read Installing and Configuring Plugins Manually.
- For an introduction to writing your own plugins, read Writing Confluence Plugins

**Trigger Plugin Module**

1091
The Trigger plugin module schedules Jobs within a plugin. Triggers are one of two types:

- cron - jobs are scheduled using cron syntax
- simple - jobs are scheduled to repeat every X seconds

Here is an example `atlassian-plugin.xml` fragment containing a Job with its corresponding Trigger module using a cron-style expression (for reference, this expression will execute the job with key 'myJob' every minute):

```xml
<atlassian-plugin name="Sample Component" key="confluence.extra.component">
  ...
  <job key="myJob" name="My Job">
    class="com.example.myplugin.jobs.MyJob" />
  <trigger key="myTrigger" name="My Trigger">
    <job key="myJob" />
    <schedule cron-expression="0 * * * * ?" />
  </trigger>
  ...
</atlassian-plugin>
```

For the `<trigger>` element:

- the `name` attribute represents how this component will be referred to in the Confluence interface.
- the `key` attribute represents the internal, system name for your Trigger.
- the `class` attribute represents the class of the Job to be created. The class must have a no-argument constructor, or it will not be able to be instantiated by Confluence.

For more details on the cron expressions, see the Quartz documentation for `CronTrigger`.

Here is another example, this time using a simple trigger that repeats every 3600000 milliseconds (1 hour) and will only repeat 5 times:

```xml
...
<trigger key="myTrigger" name="My Trigger">
  <job key="myJob" />
  <schedule repeat-interval="3600000" repeat-count="5" />
</trigger>
...
```

**User Macro Plugins**

✅ You can create user macros without writing a plugin through the User Macros administration menu.

**Adding a user macro plugin**

User Macros are a kind of Confluence plugin module.

- For more information about plugins in general, read Confluence Plugin Guide.
- To learn how to install and configure plugins (including macros), read Installing and Configuring Plugins Manually.
- For an introduction to writing your own plugins, read Writing Confluence Plugins

⚠️ User macro plugin modules are available in Confluence 2.3 or later

**User Macro Plugin Modules**

User macro plugin modules allow plugin developers to define simple macros directly in the `atlassian-plugin.xml` file, without writing any additional Java code. User macro plugin modules are functionally identical to User Macros configured through the administrative console, except that they can be packaged and distributed in the same way as normal plugins.

ℹ️ User macros installed by plugin modules do not appear in the user macro section of the administrative console, and are not editable from within the user interface. They appear just as normal plugin modules in the plugin interface.

**Configuring a Macro Plugin Module**

Macro plugin modules are configured entirely inside the `atlassian-plugin.xml` file, as follows:
The `<template>` section is required, and defines the velocity template that will be used to render the macro.

All the velocity variables available in User Macros are available in user macro plugin modules.

The name and key of the macro must be specified the same as Macro Plugins.

No class attribute is required.

The attributes of the `<user-macro>` element match the corresponding configuration for user macros:

### Available Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Required</th>
<th>Default Value</th>
<th>Allowed Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>hasBody</td>
<td>No</td>
<td>false</td>
<td>• true – the macro expects a body (i.e. (hello)World(hello))&lt;br&gt;• false – the macro does not expect a body (i.e. Hello, (name))</td>
</tr>
<tr>
<td>bodyType</td>
<td>No</td>
<td>raw</td>
<td>• raw – the body will not be processed before being given to the template&lt;br&gt;• escapehtml – HTML tags will be escaped before being given to the template&lt;br&gt;• rendered – the body will be rendered as wiki text before being given to the template</td>
</tr>
<tr>
<td>outputType</td>
<td>No</td>
<td>html</td>
<td>• html – the template produces HTML that should be inserted directly into the page&lt;br&gt;• wiki – the template produces Wiki text that should be rendered to HTML before being inserted into the page</td>
</tr>
</tbody>
</table>

### Velocity Context Plugins

Velocity Context plugin modules are available in Confluence 1.4 and later.

Velocity Context plugin modules enable you to add components to Confluence’s velocity context, making those components available in templates rendered from decorators, themes, XWork actions or macros.

- For more information about plugins in general, read Confluence Plugin Guide.
- To learn how to install and configure plugins (including macros), read Installing and Configuring Plugins Manually.
- For an introduction to writing your own plugins, read Writing Confluence Plugins.

### Velocity Context Plugin Module

Each component module adds a single object to Confluence’s default velocity context. This context is the collection of objects that are passed to each velocity template during rendering of macros, decorators, themes and XWork actions. This allows you to create helper objects that perform tasks too complex to represent in Velocity templates.

The objects are autowired by Spring before being added to the context.

Here is an example `atlassian-plugin.xml` file containing a single velocity context module:

```xml
<atlassian-plugin name='Sample Component' key='confluence.extra.component'>
  ...
  <velocity-context-item key='myVelocityHelper' name='My Plugin’s Velocity Helper' context-key='myVelocityHelper'
    class='com.example.myplugin.helpers.MyVelocityHelper' />
  ...
</atlassian-plugin>
```

- the `name` attribute represents how this component will be referred to in the Confluence interface.
The key attribute represents the internal, system name for your component.

- The context-key attribute represents the variable that will be created in Velocity for this item. So if you set a context-key of myVelocityHelper, the object will be available as \$myVelocityHelper in Velocity templates.
- The class attribute represents the class of the component to be created. The class must have a no-argument constructor, or it will not be able to be instantiated by Confluence.

### Web Resource Plugins

Please take a look at our overview of how and why you should include Javascript and CSS resources into your plugin. The page below gives specific details of the Web Resource plugin module type.

**Including your web resource in a specific context**

In Confluence 2.10 we added the ability to specify web resources like CSS and JavaScript to be included in specific contexts of Confluence. Please see below for the currently available contexts and more information.

**On this page:**

- Purpose of this Module Type
- Configuration
  - Attributes
  - Elements
- Example
  - Referring to Web Resources
    - Batched Mode
    - Non-Batched Mode
- Notes
- Web Resource Contexts

### Purpose of this Module Type

Web Resource plugin modules allow plugins to define downloadable resources. If your plugin requires the application to serve additional static Javascript or CSS files, you will need to use downloadable web resources to make them available. Web resources are added at the top of the page in the header with the cache-related headers set to never expire.

### Configuration

The root element for the Web Resource plugin module is `web-resource`. It allows the following attributes and child elements for configuration:

#### Attributes

<table>
<thead>
<tr>
<th>Name</th>
<th>Required</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>class</td>
<td></td>
<td>The class which implements this plugin module. The class you need to provide depends on the module type. For example, Confluence theme, layout and colour-scheme modules can use classes already provided in Confluence. So you can write a theme-plugin without any Java code. But for macro and listener modules you need to write your own implementing class and include it in your plugin.</td>
<td></td>
</tr>
<tr>
<td>disabled</td>
<td></td>
<td>Indicate whether the plugin module should be disabled by default (value='true') or enabled by default (value='false').</td>
<td>false</td>
</tr>
<tr>
<td>i18n-name-key</td>
<td></td>
<td>The localisation key for the human-readable name of the plugin module.</td>
<td></td>
</tr>
<tr>
<td>key</td>
<td>✓</td>
<td>The identifier of the plugin module. This key must be unique within the plugin where it is defined. A module with key fred in a plugin with key com.example.modules will have a complete key of com.example.modules:fred. i.e. the identifier of the web resource.</td>
<td>N/A</td>
</tr>
<tr>
<td>name</td>
<td></td>
<td>The human-readable name of the plugin module. i.e. the human-readable name of the web resource.</td>
<td></td>
</tr>
<tr>
<td>system</td>
<td></td>
<td>Indicates whether this plugin module is a system plugin module (value='true') or not (value='false'). Only available for non-O SGi plugins.</td>
<td>false</td>
</tr>
</tbody>
</table>

#### Elements

<table>
<thead>
<tr>
<th>Name</th>
<th>Required</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>description</td>
<td></td>
<td>The description of the plugin module. The 'key' attribute can be specified to declare a localisation key for the value instead of text in the element body. i.e. the description of the resource.</td>
<td></td>
</tr>
</tbody>
</table>
A resource for this plugin module. This element may be repeated. A ‘resource’ is a non-Java file that a plugin may need in order to operate. Refer to Adding Plugin and Module Resources for details on defining a resource. Currently, supported file types are .css and .js. For web resources, the type attribute must be 'download'.

Dependencies for the web resource module. A web resource can depend on other web resource(s) to be available. Dependencies are defined in the format ‘pluginKey:webResourceKey’ e.g. <dependency>confluence.web.resources:ajs</dependency>

Note: This element is only available from 2.2.

Here is an example atlassian-plugin.xml file containing a single web resource:

```xml
<atlassian-plugin name="Hello World Resource" key="example.plugin.helloworld" plugins-version="2">  
  <plugin-info>  
    <description>A basic web resource module test</description>  
    <vendor name="Atlassian Software Systems" url="http://www.atlassian.com"/>  
    <version>1.0</version>  
  </plugin-info>  
  <web-resource key="scriptaculous" name="Scriptaculous">  
    <resource type="download" name="scriptaculous.js" location="includes/js/effects/scriptaculous.js"/>  
    <resource type="download" name="effects.js" location="includes/js/effects/effects.js"/>  
  </web-resource>  
</atlassian-plugin>
```

Referring to Web Resources

In your plugin, you need to refer to a WebResourceManager and call the requireResource() method. The reference to WebResourceManager can be injected into your constructor:

```java
public MyServlet extends HttpServlet {  
  private WebResourceManager webResourceManager;  
  public MyServlet(WebResourceManager webResourceManager) {  
    this.webResourceManager = webResourceManager;  
  }  
  protected final void doGet(HttpServletRequest httpServletRequest, HttpServletResponse httpServletResponse) throws IOException {  
    webResourceManager.requireResource("example.plugin.helloworld:scriptaculous"); // should be the full module key for the <webreference> module.  
    // more code  
  }  
}
```

Batched Mode

The default mode for serving web resources in Plugins 2.2 is batched mode. Batched mode refers to the serving of multiple plugin resources (of the same type) in one request. For example, the two scriptaculous.js and effects.js resources defined above would be served in one request, containing both scriptaculous.js and effects.js. Hence, batching reduces the number of HTTP requests that web browsers need to make to load a web page.

URLs for batched resources are in the following format:

```text
SERVER_ROOT/s/BUILD_NUM/PLUGIN_VERSION/SYSTEM_COUNTER/_/download/batch/js/PLUGIN_KEY:MODULE_KEY/BATCHNAME.js  
SERVER_ROOT/s/BUILD_NUM/PLUGIN_VERSION/SYSTEM_COUNTER/_/download/batch/css/PLUGIN_KEY:MODULE_KEY/BATCHNAME.css
```

For the above scriptaculous example, the following code will be inserted in the header of the page:

```html
<script type="text/javascript" src="http://jira.example.com/s/170/1.0/1/_/download/batch/js/jira.extra.impresence:scriptaculous/jiraextra.impresence:scriptaculous.js"></script>
```
Non-Batched Mode

Prior to Plugins 2.2, each resource defined was served separately. To revert to this non-batched mode, you can either

- use the system property `{{plugin.webresource.batching.off=true}}` to turn off batching system wide
- or define a 'batch' parameter on each resource like so:

```xml
<resource type="download" name="scriptaculous.js" location="includes/js/effects/scriptaculous.js" >
  <param name="batch" value="false"/>
</resource>
```

URLs for non batched resources are in the following format:

```
SERVER_ROOT/s/BUILD_NUM/PLUGIN_VERSION/SYSTEM_COUNTER/_/download/resources/PLUGIN_KEY:MODULE_KEY/RESOURCE_NAME
```

For the above scriptaculous example with batching turned off, the following code will be inserted in the header of the page:

```html
<script type="text/javascript"
src="http://jira.example.com/s/170/1.0/1/_/download/resources/jira.extra.impresence:scriptaculous/scriptaculous.js"></script>
<script type="text/javascript"
src="http://jira.example.com/s/170/1.0/1/_/download/resources/jira.extra.impresence:scriptaculous/effects.js"></script>
```

Notes

- Since the resources are returned with headers that tell the browser to cache the content indefinitely, during development, you may need to hold down the "shift" key while reloading the page to force the browser to re-request the files.

Web Resource Contexts

In Confluence 2.10 and later, you can automatically include web resources like CSS and JavaScript on all screens of a specific type in the application. These are called web resource contexts. The currently available contexts are:

<table>
<thead>
<tr>
<th>Context</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>main</td>
<td>Everywhere except administration screens</td>
</tr>
<tr>
<td>admin</td>
<td>Administration screens. Use with care because poorly formed CSS or JavaScript can prevent access to administer Confluence.</td>
</tr>
<tr>
<td>dashboard</td>
<td>Dashboard</td>
</tr>
<tr>
<td>editor</td>
<td>Anywhere an editor appears (fixed in 3.1 to work in comment editor).</td>
</tr>
<tr>
<td>page</td>
<td>Any page-related screen like view, edit, attachments, info; but not blog post, space or global screens.</td>
</tr>
<tr>
<td>blogpost</td>
<td>Any blog-related screen like view, edit, attachments, info; not page, space or global screens.</td>
</tr>
<tr>
<td>space</td>
<td>Any space-related screen, like those found in the top section of the Browse menu.</td>
</tr>
</tbody>
</table>

Technical note: the 'page', 'blogpost' and 'space' contexts correspond to the usage of the 'page.vmd', 'blogpost.vmd' and 'space.vmd' decorators in Confluence.

To configure your web resource to be included for example in the 'space' and 'page' contexts you add `<context>` child elements to your `<web-resource>` element in your `atlassian-plugin.xml`:

```xml
<web-resource name="Resources" key="resources">
  <resource name="foo.js" type="download" location="resources/foo.js">
    <context>space</context>
    <context>page</context>
  </resource>
</web-resource>
```

Using web resource contexts allows you to provide plugins that dynamically create HTML using JavaScript on any page in Confluence. For example, the Content Navigation Plugin includes a snippet of JavaScript on every page in the application, which listens for a particular keyboard shortcut to open a little search box on top the Confluence UI.
Introducing new contexts

If your plugin adds a lot of screens to Confluence, it might be annoying to put many `#requireResource()` declarations in each Velocity template. An alternative is to introduce a new web resource context for your plugin which your plugin web resources (or any other plugin web resource) can hook into, to be automatically included on these screens.

To introduce a new context in your plugin Velocity templates, you can call the `#requireResourcesForContext()` Velocity macro:

```
#requireResourcesForContext("com.acme.plugin.fancy-context")
```

This will include any resource in the page that specifies a context like this in its definition:

```xml
<context>com.acme.plugin.fancy-context</context>
```

We recommend you namespace your new contexts in this way so as not to clash with any future contexts in Confluence or other plugins.

Information sourced from Plugin Framework documentation

Web UI Plugins

Web UI plugin modules allow you to insert links, tabs and sections of links into the Confluence web interface. They're not much use on their own, but when combined with XWork-WebWork Plugins they become a powerful way to add functionality to Confluence.

On this page:

- Sections and Items
- Locations
- Web Section Definition
- Web Item Definition
- Q and A
  - How do I make use of sections or web items in my own themes?
  - Can I create new locations for web UI plugins in my own themes?
  - If I create a Web Item that links to my custom action, how do I make it appear in the same tabs/context as the other items in that location?
  - My web UI link isn't appearing when I use the Adaptavist Theme Builder plugin - why?
  - The breadcrumb trail for my web UI administration/space administration/tab plugin is showing the class name - how do I fix it?

Sections and Items

Web UI plugins can consist of two kinds of plugin modules:

- Web Item modules define links that are to be displayed in the UI at a particular location.
- Web Section modules define a collection of links to be displayed together, in a 'section'.

Web items and web sections (referred to collectively as 'web fragments') may be displayed in a number of different ways, depending on the location of the fragment and the theme under which it is being displayed.

Locations

In a number of places in the Confluence UI, there are lists of links representing operations relevant to the content being viewed.

Please be aware that the Descriptions below relate to the default Confluence theme. Bold text used in each description relates to a component on the product interface.

These are the locations that you can customise:

<table>
<thead>
<tr>
<th>Location key</th>
<th>Themeable?</th>
<th>Sectioned?</th>
<th>Description</th>
<th>Availability</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Common Locations</strong></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Page-related</strong></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>system.attachment</td>
<td>✓</td>
<td>✗</td>
<td>The links on the right of an Attachments list</td>
<td>2.8</td>
</tr>
<tr>
<td>system.comment.action</td>
<td>✓</td>
<td>✓</td>
<td>The links within each comment listed at the end of pages and blogs. The sections include the primary section on the lower-left of a comment (i.e. the Edit, Remove and Reply links) and the secondary section on the lower-right (i.e. the Permanent link icon)</td>
<td>2.8</td>
</tr>
</tbody>
</table>
system.content.action ✔ ✔ ✔ The menu items on the Tools drop down menu available on pages and blogs. The sections of this menu include primary, marker, secondary and modify 2.8

User-related

system.profile ✔ ✔ ✔ The tabs above user profile views 2.2
system.profile.view ✔ ✔ ✔ These links are only visible to Confluence administrators and appear either beneath views of user profiles without personal spaces or beneath their own profile view. For example, Administer User 2.9
system.user ✔ ✔ ✔ The menu items on the 'username' drop down menu available in the top bar of all pages. The sections of this menu include user-preferences, user-content and user-operations 2.8

Other

system.content.add ✔ ✔ ✔ The menu items in the Add drop down menu available in pages, blogs and areas of the Space Admin and other Browse Space tabs. The sections of this menu include space and page 2.8
system.dashboard ✔ ✔ ✔ The action section on the lower-left of the global dashboard. This section appears below the Spaces list on this dashboard 2.10.2
system.labels ✔ ✔ ✔ The View sub-categories of the global All Labels / Popular Labels area 2.2

Space Admin and other Browse Space tabs

system.space ✔ ✔ ✔ The Space Admin and other Browse Space tabs 2.2
system.space.actions ✔ ✔ ✔ In versions of Confluence prior to and including version 2.9, these action icons appear in the top-right of most space-related views. However, from Confluence 2.10, this location key has been deprecated and has been superseded by 'system.content.add' 2.2
system.space.admin ✔ ✔ ✔ The links in the left-hand menu of the Space Admin tab area 2.2
system.space.advanced ✔ ✔ ✔ The links in the left-hand menu of the Advanced tab area 2.2
system.space.labels ✔ ✔ ✔ The View sub-categories of the Labels tab area 2.2
system.space.pages ✔ ✔ ✔ The View sub-categories of the Pages tab area 2.2

Administration Console

system.admin ✔ ✔ ✔ The links in the left-hand menu of the global Administration Console 2.2

- Those locations marked as being ‘themeable’ can be moved around, reformatted or omitted by Theme Plugins. The descriptions above refer to where they are located in the default theme.
- Locations marked as being 'sectioned' require that web items be grouped under web sections. In sectioned locations, web items that are not placed under a section will not be displayed.
- It is possible for themes to make any themeable locations sectioned, even when the default theme does not. We do not recommend this, as it would mean any plugin taking advantage of this would only be compatible with a particular theme.

Theme Compatibility
Themes based on Confluence versions prior to 2.2 will continue to function with Confluence 2.2, but will not be able to display any custom Web UI fragments until they are updated.

Web Section Definition
You may choose to create your own web sections or add to Confluence’s predefined ones, if it makes logical sense to do that.

Here is a sample atlassian-plugin.xml fragment for a web section:
Here is another sample:

The above example will create a new `section` on the 'Add' menu. You can then add a `web item` in the section. The location of this section depends on the relative weight compared to the other sections that have already been defined by Confluence or by other installed plugins.

Take a look at the full configuration of Web Section plugin modules.

The diagrams below illustrate the web sections available in the Confluence dropdown menus.

**Web sections for location system.content.action**

```
<web-section key="mail" name="Mail" location="system.space.admin" weight="300">
    <label key="space-mail" />
    <condition class="com.atlassian.confluence.plugin.descriptor.web.conditions.NotPersonalSpaceCondition"/>
</web-section>

<web-section key="page" name="Add Page Content" location="system.content.add" weight="200">
    <label key="page.word" />
</web-section>
```

**Web sections for location system.content.add**

**Web Item Definition**

Here's a sample `atlassian-plugin.xml` fragment for a web item:
Take a look at the full configuration of Web Item plugin modules.

**Q and A**

**How do I make use of sections or web items in my own themes?**

Take a look at how they are used in the default themes, you should be able to get a good idea of the necessary code. For example, here is some sample code from `space.vmd`:

Can I create new locations for web UI plugins in my own themes?

Yes. Just pick a new key for the `location` or `section` parameters of your plugin modules. By convention, you should probably use the standard 'inverted domain name' prefix so as not to clash with anyone else's plugins. We reserve all `system.*` locations for Confluence's core use.

Once again, however, we don't recommend this as you end up with plugins that are only useful in your own themes. Try to at least provide an alternative set of UI modules for people who are using other themes and still want to access the same functionality. You could, for example, define alternative UI plugin modules that placed your functions in Confluence's standard locations, but have a `<condition>` that disabled them in favour of your custom locations if your theme was installed.

If I create a Web Item that links to my custom action, how do I make it appear in the same tabs/context as the other items in that location?

The best way is to look at the .vm file of one of the existing items in that location. You are most interested in the `#applyDecorator` directive being called from that file. For example `viewpage.vm`, which defines the "View" tab in the `system.page` location has the following `#applyDecorator` directive:

If you were writing a plugin that was destined to be added as another item in the page tabs, your Velocity file for that action would also have to have a similar decorator directive around it:

Note that you should put your Web Item's plugin key as the 'mode'. This way, Confluence will make sure that the correct tab is highlighted as the active tab when people are viewing your action.

In some cases, such as the browse space tabs, you may have to use 'context' instead of 'mode'.

My web UI link isn't appearing when I use the Adaptavist Theme Builder plugin - why?

Theme Builder uses completely customisable navigation and as such can't automatically display web UI links because this would likely lead to duplication of many other, more common links.
You can, however use the \{menulink\} macro to insert any web UI link using the following notation:

\{menulink:webui|location=|key=|webui link|menulink\}

Theme Builder 2.0.8 and above now supports a growing number of third party plugins as standard - for more information see the online documentation. If you have a publicly available plugin and want an in-built menulink location for it, please contact Adaptavist.

The breadcrumb trail for my web UI administration/space administration/tab plugin is showing the class name — how do I fix it? In the atlassian-plugin.xml:

<!--Make sure each name is unique-->
<resource type="i18n" name="i18n-viewreview"
location="resources/ViewReviewAction" />

In the java:

//in an action
I18NBean i18NBean = getI18n();

//or in a macro or other sort of plugin
ThemeHelper helper = this.getHelper();
ConfluenceActionSupport action = (ConfluenceActionSupport)
helper.getAction();
Locale locale = action.getLocale();
I18NBean i18nBean = i18nBeanFactory.getI18NBean(locale);

//and
public void setI18NBeanFactory(I18NBeanFactory i18NBeanFactory)
{
	this.i18NBeanFactory = i18NBeanFactory;
}

Use a normal properties file and locate it as follows:

If we're talking about actions:
The properties file with the same name as the relevant action can go in the same directory as the action. So, if you had XYZAction.java, then XYZAction.properties could live in the same directory. And you would not have to do anything in the atlassian-plugin.xml file.

If you don’t want it to live there, or if you're not talking about an action:
Define a resource in the atlassian-plugin.xml and tell it to live wherever you want. The standard is resources.

• In the source: etc/resources
• In the jar: resources/

The property that handles the breadcrumb has to be the fully qualified name of the class plus .action.name

So, for a SharePointAdmin property you might use: com.atlassian.confluence.property you might use: com.atlassian.confluence.extra.sharepoint.SharePointAdmin.action.name=SharePoint Admin

Purpose of this Module Type

Web Item plugin modules allow plugins to define new links in application menus.

Configuration

The root element for the Web Item plugin module is `web-item`. It allows the following attributes and child elements for configuration:

Attributes

<table>
<thead>
<tr>
<th>Name</th>
<th>Required</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>class</td>
<td></td>
<td>The class which implements this plugin module. The class you need to provide depends on the module type. For example, Confluence theme, layout and colour-scheme modules can use classes already provided in Confluence. So you can write a theme-plugin without any Java code. But for macro and listener modules you need to write your own implementing class and include it in your plugin.</td>
<td></td>
</tr>
<tr>
<td>disabled</td>
<td></td>
<td>Indicate whether the plugin module should be disabled by default (value='true') or enabled by default (value='false').</td>
<td>false</td>
</tr>
<tr>
<td>i18n-name-key</td>
<td></td>
<td>The localisation key for the human-readable name of the plugin module.</td>
<td></td>
</tr>
<tr>
<td>key</td>
<td>☑️</td>
<td>The identifier of the plugin module. This key must be unique within the plugin where it is defined. A module with key <code>fred</code> in a plugin with key <code>com.example.modules</code> will have a complete key of <code>com.example.modules:fred</code>.</td>
<td>N/A</td>
</tr>
<tr>
<td>name</td>
<td></td>
<td>The human-readable name of the plugin module. Used only in the plugin’s administrative user interface.</td>
<td></td>
</tr>
<tr>
<td>section</td>
<td>☑️</td>
<td>Location into which this web item should be placed. For non-sectioned locations, this is just the location key. For sectioned locations it is the location key, followed by a slash ('/'), and the name of the web section in which it should appear.</td>
<td>N/A</td>
</tr>
<tr>
<td>system</td>
<td></td>
<td>Indicates whether this plugin module is a system plugin module (value='true') or not (value='false'). Only available for non-OSGi plugins.</td>
<td>false</td>
</tr>
<tr>
<td>weight</td>
<td></td>
<td>Determines the order in which web items appear. Items are displayed top to bottom or left to right in order of ascending weight. The 'lightest' weight is displayed first, the 'heaviest' weights sink to the bottom. The weights for most applications’ system sections start from 100, and the weights for the links generally start from 10. The weight is incremented by 10 for each in sequence so that there is ample space to insert your own sections and links.</td>
<td>1000</td>
</tr>
</tbody>
</table>

Elements

The table summarises the elements. The sections below contain further information.

<table>
<thead>
<tr>
<th>Name</th>
<th>Required</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>condition</td>
<td></td>
<td>Defines a condition that must be satisfied for the web item to be displayed. If you want to 'invert' a condition, add an attribute 'invert=true' to it. The web item will then be displayed if the condition returns false (not true).</td>
<td>N/A</td>
</tr>
<tr>
<td>conditions</td>
<td></td>
<td>Defines the logical operator type to evaluate its condition elements. By default 'AND' will be used.</td>
<td>AND</td>
</tr>
<tr>
<td>context-provider</td>
<td></td>
<td>Allows dynamic addition to the velocity context available for various web item elements (in XML descriptors only). Currently only one context-provider can be specified per web item and section.</td>
<td></td>
</tr>
<tr>
<td>description</td>
<td></td>
<td>The description of the plugin module. The 'key' attribute can be specified to declare a localisation key for the value instead of text in the element body. i.e. the description of the web item.</td>
<td></td>
</tr>
<tr>
<td>icon</td>
<td></td>
<td>Defines an icon to display with or as the link. Note: In some cases the icon element seems to be required. Try adding it if your web section is not displaying properly.</td>
<td>N/A</td>
</tr>
<tr>
<td>label</td>
<td>☑️</td>
<td>Is the i18n key that will be used to look up the textual representation of the link.</td>
<td>N/A</td>
</tr>
<tr>
<td>link</td>
<td>☑️</td>
<td>Defines where the web item should link to. The contents of the link element will be rendered using Velocity, allowing you to put dynamic content in links. For more complex examples of links, see below.</td>
<td>N/A</td>
</tr>
<tr>
<td>param</td>
<td></td>
<td>Parameters for the plugin module. Use the 'key' attribute to declare the parameter key, then specify the value in either the 'value' attribute or the element body. This element may be repeated. An example is the configuration link described in Adding a Configuration UI for your Plugin. This is handy if you want to use additional custom values from the UI.</td>
<td>N/A</td>
</tr>
<tr>
<td>resource</td>
<td></td>
<td>A resource for this plugin module. This element may be repeated. A 'resource' is a non-Java file that a plugin may need in order to operate. Refer to Adding Plugin and Module Resources for details on defining a resource.</td>
<td>N/A</td>
</tr>
</tbody>
</table>
tooltip  Is the i18n key that will be used to look up the textual mouse-over text of the link.  N/A

Label Elements

Label elements may contain optional parameters, as shown below:

```xml
<label key="common.concepts.create.new.issue">
  <param name="param0">$helper.project.name</param>
</label>
```

- The parameters allow you to insert values into the label using Java's `MessageFormat` syntax.
- Parameter names must start with `param` and will be mapped in alphabetical order to the substitutions in the format string. I.e. `param0` is `{0}`, `param1` is `{1}`, `param2` is `{2}`, etc.
- Parameter values are rendered using Velocity, allowing you to include dynamic content.

Tooltip Elements

Tooltip elements have the same attributes and parameters as the label elements. See above.

Link Elements

Link elements may contain additional information:

```xml
<link linkId="create_link">/secure/CreateIssue!default.jspa</link>
```

- The `linkId` is optional, and provides an XML id for the link being generated.

The body of the link element is its URL. The URL is rendered with Velocity, so you can include dynamic information in the link. For example, in Confluence, the following link would include the page ID:

```xml
<link linkId="view-attachments-link">/pages/viewpageattachments.action?pageId=$page.id</link>
```

Icon Elements

Icon elements have a `height` and a `width` attribute. The location of the icon is specified within a `link` element:

```xml
<icon height="16" width="16">
  <link>/images/icons/print.gif</link>
</icon>
```

Param Elements

Param elements represent a map of key/value pairs, where each entry corresponds to the param elements attribute: `name` and `value` respectively.

```xml
<param name="key" value="value" />
```

The value can be retrieved from within the Velocity view with the following code, where `$item` is a `WebItemModuleDescriptor`:

```velo
$item.webParams.get("key")  <!-- retrieve the value -->
$item.webParams.getRenderedParam("key", $user, $helper)  <!-- retrieve the Velocity rendered value -->
```

If the `value` attribute is not specified, the value will be set to the body of the element. I.e. the following two param elements are equivalent:
The context-provider element adds to the Velocity context available to the web section and web item modules. You can add what you need to the context, to build more flexible section and item elements. Currently only one context-provider can be specified per module. Additional context-providers are ignored.

The context-provider element must contain a class attribute with the fully-qualified name of a Java class. The referenced class:

* must implement `com.atlassian.plugin.web.ContextProvider`, and
* will be auto-wired by Spring before any additions to the Velocity context.

For example, the following context-provider will add `historyWindowHeight` and `filtersWindowHeight` to the context.

In the following example, `HeightContextProvider` extends `AbstractJiraContextProvider`, which is only available in JIRA and happens to implement `ContextProvider`. The `AbstractJiraContextProvider` conveniently extracts the `User` and `JiraHelper` from the context map, which you would otherwise have to do manually.

```java
public class HeightContextProvider extends AbstractJiraContextProvider
{
    private final ApplicationProperties applicationProperties;

    public HeightContextProvider(ApplicationProperties applicationProperties)
    {
        this.applicationProperties = applicationProperties;
    }

    public Map<String, Object> getContextMap(User user, JiraHelper jiraHelper)
    {
        if (jiraHelper != null && jiraHelper.getRequest() != null)
        {
            UserHistory history = (UserHistory) jiraHelper.getRequest().getSession().getAttribute(SessionKeys.USER_ISSUE_HISTORY);
            if (history != null)
            {
                int historyIssues = history.getIssues().size();
                int logoHeight = TextUtils.parseInt(applicationProperties.getDefaultBackedString(APKeys.JIRA_LF_LOGO_HEIGHT));
                String historyHeight = String.valueOf(80 + logoHeight + (25 * historyIssues));
                String filterHeight = String.valueOf(205 + logoHeight);
                return EasyMap.build("historyWindowHeight", historyHeight, "filtersWindowHeight", filterHeight);
            }
        }
        return null;
    }
}
```

The above `HeightContextProvider` can be used by nesting the following element in a web item module.

```xml
<context-provider class="com.atlassian.jira.plugin.web.contextproviders.HeightContextProvider" />
```

The newly added context entries `historyWindowHeight` and `filtersWindowHeight` can be used in the XML module descriptors just like normal velocity context variables, by prefixing them with the dollar symbol ($):

```xml
<web-item>
    <section>
        <value property="\$\{historyWindowHeight\}" />
    </section>
</web-item>
```
Condition and Conditions Elements

Conditions can be added to the web section and web item modules, to display them only when all the given conditions are true.

Condition elements must contain a class attribute with the fully-qualified name of a Java class. The referenced class:

- must implement `com.atlassian.plugin.web.Condition`, and
- will be auto-wired by Spring before any condition checks are performed.

Condition elements can take optional parameters. These parameters will be passed in to the condition's `init()` method as a map of string key/value pairs after autowiring, but before any condition checks are performed. For example:

```xml
<condition class="com.atlassian.jira.plugin.web.conditions.JiraGlobalPermissionCondition">
  <param name="permission">admin</param>
</condition>
```

To invert a condition, add the attribute `invert="true"` to the condition element. This is useful where you want to show the section if a certain condition is not satisfied.

Conditions elements are composed of a collection of condition/conditions elements and a type attribute. The type attribute defines what logical operator is used to evaluate its collection of condition elements. The type can be one of AND or OR.

For example: The following condition is true if the current user is a system administrator OR a project administrator:

```xml
<conditions type="OR">
  <condition class="com.atlassian.jira.plugin.web.conditions.JiraGlobalPermissionCondition">
    <param name="permission">admin</param>
  </condition>
  <condition class="com.atlassian.jira.plugin.web.conditions.UserHasProjectsCondition">
    <param name="permission">project</param>
  </condition>
</conditions>
```

Example

Here is an example atlassian-plugin.xml file containing a single web item:

```xml
<atlassian-plugin name="Hello World Plugin" key="example.plugin.helloworld" plugins-version="2">
  <plugin-info>
    <description>A basic web item module test</description>
    <vendor name="Atlassian Software Systems" url="http://www.atlassian.com"/>
    <version>1.0</version>
  </plugin-info>
  <web-item key="google_home" name="Google Home" section="system.admin/example1" weight="10">
    <description key="item.google.home.desc">Simple link to google.com.</description>
    <label key="item.google.home.label" />
    <link linkId="google_home">http://google.com</link>
  </web-item>
</atlassian-plugin>
```

Notes about Web Items in Confluence

Link elements

Here is another example of a Link elements containing additional information:
The accessKey is optional and provides an access key for the link being generated.

There is no standard way for Confluence to display a web item. Depending on where the item is being displayed, some information in the configuration may be ignored. For example, themes may choose not to display the icon, or may choose to display only the icon. Similarly, the linkId and accessKey attributes are only used in some locations.

Writing Confluence Plugins

Information sourced from Plugin Framework documentation

**Web Section Plugin Module**

On this page:
- Purpose of this Module Type
- Configuration
  - Attributes
  - Elements
  - Label Elements
  - Tooltip Elements
  - Param Elements
  - Context-provider Element
  - Condition and Conditions elements
- Example

**Purpose of this Module Type**

Web Section plugin modules allow plugins to define new sections in application menus. Each section can contain one or more links. To insert the links themselves, see the Web Item Plugin Module.

**Configuration**

The root element for the Web Section plugin module is `web-section`. It allows the following attributes and child elements for configuration:

**Attributes**

<table>
<thead>
<tr>
<th>Name</th>
<th>Required</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>class</td>
<td></td>
<td>The class which implements this plugin module. The class you need to provide depends on the module type. For example, Confluence theme, layout and colour-scheme modules can use classes already provided in Confluence. So you can write a theme-plugin without any Java code. But for macro and listener modules you need to write your own implementing class and include it in your plugin.</td>
<td></td>
</tr>
<tr>
<td>disabled</td>
<td></td>
<td>Indicate whether the plugin module should be disabled by default (value='true') or enabled by default (value='false').</td>
<td>false</td>
</tr>
<tr>
<td>i18n-name-key</td>
<td></td>
<td>The localisation key for the human-readable name of the plugin module.</td>
<td></td>
</tr>
<tr>
<td>key</td>
<td>✔️</td>
<td>The identifier of the plugin module. This key must be unique within the plugin where it is defined. A module with key fred in a plugin with key com.example.modules will have a complete key of com.example.modules:fred.</td>
<td>N/A</td>
</tr>
<tr>
<td>name</td>
<td></td>
<td>The human-readable name of the plugin module. Only used in the plugin's administrative user interface.</td>
<td></td>
</tr>
<tr>
<td>section</td>
<td>✔️</td>
<td>Location into which this web item should be placed. For non-sectioned locations, this is just the location key. For sectioned locations it is the location key, followed by a slash ('/'), and the name of the web section in which it should appear.</td>
<td>N/A</td>
</tr>
<tr>
<td>system</td>
<td></td>
<td>Indicates whether this plugin module is a system plugin module (value='true') or not (value='false'). Only available for non-OSGi plugins.</td>
<td>false</td>
</tr>
</tbody>
</table>
weight | Determines the order in which web items appear. Items are displayed top to bottom or left to right in order of ascending weight. The 'lightest' weight is displayed first, the 'heaviest' weights sink to the bottom. The weights for most applications' system sections start from 100, and the weights for their links generally start from 10. The weight is incremented by 10 for each in sequence so that there is ample space to insert your own sections and links. | N/A

Elements

The table summarises the elements. The sections below contain further information.

<table>
<thead>
<tr>
<th>Name</th>
<th>Required</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>condition</td>
<td></td>
<td>Defines a condition that must be satisfied for the web item to be displayed. If you want to 'invert' a condition, add an attribute 'invert=&quot;true&quot;' to it. The web item will then be displayed if the condition returns false (not true).</td>
<td>N/A</td>
</tr>
<tr>
<td>conditions</td>
<td></td>
<td>Defines the logical operator type used to evaluate the condition elements. By default 'AND' will be used.</td>
<td>AND</td>
</tr>
<tr>
<td>context-provider</td>
<td></td>
<td>Allows dynamic addition to the Velocity context available for various web item elements (in XML descriptors only). Currently only one context-provider can be specified per web item and section.</td>
<td>N/A</td>
</tr>
<tr>
<td>description</td>
<td></td>
<td>The description of the plugin module. The 'key' attribute can be specified to declare a localisation key for the value instead of text in the element body. Use this element to describe the section.</td>
<td></td>
</tr>
<tr>
<td>label</td>
<td></td>
<td>Is the i18n key that will be used to look up the textual representation of the link.</td>
<td>N/A</td>
</tr>
<tr>
<td>param</td>
<td></td>
<td>Parameters for the plugin module. Use the 'key' attribute to declare the parameter key, then specify the value in either the 'value' attribute or the element body. This element may be repeated. Defines a key/value pair available from the web item. This is handy if you want to use additional custom values from the UI.</td>
<td>N/A</td>
</tr>
<tr>
<td>resource</td>
<td></td>
<td>A resource for this plugin module. This element may be repeated. A 'resource' is a non-Java file that a plugin may need in order to operate. Refer to Adding Plugin and Module Resources for details on defining a resource.</td>
<td>N/A</td>
</tr>
<tr>
<td>tooltip</td>
<td></td>
<td>Is the i18n key that will be used to look up the textual mouse-over text of the link.</td>
<td>N/A</td>
</tr>
</tbody>
</table>

Label Elements

Label elements may contain optional parameters, as shown below:

```xml
<label key="common.concepts.create.new.issue">
  <param name="param0">$helper.project.name</param>
</label>
```

- The parameters allow you to insert values into the label using Java's MessageFormat syntax.
- Parameter names must start with `param` and will be mapped in alphabetical order to the substitutions in the format string. I.e. param0 is {0}, param1 is {1}, param2 is {2}, etc.
- Parameter values are rendered using Velocity, allowing you to include dynamic content.

Tooltip Elements

Tooltip elements have the same attributes and parameters as the label elements. See above.

Param Elements

Param elements represent a map of key/value pairs, where each entry corresponds to the param elements attribute: name and value respectively.

```xml
<param name="key" value="value" />
```

The value can be retrieved from within the Velocity view with the following code, where $item is a WebItemModuleDescriptor:
If the `value` attribute is not specified, the value will be set to the body of the element. I.e. the following two param elements are equivalent:

```html
<param name="isPopupLink" value="true" />
<param name="isPopupLink">true</param>
```

Context-provider Element

This feature only applies to JIRA

Only JIRA supports custom context providers.

The context-provider element adds to the Velocity context available to the `web` section and `web item` modules. You can add what you need to the context, to build more flexible section and item elements. Currently only one context-provider can be specified per module. Additional context-providers are ignored.

The `context-provider` element must contain a class attribute with the fully-qualified name of a Java class. The referenced class:

- must implement `com.atlassian.plugin.web.ContextProvider`, and
- will be auto-wired by Spring before any additions to the Velocity context.

For example, the following context-provider will add `historyWindowHeight` and `filtersWindowHeight` to the context.

In the following example, `HeightContextProvider` extends `AbstractJiraContextProvider`, which is only available in JIRA and happens to implement `ContextProvider`. The `AbstractJiraContextProvider` conveniently extracts the `User` and `JiraHelper` from the context map, which you would otherwise have to do manually.

```java
public class HeightContextProvider extends AbstractJiraContextProvider
{
    private final ApplicationProperties applicationProperties;

    public HeightContextProvider(ApplicationProperties applicationProperties)
    {
        this.applicationProperties = applicationProperties;
    }

    public Map getContextMap(User user, JiraHelper jiraHelper)
    {
        int historyIssues = 0;
        if (jiraHelper != null && jiraHelper.getRequest() != null)
        {
            UserHistory history = (UserHistory)
            jiraHelper.getRequest().getSession().getAttribute(SessionKeys.USER_ISSUE_HISTORY);
            if (history != null)
            {
                historyIssues = history.getIssues().size();
            }
        }

        int logoHeight =TextUtils.parseInt(applicationProperties.getDefaultBackedString(APKeys.JIRA_Vert_LOGO_HEIGHT));
        String historyHeight = String.valueOf(80 + logoHeight + (25 * historyIssues));
        String filtersHeight = String.valueOf(205 + logoHeight);
        return EasyMap.build("historyWindowHeight", historyHeight,
         "filtersWindowHeight", filterHeight);
    }
}
```

The above `HeightContextProvider` can be used by nesting the following element in a web item module.
The newly added context entries `historyWindowHeight` and `filtersWindowHeight` can be used in the XML module descriptors just like normal velocity context variables, by prefixing them with the dollar symbol ($):

```xml
<!-- pass the value of historyWindowHeight as a parameter called windowHeight (see param element above for its usage) -->
<param name="windowHeight">$historyWindowHeight</param>

<!-- set the link's label to print the value of filtersWindowHeight -->
<label>filter window height is: $filtersWindowHeight</label>
```

**Condition and Conditions elements**

Conditions can be added to the web section and web item modules, to display them only when all the given conditions are true.

Condition elements must contain a class attribute with the fully-qualified name of a Java class. The referenced class:

- must implement `com.atlassian.plugin.web.Condition`, and
- will be auto-wired by Spring before any condition checks are performed.

Condition elements can take optional parameters. These parameters will be passed in to the condition's `init()` method as a map of string key/value pairs after autowiring, but before any condition checks are performed. For example:

```xml
<condition class="com.atlassian.jira.plugin.web.conditions.JiraGlobalPermissionCondition">
  <param name="permission">admin</param>
</condition>
```

To invert a condition, add the attribute `invert="true"` to the condition element. This is useful where you want to show the section if a certain condition is not satisfied.

Conditions elements are composed of a collection of condition/conditions elements and a type attribute. The type attribute defines what logical operator is used to evaluate its collection of condition elements. The type can be one of `AND` or `OR`.

For example: The following condition is true if the current user is a system administrator OR a project administrator:

```xml
<conditions type="OR">
  <condition class="com.atlassian.jira.plugin.web.conditions.JiraGlobalPermissionCondition">
    <param name="permission">admin</param>
  </condition>
  <condition class="com.atlassian.jira.plugin.web.conditions.UserHasProjectsCondition">
    <param name="permission">project</param>
  </condition>
</conditions>
```

**Example**

Here is an example `atlassian-plugin.xml` file containing a single web section, using a condition that will be available in JIRA:
<atlassian-plugin name="Hello World Plugin" key="example.plugin.helloworld" plugins-version="2">
  <plugin-info>
    <description>A basic web section module test</description>
    <vendor name="Atlassian Software Systems" url="http://www.atlassian.com"/>
    <version>1.0</version>
  </plugin-info>
  <web-section key="usersgroups" name="Users and Groups Section" location="system.admin" weight="110">
    <label key="admin.menu.usersandgroups.users.and.groups"/>
    <condition class="com.atlassian.jira.plugin.web.conditions.UserIsAdminCondition"/>
  </web-section>
</atlassian-plugin>

Information sourced from Plugin Framework documentation

Workflow Plugins

This set of pages describes the Workflow Plugin. This is a work in progress and is useful as:

- An example of a reasonably complicated plugin, using macros, events and xwork actions which stores state as page properties and interacts with content entity versions and permissions.
- A starting point for discussion of what plugin-based workflow in Confluence might look like. A workflow implementation which made core Confluence changes might look different.

Here's a description of the workflow model implemented by the plugin.

Here's a [technical description] of the components of the Workflow Plugin.

⚠️ The workflow plugin as released in 1.4.2 does not have all the features described. It will be updated in the first 1.5DP release.

We're interested in getting feedback – how useful does the workflow model as described seem to you?

Workflow Plugin Prototype

Introduction

This page describes a prototype Workflow Plugin for Confluence. After reading it you should be able to create a workflow description and use it to manage a set of pages in Confluence.

The purposes of the Confluence Workflow Plugin Prototype are:

1. To provide a simple but usable workflow system for Confluence.
2. To solicit further requirements for Workflow in Confluence.
3. To demonstrate the power of the Confluence Plugin system – the workflow plugin did not require any changes to the core of Confluence.

The feature that this does not provide is the ability of different users to see different versions of a page. This is a problem for approval workflows, where we want an edit to remain invisible to ‘ordinary’ users until it has been approved.

I've also written up some ideas for a minimal Approval Workflow.

Plugin Information

You will need Java and Groovy development skills to implement this plugin. This is currently provided ‘as-is’ without Atlassian technical support, but you can search for or post questions relating to it in the Developer Forums. Alternatively, the Atlassian partner Saikore now offers paid support.

Workflow Concepts

This section describes the concepts used in building the Workflow Plugin.

Workflow Client
This is the entity whose life cycle is managed by the workflow plugin. In this implementation a client is a Confluence page. The client is responsible for remembering which workflow it is taking part in, remembering its workflow state, and changing this state when told to by the workflow system. A client may (and should) have other state information which is not visible to the workflow system, for instance the contents of a Confluence page are not managed by the workflow system at all.

Workflow Type

This is the set of data which defines a workflow. A workflow type is assembled from collections of States, Operations, Triggers and Actions.

Workflow State

At any time a Workflow Client is in one (and only one) State. This state determines which Operations are available to be performed on the client.

Operation

An Operation may be requested by the user on a Workflow Client. An Operation itself doesn't change any state, either in the workflow system or in the Workflow Client, but simply sends a signal to the Workflow Type that this Operation has been requested on that particular Workflow Client. It is just a description meaningful to a user, associated with a code meaningful to the Workflow Type, together with security rules to determine when the Operation can be performed. The signals sent to the Workflow Type may cause one or more Triggers to fire. Whether an Operation is available on a particular Client depends on the State of the client and the group membership of the current user. In addition to Operations defined in a particular Workflow Type, all Workflow Types recognize page edit and page view operations.

Trigger

A Trigger listens for Operations, and either fires or does not fire, depending on the Operation, its internal state (if any – many simple triggers are stateless) and its implementation. When a Trigger fires it tells the set of Actions it contains to execute.

Examples of Triggers are:
   1. Fire every time you receive a particular event.
   2. Fire after receiving any of a set of events.
   3. Fire after receiving all of a set of events, in any order. (This requires a Trigger which can maintain internal state)

Action

An Action is a piece of code which is executed in response to the firing of a Trigger.

Some Actions interact with the Workflow System:
   2. Create a new Trigger.
   3. Remove a Trigger.

Others interact with Confluence:
   1. Restrict Page Permissions
   2. Remove Page Permissions restriction.
   3. Send Notification to prior editor of page.

Others could interact with the contents of the page itself:
   1. Add 'Draft' warning to page contents.
   2. Validate field values in the page contents.

Using The Prototype Confluence Workflow Plugin

Build and Install the Workflow Plugin

From your Confluence install directory, go to plugins/workflow or access from the Confluence source under src/etc/plugins/workflow. Build the plugin into a JAR file.

Configure groups and permissions

Decide what groups will be involved in the workflow, create them and assign appropriate users to them. Grant suitable permissions to the space.

Create a WorkflowType

You need to create an instance of a class which implements com.atlassian.confluence.extra.workflow.WorkflowType, and register it by passing it to WorkflowManager.registerType().

One way to do this on a test basis is to put your workflow type in a (script) macro. The script macro can be downloaded from here. You’ll need to visit the page after restarting the server.

The example below uses a Groovy script – you could just as well use Beanshell, Jython or JRuby.
Put a `{workflowtype: yourWorkflowTypeName}` macro after your script, so you can see that it is properly creating the WorkflowType.

Create a Workflow Page

To make a page take part in the workflow you have just created, add the `{workflow: workflowTypeName}` macro to the page and hit Update.

You’ll get a workflow box with the option ‘Start Workflow’. Select this and the page will refresh. The workflow box will now indicate that the page is in the starting state for that workflow type.

Monitoring Workflow

You can use the `{workflowTasks}` macro to display a list of all workflow pages which are descendants of the current page. Any task which the viewing user can perform an action on will be starred.

To Do

1. More Trigger types.
3. Easy editing of WorkflowTypes.
4. Workflow of parent can depend on states of children
5. Introduce concept of 'Assignments', where at one workflow step a particular user is assigned to a role which nominates them to perform other operations.
6. Think about the visual style – the current style is good for when workflow is 'out of band', that is, it's an activity undertaken by site maintainers invisible to site users, but doesn't suit a 'Confluence as web-app' application, where workflow should blend in...

Approval Workflow

This page describes the details of an approval workflow.

- Users may be members of an 'author' group which is allowed to edit pages, an 'approver' group which is allowed to approve edited pages, or both groups (in which case they can't approve their own changes) or neither (in which case they are just consumers of the content).
- When an 'author' edits a page, the page goes into a 'editing in progress' state.
- When an author views an 'editing in progress' page, they are presented with an option to submit the page for review. This puts the page into the 'waiting for approval' state.
- Members of the approver group have access to a page in confluence which automatically lists the pages waiting for approval.
- When an 'approver' visits a 'waiting for approval' page, they are presented with options to accept or reject the changes. If they accept the changes, the page goes to the 'accepted' state, where pages spend most of their life, otherwise it goes to the 'rejected' state.
- Members of the 'author' group have access to a page in Confluence where they can see all the pages which they edited which have been rejected, or are waiting for approval. They don't see pages other authors have edited.
- When an author visits a page in the 'rejected' or 'waiting for approval' state, they have the option of withdrawing the change, which moves the page to the accepted state, and rolls back to the most recent approved version.
- When an author edits a page in the rejected state, it moves to the 'editing in progress' state.

All of this can be done with the Workflow Plugin Prototype.

But we probably also want to show consumers the most recently approved version of a page, not the one currently under review. Without core Confluence changes, the best we can do is show users a banner which says "This content is being reviewed. The most recent approved content is here".

XWork-WebWork Plugins

XWork plugin modules enable you to deploy XWork / WebWork actions and views as a part of your plugins.

- For more information about plugins in general, read Confluence Plugin Guide.
- To learn how to install and configure plugins (including macros), read Installing and Configuring Plugins Manually.
- For an introduction to writing your own plugins, read Writing Confluence Plugins

The XWork Plugin Module

Each XWork module is deployed as a plugin module of type xwork and contains one or more XWork package elements.

Here is an example atlassian-plugin.xml file containing a single XWork module:

```xml
<atlassian-plugin name='List Search Macros' key='confluence.extra.livesearch'>
    ...
    <xwork name='livesearchaction' key='livesearchaction'>
        <package name='livesearch' extends='default' namespace="/plugins/livesearch">
            <default-interceptor-ref name='defaultStack' />  
            <action name='livesearch' class='com.atlassian.confluence.extra.livesearch.LiveSearchAction'>  
                <result name='success' type='velocity'>/templates/extra/livesearch/livesearchaction.vm</result>
            </action>
        </package>
    </xwork>
</atlassian-plugin>
```

- the xwork element has no class attribute.
- beneath this element, multiple package elements can be specified. These are standard XWork package elements, just as you would specify in xwork.xml.
Writing an Action

For information on how to write a WebWork action, please consult the WebWork documentation. WebWork actions must implement com.opensymphony.xwork.Action. However, we recommend you make your action extend ConfluenceActionSupport, which provides a number of helper methods and components that are useful when writing an Action that works within Confluence.

Other action base-classes can be found within Confluence, but we recommend you don't use them - the hierarchy of action classes in Confluence is over-complicated, and likely to be simplified in the future in a way that will break your plugins.

Accessing Your Actions

Actions are added to the XWork core configuration within Confluence, which means they are accessed like any other action!

For example, given the above atlassian-plugin.xml, the livesearch action would be accessed at http://yourserver/confluence/plugins/livesearch/livesearch.action.

Notes

Some issues to be aware of when developing or configuring an XWork plugin:

- Your packages should always extend the default Confluence package. It is useful to be aware of what this provides to you in the way of interceptors and result types. Extending any other package will modify that package's configuration across the entire application, which is not supported or desirable.
- You can give your packages any namespace you like, but we recommend using /plugins/unique/value that is prefixing plugin packages with /plugins and then adding a string globally unique to your plugin. The only name you can use is servlet as the /plugins/servlet URL pattern is reserved for Servlet Plugins.
- Views must be bundled in the JAR file in order to be used by your actions. This almost always means using Velocity views.
- It is useful to be aware of the actions and features already bundled with Confluence, for example your actions will all be auto-wired by Spring (see Accessing Confluence Components From Plugin Modules) and your actions can use useful interfaces like PageAware and SpaceAware to reduce the amount of work they need to do.

Important Security Note

If you are writing an XWork plugin, it is very important that you read this security information: XWork Plugin Complex Parameters and Security.

Example

The LiveSearch example is a neat example of an Ajax-style Confluence plugin which uses a bundled XWork module to do it's work:

Find this example in the /plugins/macros/livesearch directory within your Confluence distribution.

XWork Plugin Complex Parameters and Security

This document describes changes that were made to the handling of XWork plugins in Confluence between versions 2.9 and 2.10. All developers writing XWork plugins for Confluence 2.10 and later should take note of this.

Complex XWork Parameters

XWork allows the setting of complex parameters on an XWork action object. For example, a URL parameter of formData.name=Charles will be translated by XWork into the method calls getFormData().setName("Charles") by the XWork parameters interceptor. If getFormData() returns null, XWork will attempt to create a new object of the appropriate return type using its default constructor, and then set it with setFormData(newObject).

This leads to the potential for serious security vulnerabilities in XWork actions, as you can effectively call arbitrary methods on an Action object. This led to the Parameter Injection issues in Confluence Security Advisory 2008-10-14. In Confluence 2.9 this issue was worked around by filtering out all properties that were known to be dangerous, but for 2.10 a more complete solution that also protects against future vulnerabilities has been introduced.

Because this vulnerability (and its solution) can affect plugins, plugin authors must now take extra steps to support complex form parameters.

The @ParameterSafe Annotation

From Confluence 2.10 and onwards, complex parameters are not permitted unless they are accompanied by a Java-level annotation declaring that the parameter is "safe" for XWork to access. There are two ways to apply the annotation:

- If a getter method is annotated with the @com.atlassian.xwork.ParameterSafe annotation, that method is accessible as a complex parameter
- If a class is annotated with the @com.atlassian.xwork.ParameterSafe annotation, any complex parameter that is of that type is accessible

Only the initial method on the XWork action, or initial return value from the action class needs to be annotated, nested complex parameters
do not need further annotation.

So in the example above, to make the formData parameter you would do one of the following:

```java
@ParameterSafe
class FormData {
    ...  
}
```

or:

```java
@ParameterSafe
class FormData {
    ...  
}
```

**Be Careful**

By placing the `@ParameterSafe` annotation on a method or class, you the developer are declaring that you have carefully inspected that code for potential vulnerabilities. Things to be careful of:

- **DO NOT** return live Hibernate persistent objects, as users may change values on them directly with parameters, and then those changes will be saved to the database automatically
- **DO NOT** return objects that contain setter methods that are used for anything but setting form parameter values, as those values will be reachable by URL parameter injection
- **DO NOT** return objects that have Spring-managed beans, live components, or Hibernate objects accessible through getter methods, as they will be accessible to URL parameter injection

Your safest bet is that if you are using an object to store complex parameters, make it a dumb: just setters that store state in the object itself and no further behaviour. Any more functionality than that is dangerous.

### Accessing Confluence Components From Plugin Modules

Confluence is built around *Spring*, an open-source component framework for Java. If you are familiar with Spring, then you may only wish to know that Confluence plugin modules (and their implementing classes) are autowired by name. Thus, if you want to access a Confluence component from your plugin, just include the appropriate setter method in your implementing class.

If you want to write Confluence plugins but are unfamiliar with Spring, the rest of this page should give you more than enough information on how to have your plugin interact with Confluence.

**Interacting with Confluence**

When you are writing anything but the simplest Confluence plugin, you will need to interact with the Confluence application itself in order to retrieve, change or store information. This document describes how this can be done.

#### Manager Objects

At the core of Confluence is a group of “Manager” objects. For example, the `pageManager` is in charge of Confluence pages, the `spaceManager` of spaces, the `attachmentManager` of attachments, and so on.

#### Dependency Injection

Traditionally, in a component-based system, components are retrieved from some kind of central repository. For example, in an EJB-based system, you would retrieve the bean from the application server's JNDI repository.

Confluence works the other way round. When a plugin module is instantiated, Confluence determines which components the module needs, and delivers them to it.

Confluence determines which components a module needs by reflecting on the module's methods. Any method with a signature that matches a standard JavaBeans-style setter of the same name as a Confluence component will have that component passed to it when the module is initialised.

So, if your plugin module needs to access the `pageManager`, all you need to do is put the following setter method on your module's implementing class:

```java
public void setPageManager(PageManager pageManager)
{
    this.pageManager = pageManager;
}
```

#### Manager Classes
There are several dozen managers for different areas of functionality in Confluence. The following table lists some of the more commonly used ones:

<table>
<thead>
<tr>
<th>Manager class</th>
<th>Responsibility</th>
<th>Sample methods</th>
</tr>
</thead>
<tbody>
<tr>
<td>PageManager</td>
<td>Pages, blogs</td>
<td>getPage(), getBlogPost(), getRecentlyAddedPages(), findNextBlogPost(), saveContentEntity()</td>
</tr>
<tr>
<td>SpaceManager</td>
<td>Spaces</td>
<td>getSpace(), getPersonalSpace(), createSpace()</td>
</tr>
<tr>
<td>UserAccessor</td>
<td>Users, groups, preferences</td>
<td>getUser(), addUser(), addMembership(), hasMembership(), getConfluenceUserPreferences(), getUserProfilePicture()</td>
</tr>
<tr>
<td>CommentManager</td>
<td>Comments</td>
<td>getComment(), updateCommentContent()</td>
</tr>
<tr>
<td>LabelManager</td>
<td>Labels</td>
<td>addLabel(), removeLabel(), getCurrentContentForLabel()</td>
</tr>
<tr>
<td>AttachmentManager</td>
<td>Attachment storage and retrieval</td>
<td>getAttachments(Content), getAttachmentData(Attachment), saveAttachment()</td>
</tr>
<tr>
<td>SmartListManager</td>
<td>Searching (2.8 and earlier)</td>
<td>getListQueryResults()</td>
</tr>
<tr>
<td>SearchManager</td>
<td>Searching (2.9 and later)</td>
<td>search(), convertToEntities(), searchEntities()</td>
</tr>
<tr>
<td>ContentEntityManager</td>
<td>Saving and retrieving all content. Parent interface of PageManager, CommentManager, etc.</td>
<td>saveContentEntity(), getVersionHistorySummaries()</td>
</tr>
<tr>
<td>SettingsManager</td>
<td>Global, space, plugin configuration</td>
<td>getGlobalSettings(), updateSpaceSettings(), getPluginSettings()</td>
</tr>
<tr>
<td>I18NBean</td>
<td>Getting localised text</td>
<td>getText(String), getText(String, Object[]), getText(String, List)</td>
</tr>
<tr>
<td>PermissionManager</td>
<td>Checking permissions (do this before calling a manager)</td>
<td>hasPermission(), hasCreatePermission(), isConfluenceAdministrator(), getPermittedEntities()</td>
</tr>
<tr>
<td>SpacePermissionManager</td>
<td>Adding or modifying space permissions</td>
<td>savePermission(), getGlobalPermissions(), getGroupsWithPermissions()</td>
</tr>
<tr>
<td>EventManager</td>
<td>Register listeners or publish events</td>
<td>publishEvent(), registerListener()</td>
</tr>
<tr>
<td>WebInterfaceManager</td>
<td>Rendering web-sections and web-items in Velocity</td>
<td>getDisplayableSections(), getDisplayableItems()</td>
</tr>
</tbody>
</table>

Note that these are all interfaces. The actual implementation will be injected in your class by Spring, if you include the appropriate setter method in your class as described above.

Do not directly use implementations or cast the injected class to a particular implementation. Implementation classes are subject to change across versions without warning. Where possible, interface methods will be marked as deprecated for two major versions before being removed.

**Service Classes**

Managers in Confluence are responsible for the data integrity of their domain, but they are not generally responsible for validation or security. Invalid calls will typically result in a runtime exception. Historically, this wasn’t a major problem, but as time went by there was more duplication of this functionality across actions, remote API methods and plugins. In recent releases, a service layer is being introduced in Confluence to address this.

The services will follow a command pattern, where the service is responsible for creating a command that can then be validated and executed. The following nascent services are available:

<table>
<thead>
<tr>
<th>Service class</th>
<th>Responsibility</th>
<th>Sample commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>CommentService</td>
<td>Comments</td>
<td>CreateCommentCommand, DeleteCommentCommand, EditCommentCommand</td>
</tr>
<tr>
<td>PageService</td>
<td>Pages, blog posts</td>
<td>MovePageCommand</td>
</tr>
<tr>
<td>SearchService (2.9+)</td>
<td>Performing searches</td>
<td></td>
</tr>
</tbody>
</table>

These simpler services don’t follow the command pattern, nor do they perform any data modification. They are generally used to simplify other functionality:

<table>
<thead>
<tr>
<th>Service class</th>
<th>Responsibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>HttpRetrievalService</td>
<td>Http Connectivity to External Services</td>
</tr>
</tbody>
</table>
Including Javascript and CSS resources

Good style for web applications requires that JavaScript and CSS for web pages are kept separate to the HTML they enhance. Confluence itself is moving towards this model, and the tools that Confluence uses to do this are also available to plugin developers.

This functionality is only available in Confluence 2.8 and later.

If you are developing a theme plugin and would like to include css resources, see Theme Stylesheets instead.

On this page:
- Including a Custom JavaScript or CSS File from a Plugin
- Web Resource Configuration
- Including a JavaScript Library provided by Confluence
- Running Scripts when the Page Loads
- Achieving Progressive Enhancement
- More Information

Including a Custom JavaScript or CSS File from a Plugin

In your `atlassian-plugin.xml`, you should add a Web Resource module. See Web Resource Plugins.

For each resource, the location of the resource should match the path to the resource in your plugin JAR file. Resource paths are namedpaced to your plugin, so they can't conflict with resources in other plugins with the same location (unike say i18n or Velocity resources). However, you may find it convenient to use a path name which is specific to your plugin to be consistent with these other types.

To include your custom web resource in a page where your plugin is used, you use the `#requireResource` Velocity macro like this:

```
#requireResource("com.acme.example.plugin:web-resource-key")
```

Where "com.acme.example.plugin:web-resource-key" should be your plugin key, a colon, and the key of the web resource module in your plugin.

Only one instance of each script or stylesheet will be included, and they will appear in the order they are requested in the Velocity rendering process.

The rich text editor does not currently use dynamic stylesheets provided by a macro rendered in this way.

Web Resource Configuration

Within your Web Resource plugin module, you will define one or more resource definitions. See Adding Plugin and Module Resources.

Note that you can declare the media type (for CSS resources) and whether the resource should be wrapped in an Internet Explorer conditional comment. This feature is also described in Adding Plugin and Module Resources.

Here is a short example:

```
<web-resource key="my-macro-resources">
    <resource type="download" name="macro.js" location="path/inside/jar/to/js/macro.js"/>
    <resource type="download" name="more-macro-stuff.js" location="path/inside/jar/to/js/more-macro-stuff.js"/>
    <resource type="download" name="macro.css" location="path/inside/jar/to/css/macro.css"/>
    <resource type="download" name="macro-ie.css" location="path/inside/jar/to/css/macro-ie.css">
        <param name="ieonly" value="true"/>
        <param name="title" value="IE styles for My Awesome Macro"/>
    </resource>
    <resource type="download" name="macro-print.css" location="path/inside/jar/to/css/macro-print.css">
        <param name="media" value="print"/>
    </resource>
    <dependency>confluence.web.resources:ajs</dependency> <!-- depends on jQuery/AJS -->
</web-resource>
```

See below for the libraries provided by Confluence which you can include as a dependency.
Including a JavaScript Library provided by Confluence

Confluence currently includes several JavaScript libraries which plugins can use. The versions of these libraries are subject to change, but only across major versions of Confluence.

In the Confluence source code, these libraries are included in a plugin XML file called `web-resources.xml`.

<table>
<thead>
<tr>
<th>Library</th>
<th>Web resource key</th>
<th>Current version</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>jQuery + AJS</td>
<td>confluence.web.resources:ajs</td>
<td>1.2.6</td>
<td>Atlassian's JS abstraction on top of jQuery provides a few additional pieces of functionality.</td>
</tr>
<tr>
<td>jQuery</td>
<td>confluence.web.resources:jquery</td>
<td>1.2.6</td>
<td>For compatibility with prototype, you must use <code>jQuery()</code> not <code>$</code> to access jQuery.</td>
</tr>
</tbody>
</table>

To include one of these libraries in all pages in which your Velocity template appear, simply use the `#requireResource` macro as above. For example, if your macro requires jQuery, add the following to its Velocity template:

```
#requireResource("confluence.web.resources:jquery")
```

Deprecated libraries

Use of Scriptaculous, Prototype and DWR is deprecated. Use of these libraries in Confluence core will be gradually replaced with jQuery over the next few releases. Plugin developers should start doing the same with their front-end code, because these libraries will at some point, be removed in a future release of Confluence.

The 'Prototype' and 'Scriptaculous' libraries will no longer be available in Confluence 3.1.

<table>
<thead>
<tr>
<th>Library</th>
<th>Web resource key</th>
<th>Current version</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scriptaculous</td>
<td>confluence.web.resources:scriptaculous</td>
<td>1.5rc3</td>
<td>Deprecated. Do not use. Includes effects, dragdrop, controls and util.</td>
</tr>
<tr>
<td>Prototype</td>
<td>confluence.web.resources:prototype</td>
<td>1.4.0_pre11</td>
<td>Deprecated. Do not use. Version found in the scriptaculous lib directory. Also includes a domready extension, see domready.js.</td>
</tr>
<tr>
<td>DWR</td>
<td>confluence.web.resources:dwr</td>
<td>1.1.4</td>
<td>Deprecated. Do not use. Includes engine and util.</td>
</tr>
</tbody>
</table>

Running Scripts when the Page Loads

The recommended way to load scripts when the page is ready, known as 'on-DOM-ready', is to use the Atlassian JavaScript (AJS) abstraction. This avoids depending on a particular JavaScript library which may not remain in Confluence.

```
AJS.toInit(function () {
  // ... your initialisation code here
});
```

This has the additional benefit of ensuring any functions or variables you declare here are not in the global scope, which is important for best interoperability with other plugins in Confluence.

Achieving Progressive Enhancement

We recommend you separate your markup, styles and JavaScript when developing a Confluence plugin, according to the design principles of progressive enhancement. To assist with this, there are a few hooks in AJS and in Confluence in general to make this easier.

Dynamic Content in JavaScript

If you need to pass information from Velocity to JavaScript, such as for localised text, you can use `AJS.params`. This automatically looks up values inside fieldsets marked with a class of "parameters" inside your markup. For example, given the following markup:

```
<fieldset class="parameters hidden">
  <input type="hidden" id="deleteCommentConfirmMessage" value="%action.getText('remove.comment.confirmation.message')">
</fieldset>
```

You can have your JavaScript access the localised text without embedding it by using `AJS.params`:

```
AJS.toInit(function () {
  // ... your initialisation code here
});
```
Getting the Context Path

Usually, you can use relative paths in stylesheets and JavaScript to avoid the need to know the context path. However, Confluence makes this available through a meta tag in the header which looks like this:

```html
<meta id="confluence-context-path" name="confluence-context-path" content="/confluence">
```

With jQuery, or even normal JavaScript, it is quite easy to retrieve this for use in scripts:

```javascript
// normal JS
var relativeUrl = (document.getElementById("confluence-context-path").content || ") + "/path/to/content"

// jQuery
var relativeUrl = ($("#confluence-context-path").attr("content") || ") + "/path/to/content";
```

More Information

Could you do this already? What's changed in Confluence 2.8?

Since Confluence 2.6, you've been able to use `#includeJavascript`, which puts the script tag inline, exactly where that Velocity macro appears. You've also always been able to include inline scripts or styles in your macros. However, there are a couple of problems with this that we've solved in 2.8:

1. The JavaScript might override other script already present in the page, including scripts used by Confluence.
2. Inline JavaScript or styles might appear multiple times in the page, wasting bandwidth and potentially causing conflicts.

Many plugin authors found that including JavaScript in their plugins meant the plugin broke in some places, such as in the preview window, if two copies of the macro were on the same page.

By using the new `#requireResource`, you're guaranteed to get only one instance of the script appearing on a page, and it will be cached by browsers until your plugin is upgraded.

Do I have to use Velocity to request these resources? What about in Java?

You can achieve the same result in Java via the WebResourceManager. Use the same method as described above for Velocity:

```java
webResourceManager.requireResource(String)
```

The WebResourceManager is a bean you can get injected by Spring. Do this within the scope of the request.

In most cases, using Velocity makes more sense, because the declaration of the JS and CSS should be close to the code which uses it.

Installing and Configuring Plugins Manually

Adding Plugin and Module Resources

Confluence plugins may define downloadable resources. If your plugin requires Confluence to serve additional static files such as images, JavaScript or CSS, you will need to use downloadable plugin resources to make them available.

On this page:

- Purpose of a Resource
- Example of a Resource Definition
- Contents of the Resource Definition
- Example of Resource Type: Downloadable Plugin Resources
- Example of Resource Type: Stylesheet referring to Images
- Values for Param Element

Purpose of a Resource

A 'resource' is a non-Java file that a plugin may need in order to operate. Examples of possible resources might be:

- A Velocity file used to generate HTML for a macro or layout plugin module in Confluence.
- A CSS file required by a theme layout plugin module.
- An image referenced from within a layout plugin module.
- A macro help file.
A localisation property file.

Resource definitions can be either a part of the plugin, or part of a particular plugin module.

**Example of a Resource Definition**

Here is a sample resource definition:

```xml
<!-- A resource has a type, a name and a location. The resource definition maps -->
<!-- some arbitrary resource name to where that resource would be located in    -->
<!-- the server's classpath -->
<resource type="velocity" name="template" location="com/example/plugin/template.vm"/>

<!-- For the localisation property file below, it must be named exampleplugin.properties -->
<!-- located under the resources folder -->
<resource type="i18n" name="i18n" location="resources/exampleplugin"/>

<!-- Resources may contain arbitrary key/value pairs -->
<resource type="download" name="style.css" location="com/example/plugin/style.css">
    <property key="content-type" value="text/css"/>
</resource>
```

**Contents of the Resource Definition**

A resource has a name, a type and a location. The resource definition maps an arbitrary resource name to the location of that resource in the server's classpath.

<table>
<thead>
<tr>
<th>Element</th>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;resource&gt;</td>
<td></td>
<td>This block defines the resource. For example: <code>&lt;resource type=&quot;velocity&quot; name=&quot;template&quot; location=&quot;com/example/plugin/template.vm&quot;/&gt;</code></td>
</tr>
</tbody>
</table>
| <resource> | name      | The name of the resource defines how the plugin module can locate a particular resource. Must be specified if 'namePattern' is not. If your location parameter points to a directory rather than a single resource, you should specify the name with a trailing '/'. For example: `<resource type="download" name="myimages/" location="com/example/plugin/myimages"/>

Note that for css/javascript resources, they must have the appropriate file extension in the name i.e. `.css`, `.js` |
| <resource> | namePattern | The pattern to use when loading a directory resource. |
| <resource> | type      | The type of a resource tells the module how that resource can be used. The values allowed are different for each application. A module can look for resources of a certain type or name. For example, a layout plugin requires that its help file is a file of type velocity and name help. Refer to the examples of resource types below. |
| <resource> | location  | The location of a resource tells the plugin where the resource can be found in the jar file. (Resources are loaded by Java's classpath resource loader.)

- The full path to the file (without a leading slash) is required.
- Must end in a '/' when using the 'namePattern' attribute to load multiple resources in a directory. |
| <property> | key/value | Resources may contain arbitrary key/value pairs. For example: `<property key="content-type" value="text/css"/>` |
| <param>    | name/value | Resources may contain arbitrary name/value pairs. For example: `<param name="content-type" value="image/gif"/>`. Refer to the list of values for the param element below |

**Example of Resource Type: Downloadable Plugin Resources**

The simplest kind of resource, supported with all plugin module types, is of type download, which makes a resource available for download from the application at a particular URL.

```xml
<resource type="download" name="aimon.gif" location="templates/extra/impressence/aimon.gif">
    <param name="content-type" value="image/gif"/>
</resource>
```

See Downloadable Plugin Resources.

**Example of Resource Type: Stylesheet referring to Images**

```xml
<resource type="download" name="style.css" location="com/example/plugin/style.css">
    <property key="content-type" value="text/css"/>
</resource>
```
Stylesheets for your plugin may often refer to images also in your plugin. In which case you would have to make both the stylesheet and image(s) downloadable.

```xml
<resource type="download" name="my-images/" location="com/example/plugin/myimages"/>
<resource type="download" name="my-style.css" location="com/example/plugin/my-style.css"/>
```

Note: If you have multiple stylesheets and javascript resources defined, you should put the resource definitions in a Web Resource Module.

To refer to your plugin images in a stylesheet, use a relative path based on the resource name defined for the image (which is 'my-images' in this case).

```css
.my-class {
  background-image: url(my-images/mypicture.gif);
}
```

To reference images already available in an application, you will need to go up three parent directories like so:

```css
.my-class {
  background-image: url(../../../images/icons/confluence-logo.gif);
}
```

**Values for Param Element**

These are the common name/value pairs supported by the `<param>` element.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value (Example)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>content-type</td>
<td>image/gif</td>
<td>Specify a MIME content type.</td>
</tr>
<tr>
<td>media</td>
<td>print</td>
<td>Declare the media type for CSS resources. This is supported by Web Resource plugin modules. For example, requesting this resource will insert a <code>&lt;link&gt;</code> in the HTML header, with a media value of 'print':</td>
</tr>
</tbody>
</table>

```xml
<web-resource key="mechanical-parts" name="Mechanical Parts">
  <i18n-name-key=com.example.confluence.plugin.special.mechanical.parts.name/>
  <resource type="download" name="sprockets.css" location="styles/sprockets.css">
    <param name="media" value="print"/>
  </resource>
</web-resource>
```
ieonly true

Specify that the resource should be wrapped in an Internet Explorer conditional comment. This is supported by V modules.

For example, the web resource declaration below says that the resource should be wrapped in an Internet Explorer conditional comment, which means it will only be used by Internet Explorer. This is useful for IE-specific styling to work around browser bugs.

```xml
<web-resource key="mechanical-parts" name="Mechanical Parts"
i18n-name-key="com.example.confluence.plugin.special.mechanical.parts.name">
  <resource type="download" name="sprockets-ie.css" location="styles/sprockets.css">
    <param name="ieonly" value="true"/>
  </resource>
</web-resource>
```

The HTML output when this resource is included will be something like this:

```html
<!--[if IE]>
<link type="text/css" rel="stylesheet" media="all"
href="/s/1418/13/1.0/_/download/resources/plugin.example:mechanical-parts/sprockets-ie.css"/>
<![endif]-->
```

The `ieonly` parameter also works for JavaScript resources.

<table>
<thead>
<tr>
<th>title</th>
<th>(Your title)</th>
</tr>
</thead>
<tbody>
<tr>
<td>The value given here will form the title attribute of the CSS <code>&lt;link&gt;</code> tag.</td>
<td></td>
</tr>
</tbody>
</table>

- Notes

Purpose of the Configuration UI

A plugin for an Atlassian application can specify internal links within the application, to allow the user to configure options for the plugin. This is useful where your plugin requires configuration or user-specific settings to work.

Here are some examples of plugins which provide a configuration UI:

- The Google Maps plugin for Confluence requires a Google API Key from Google, which needs to be configured on each server, before it will work properly.
- The WebDAV plugin for Confluence provides a configuration screen that is available both from the Plugin Manager and from a web item in the Administration menu.

In Creating your Plugin Descriptor, we tell you how to create the XML descriptor file for your plugin. In Plugin Module Types, we tell you how to define the modules within your plugin. Below is information on defining the links to the configuration UI for your plugin.

Adding a Configuration Link for the Entire Plugin

To add a configuration link for your plugin as a whole, place a single `<param>` element with the name `configure.url` within the
**Adding a Configuration Link for a Module**

To add a configuration link for a single module within your plugin, place a single `<param>` element with the name `configure.url` within the descriptor element for that module:

```
<param name="configure.url">/admin/plugins/gmaps/configureMacro.action</param>
```

**Example of a Plugin Configuration UI**

Here is an image showing where the configuration links appear for both a plugin and an individual module within Confluence:

<td>Configure plugin</td>
</tr>
<tr>
<td></td>
<td>Disable plugin</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Notes**

- You can provide configuration links for a whole plugin and/or for any module within a plugin.
- Configuration links are relative to the application.
- The configuration URL is a link to a separate page, which you have defined using one of the following:
  - A new XWork action that you have defined via an XWork plugin module.
  - Or a servlet defined via a *Servlet* plugin module.
- Not all host applications support configuration links, so you may need to create a web item link in the administration menu to link to your configuration page.

Information sourced from Plugin Framework documentation

**Ensuring Standard Page Decoration in your Plugin UI**
On this page:

- Purpose of the Standard Page Decorators
- Specifying a Decorator
- Limitations on Standard Page Decoration in Confluence

**Purpose of the Standard Page Decorators**

Atlassian applications which support Plugin Framework 2.1 and later will also support standard page decorators. This allows your plugin to generate new web pages with consistent decoration by the host application across the Atlassian products.

**Specifying a Decorator**

Specify the decorator with an HTML `meta` tag in your `head` element:

```html
<html>
<head>
  <meta name="decorator" content="atl.general"/>
</head>
```

The following decorators are available:

- `atl.admin` for application administration pages.
- `atl.general` for the header and footer of general pages outside the administration UI.

**Limitations on Standard Page Decoration in Confluence**

In this version of Confluence, the standard page decorators are only available on the following URL patterns:

- `*.action`
- `*.vm`
- `/display/*`
- `/label/*`

Other URLs do not pass through the Sitemesh decoration filter, so the HTML they return will not be decorated.

**Making your Plugin Modules State Aware**

**Description**

The `StateAware` interface can be implemented by plugin modules which need to know when they are enabled or disabled.

**Implementation**

To be notified of enablement/disablement, implement the following in your `Macro Plugins`, `EventListener Plugins` or `Component Plugins`:

```java
public class YourMacro extends BaseMacro implements com.atlassian.plugin.StateAware
```

This has two methods you must implement:
public void enabled()
{
    // Your enablement code goes here.
}

public void disabled()
{
    // Your disablement code goes here.
}

**Call Sequence**

These methods are called in the following circumstances:

**enabled()**
1. At server startup, if the plugin is already installed and enabled.
2. If the plugin is installed via uploading.
3. If the plugin is enabled after having been disabled.
4. If the specific module is enabled after having been disabled.

**disabled()**
1. At server shutdown, if the plugin is installed and enabled.
2. If the plugin is uninstalled.
3. If the plugin is disabled.
4. If the specific module is disabled.

**Notes**

Each method is only called once at each logical enablement/disablement event. Please note that the module class's constructor is *not* a reliable place to put initialisation code either, as the classes are often constructed or destructed more often than they are disabled/enabled. However, once enabled, the same class will remain in memory until it is disabled.

**Known Issues**

**Supported Module Types**

Not all module types have been tested, but the following have the following status:

<table>
<thead>
<tr>
<th>Module Type</th>
<th>Confluence Version</th>
<th>Working</th>
</tr>
</thead>
<tbody>
<tr>
<td>Macro Plugins</td>
<td>2.3.3</td>
<td>✓</td>
</tr>
<tr>
<td>Component Plugins</td>
<td>2.3.3</td>
<td>✓</td>
</tr>
<tr>
<td>Event Listener Plugins</td>
<td>2.3.3</td>
<td>✓</td>
</tr>
<tr>
<td>Lifecycle Plugins</td>
<td>2.3.3</td>
<td>✓</td>
</tr>
</tbody>
</table>

**OSGi Plugin Differences**

The component module type for OSGi (version 2) plugins doesn't support the StateAware interface, as they are implemented differently than non-OSGi (version 1) plugins. To achieve the same effect, you can use the two Spring lifecycle interfaces: InitializingBean and DisposableBean. The init() and destroy() methods on these interfaces will be called when the module is enabled or disabled, exactly like StateAware.

Making this change to a component in an existing plugin will be backwards compatible. That is, a component module in a legacy plugin which implements InitializingBean will have its init() method called when it is enabled, exactly the same as such a component in an OSGi plugin.

For more information about the component module type in OSGi plugins, see Component Plugin Module.

**Confluence Plugin Tutorials**

Below are some useful tutorials on how to write specific Confluence plugins.

- Writing a Macro Plugin
- Userinfo Plugin Tutorial

**Userinfo Plugin Tutorial**
Introduction

This tutorial is being written during the course of the development of a Confluence plugin. It is a demonstration of a number of techniques and tips useful to plugin development, and also of how all the various types of Confluence plugin modules can be combined to add new features to the Confluence application.

The plugin being developed during the course of this tutorial is not just a toy or a random idea that was thought up to write a guide around, it's actually something that we intend to make use of on the Atlassian extranet, fulfilling a real requirement of our business.

I'm hoping to add new chapters to the tutorial each week until it development of the plugin is complete.

Requirements

In order to get the most out of this tutorial, you should have:

1. Confluence 2.2 (the plugin makes use of features that were not available in Confluence 2.1 or earlier)
2. A suitable plugin development environment.

The Plugin

On the Atlassian extranet, which is obviously powered by Confluence, we keep a staff directory. This directory is really just a single Confluence page with a section for each staff member. Here's mine:

![Charles Miller](image)

<table>
<thead>
<tr>
<th>Role:</th>
<th>Lead Confluence Developer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Email:</td>
<td><a href="mailto:charles@atlassian.com">charles@atlassian.com</a></td>
</tr>
<tr>
<td>Personal Space:</td>
<td>Home</td>
</tr>
<tr>
<td>Extension:</td>
<td>13</td>
</tr>
<tr>
<td>Mobile:</td>
<td>0414 366 511</td>
</tr>
<tr>
<td>AIM:</td>
<td>carfishy</td>
</tr>
<tr>
<td>MSN Messenger:</td>
<td><a href="mailto:cmiller@pastiche.org">cmiller@pastiche.org</a></td>
</tr>
<tr>
<td>Yahoo:</td>
<td>carfishie</td>
</tr>
<tr>
<td>ICQ:</td>
<td>1939355</td>
</tr>
<tr>
<td>Skype:</td>
<td></td>
</tr>
</tbody>
</table>

When we started the page, there were only about twenty people in the company. Now we've grown over fifty, it has started to become unwieldy, and with each new hire it gets a little harder to maintain. Thus, the aims of the userinfo plugin are:

- Allow users to maintain their own contact details
- Provide a way to display contact information in wiki pages

Once that's done, we could add more features like:

- A searchable / categorisable staff directory
- vCard export of contact information
- iCal export of staff birthdays

(How many of these we get done really depends on how much time I have to spare 😊)

UPT 1 - Getting Started

Set up the Plugin Source Directory

First things first, I'm going to need somewhere to put all my source code.

The How to Build an Atlassian Plugin contains a template directory that you can rename to use for your own plugin. Having a standard directory structure is useful, because it allows you to use maven (or the ant tasks packaged in the plugins directory of your Confluence installation) to build your plugin jar. If you use a different directory structure, you'll have to build the plugin yourself.

You'll have to think of a name for your plugin. There are probably better names than userinfo, but I started this late on a Thursday afternoon. Also, you'll need a package name for your Java code. The Java standard for package names is to reverse your company's domain-name, which is exactly what I've done here:

```
I'm going to be doing all my development for this tutorial in the plugins directory of a copy of Confluence 2.2.5 that I downloaded from the Atlassian website
```

**The Unreliable Narrator**

In fact, I'll be doing all of my development in the same development environment I use to develop Confluence itself. I will then be copying it into the aforementioned plugins directory and taking screenshots, and pretending that's how I developed it in the first place.

In cooking shows, this would be called "...and here's one I prepared earlier."

Make an Empty `atlassian-plugin.xml` file.

You'll need to choose a unique plugin key. I can use the `confluence.extra` prefix for my plugin keys because I work at Atlassian. You should make your plugin key the same as the Java package name you chose earlier. You should also fill in the plugin metadata.

```
<atlassian-plugin name="User Information" key='confluence.extra.userinfo'>
  <plugin-info>
    <description>Allows users to store personal data/contact details about themselves</description>
    <vendor name="Atlassian Software Systems" url="http://www.atlassian.com"/>
    <version>1.0</version>
  </plugin-info>
</atlassian-plugin>
```

Once again, there's a template file in the Plugin Development Kit.

Compile and Upload

The plugin can now be built and installed into Confluence. I have no idea why you'd want to do it, but it's sort of necessary to come away from each step in a tutorial with some tangible evidence you've accomplished something. So here's what my new plugin looks like when I upload it into Confluence's plugin manager:
That's it. A plugin with no plugin modules. Next, we write some code!

Downloads

- The source for the empty plugin: userinfo-src-1.tgz
- The compiled empty plugin jar: plugins-userinfo-1.jar

**UPT 2 - Getting the Data**

Planning Ahead

The initial requirements for the userinfo plugin are that I need to:

1. Gather contact data from users, somehow.
2. Display it, somehow.

In this part of the tutorial, I'm going to cover the first step. But in order to do so, I need to decide how I'm going to gather this information.

The traditional wiki way to do this would be through "magic markup". We would define some special Confluence markup (in Confluence that would be a [macro](https://confluence.org/macros)) that users could insert into a page to set their contact information, and have the macro save that somewhere for later retrieval. This approach makes the programmatic interface very simple (you're only ever writing macros), but it doesn't make life particularly easy for users who have to remember, or continually look up, some obscure wiki syntax.

**Metadata Plugin**

The [Metadata Plugin](https://confluence.org/plugins) is an excellent Confluence plugin that does just this. It allows arbitrary metadata to be added to any page through a macro, and then allows you to collate, tabulate and aggregate that data in some pretty cool ways. If we wanted to go the "magic markup" route, I could just stop the tutorial now and say "use the Metadata Plugin instead".

The Metadata Plugin was written by the [Pantero Corporation](https://confluence.org/pantero), and won an honourable mention in our first ever plugin development competition.

Confluence has powerful plugin module types that allow you to modify not only the content of wiki pages, but the functionality of the Confluence application itself. It's those modules that we will be using to gather our users' contact information:

1. XWork-WebWork Plugins to provide the web form
2. Web UI Plugins to add links to the form into the Confluence UI

In this second part of the tutorial, we will concentrate on using an XWork plugin to display a form to the user, and store and retrieve the information they submit.

Writing the Code

- **UPT 2.1 - The UserInfo Bean**
- **UPT 2.2 - The XWork Action Class**
- **UPT 2.3 - The Velocity Template**
- **UPT 2.4 - Defining the XWork Plugin Module**

The End Result

Compiling and uploading the plugin I've written so far gives me the ability to set and edit my user information:
It's a bit ugly, though:

- I have to navigate to the edit URL myself – /users/userinfo/edituserinfo.action – there's no link from the Confluence UI.
- The page doesn't look like it's integrated into Confluence very well. It doesn't fit in to the right navigational structure.

I'll fix those problems in the part three of the tutorial.

Downloads

2. The compiled plugin jar for this tutorial: plugins-userinfo-2.jar

UPT 2.1 - The UserInfo Bean

The first thing I need is an object to store the user information in. I already know what information I need to store: I'm replicating the contents of our existing staff directory. In Ruby, I'd write something like this:

```ruby
class UserInfo
  attr_accessor :position, :office, :extension, :mobile_phone, :other_phone,
end
```

However, Confluence plugins are written in Java. I've got to write this instead:

```java
package com.atlassian.confluence.extra.userinfo;
import java.io.Serializable;
```
/**
 * Dumb serializable bean so we can fit all the user info in a single property
 */
public class UserInformation implements Serializable {
    private String position;
    private String office;
    private String extension;
    private String mobilePhone;
    private String otherPhone;
    private String aimId;
    private String msnId;
    private String yahooId;
    private String jabberId;
    private String icqId;
    private String skypeId;

    public String getPosition() {
        return position;
    }

    public void setPosition(String position) {
        this.position = position;
    }

    public String getOffice() {
        return office;
    }

    public void setOffice(String office) {
        this.office = office;
    }

    public String getExtension() {
        return extension;
    }

    public void setExtension(String extension) {
        this.extension = extension;
    }

    public String getMobilePhone() {
        return mobilePhone;
    }

    public void setMobilePhone(String mobilePhone) {
        this.mobilePhone = mobilePhone;
    }

    public String getOtherPhone() {
        return otherPhone;
    }

    public void setOtherPhone(String otherPhone) {
        this.otherPhone = otherPhone;
    }

    public String getAimId() {
        return aimId;
    }

    public void setAimId(String aimId) {
        this.aimId = aimId;
    }

    public String getMsnId() {
        return msnId;
    }

    public void setMsnId(String msnId) {
        this.msnId = msnId;
    }

    public String getYahooId()
Luckily, 90% of the typing above can be done for me by any decent Java IDE.

The most important part of the code above is that the object is Serializable. This is what makes it possible to store and retrieve the object later.

**UPT 2.2 - The XWork Action Class**

The Skeleton XWork Action

Confluence uses WebWork 2 as its web framework, which in turn uses a command framework called XWork. XWork plugins allow you to add new commands to Confluence's web framework, which allows you to add pretty much anything to the Confluence web application. For the userinfo plugin, I'm going to add a form page into which users can input their contact details.

I need an action class. It needs to extend ConfluenceActionSupport, a base class that contains the minimum functionality necessary for an action to play well with Confluence.

The Action will also need an instance of the UserInformation object that I defined earlier. I will expose that property with a standard Java getter method, which will make it available when we write our form in the next step.

```java
package com.atlassian.confluence.extra.userinfo;
import com.atlassian.confluence.core.ConfluenceActionSupport;
public class EditUserInfoAction extends ConfluenceActionSupport {
    private UserInformation userInfo = new UserInformation();
    public UserInformation getUserInfo() {
        return userInfo;
    }
}
```

Introducing XStream and the ContentPropertyManager

XStream is a library for serializing Java objects to and from XML. The ContentPropertyManager is a Confluence component that allows you to associate arbitrary properties with any Confluence content object. Every Confluence user has a Content object associated with them, their PersonalInformation.

The combination of these three things is how I am going to store a user's contact details, by adding the following to the EditUserInfoAction.
In the above code, we are relying on the fact that Spring, Confluence’s component manager, will autowire XWork actions (or any other plugin module). If you need a reference to any Confluence component (like the xStream service, ContentPropertyManager or PersonalInformationManager), all you need to do is provide the appropriate setter method, and the component will be provided to the action before it is executed.

From there we can write the code to write and read our contact details from the appropriate content property.

XWork Action Methods

Our XWork action class is going to handle two situations.

1. The user is viewing the ‘edit my contact information’ form. The form should be pre-filled with their contact information
2. The user is submitting changes to the form.

By convention, these two cases are dealt with using the action’s doDefault and execute methods, respectively. For the doDefault method, all I have to do is make sure that the userInfo property contains the user’s up-to-date contact details. getRemoteUser is a method on ConfluenceActionSupport that returns the currently logged-in user.

```java
public String doDefault() throws Exception
{
    userInfo = getUserInformation(getRemoteUser().getName());
    return super.doDefault();
}
```

For the execute method, I have to write the userInfo property back out. For now, let’s assume that XWork is magic, and that by the time execute() is invoked, userInfo has been populated with the values submitted by the user.
One thing I'm not doing here is validating the form input. This is mostly because the data I am collecting requires more effort to validate than it is worth. I don't really care too much if someone types an invalid email address, they can just go fix it themselves.

If you wanted to add validation to the action, you could do so by implementing a validate() method, as described in the XWork custom validation documentation.

UPT 2.3 - The Velocity Template

Having written the model and the controller, it's now time to work on the view. Confluence views are written in Velocity.

Our velocity template needs to draw a form. It needs to populate that form with the UserInformation object we loaded during the doDefault method of the EditUserInfoAction, and submit it back to the action for saving.

I put the velocity file in src/etc/templates/extra/userinfo/edituserinfo.vm.

```html
<html>
<head>
<title>Edit Contact Details</title>
</head>
<body>
<div class="thickPadded">
<form name="edituserinfo.form" method="POST" action="doedituserinfo.action">
<table class="greyBox" width="450" cellpadding="2" cellspacing="4">

  #tag( TextField "label='Position'" "name='userInfo.position'" "size='50'" )
  #tag( TextField "label='Office'" "name='userInfo.office'" "size='50'" )
  #tag( TextField "label='Extension'" "name='userInfo.extension'" "size='4'" )

  <tr><td colspan="2" &nbsp;</td></tr>
  #tag( TextField "label='Mobile Phone'" "name='userInfo.mobilePhone'" "size='20'" )
  #tag( TextField "label='Other Phone'" "name='userInfo.otherPhone'" "size='20'" )
  #tag( TextField "label='AOL Instant Messenger'" "name='userInfo.aimId'" "size='30'" )
  #tag( TextField "label='MSN Messenger'" "name='userInfo.msnId'" "size='30'" )
  #tag( TextField "label='Yahoo!'" "name='userInfo.yahooId'" "size='30'" )
  #tag( TextField "label='Jabber'" "name='userInfo.jabberId'" "size='30'" )
  #tag( TextField "label='ICQ'" "name='userInfo.icqId'" "size='10'" )
  #tag( TextField "label='Skype'" "name='userInfo.skypeId'" "size='30'" )

  <tr><td colspan="2" align="center">
  &nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&n
  
  </td></tr>
</table>
</form>
</div>
</body>
</html>
```

Here I'm taking advantage of WebWork Velocity tags to draw the form elements. The velocity tags take care of making the form elements part of the surrounding table, formatting them, filling them with their associated data, and if necessarily associating them with validation errors.

Note that we've called each form userInfo.propertyName. This means that when we submit the form, XWork will call getUserInfo().setPropertyName(value) for each property, thus populating our UserInformation bean before it is saved in the execute() method.

Note also that this HTML is lacking anything to define the Confluence look and feel. SiteMesh will take care of filling in the surrounding detail.

UPT 2.4 - Defining the XWork Plugin Module
Now I've written my action class, I'll need to define a plugin module that adds my class to Confluence's XWork configuration. This is done by adding this section to my `atlassian-plugin.xml` file.

```xml
<xwork name="userinfoactions" key="userinfoactions">
  <description>Actions for manipulating a user's personal information.</description>
  <package name="userinfo" extends="default" namespace="/users/userinfo">
    <default-interceptor-ref name="defaultStack" />
    <action name="edituserinfoinfo" class="com.atlassian.confluence.extra.userinfo.EditUserInfoAction" method="doDefault">
      <result name="input" type="velocity">/templates/extra/userinfo/edituserinfo.vm</result>
    </action>
    <action name="doedituserinfo" class="com.atlassian.confluence.extra.userinfo.EditUserInfoAction">
      <result name="input" type="velocity">/templates/extra/userinfo/edituserinfo.vm</result>
      <result name="success" type="velocity">/templates/extra/userinfo/edituserinfo.vm</result>
    </action>
  </package>
</xwork>
```

Some notes:
- You can read more about XWork plugin modules here: [XWork-WebWork Plugins]
- The `<package>` section is essentially passed verbatim to XWork as if it was an `xwork.xml` file, so the best place to look for more information is the XWork documentation.
- I've define two actions: one for viewing the form, and the other for submitting it.
- Since I'm not doing any input validation, I'm using the `defaultStack` interceptor chain.

**UPT 3 - Integrating with the Confluence UI**

Making it Look Good

I've written my form for entering my contact information, but it doesn't exactly look like a part of the Confluence UI yet. There's no link to it from the regular navigation, and it's not decorated with all of the the Confluence look and feel.

Writing the Code

- UPT 3.1 - Linking Using Web UI Plugins
- UPT 3.2 - Using Inline Decorators

The End Result

The input page for my details is now decorated to look like a part of the user's profile editing screen, and is linked from just where you'd expect to find it:

Downloads

1. The source code for this tutorial: [*userinfo-src-3.tgz*]
2. The compiled plugin jar for this tutorial: [*plugins-userinfo-3.jar*]

**UPT 3.1 - Linking Using Web UI Plugins**

Web UI Plugins allow plugin authors to insert links to their custom actions or servlets directly into the Confluence UI, at predetermined locations. The implementation is pretty simple: for the most part you don't need any custom code to implement them, you just need to add their definitions to `atlassian-plugin.xml`.

For my userinfo plugin, I am going to create a link to my custom action in the user's profile, just where they would edit any of their other account details:

```xml
<web-item key="edituserinfoinfo" name="Edit Profile" section="system.profile.edit/yourprofile" weight="20">
  <label key="Contact Details" />
  <link>/users/userinfo/edituserinfo.action</link>
</web-item>
```

Some notes:
- The `section` attribute determines where in the Confluence UI the item will be inserted. The best way to find out which section is correct is to look at Confluence's default web items in WEB-INF/classes/plugins (they're defined in the -sections.xml and -tabs.xml files)
- You can also define icons for your link, but since this section doesn't use icons, we don't bother.
Now the link points to where we want it to, but when you follow the link, you're blown out of the theme's tab layout. This is what we fix by adding a decorator to the form template.

**UPT 3.2 - Using Inline Decorators**

This is the part of the tutorial with the most voodoo, at least so far. It involves changing the `edituserinfo.vm` file so that it will invoke the correct decorator, which in turn will make the plugin look like it is an integrated part of the Confluence UI. While following the instructions in this page will give you a general idea of what I'm accomplishing, some of the decisions I make, like which decorator to call and which action class to extend, are only applicable to this particular plugin.

The best way to find out what's right for your plugin, if you're not familiar enough with the Confluence codebase to find out for yourself, is to ask on the developer mailing list. This tutorial should at least give you a good idea what questions you need to ask.

**Inline Decorators**

Confluence makes heavy use of the Sitemesh library to lay out pages. Sitemesh works by decorating content. The main decorator, `main.vmd` is applied to each page automatically. You can see this by looking at the results of part 2 of the tutorial. Despite the fact that `edituserinfo.vm` does not contain any of the code for the search bar, top bar or profile links, they're included on the resulting page.

The decorators that are used to build the tab panels and other themeable parts of the Confluence page are invoked manually as inline decorators. In order to make the plugin a part of the profile tab infrastructure, I modify the vm file like this (The full velocity file is [attached `edituserinfo.vm`], this is just the important bit we're adding):

```velocity
#applyDecorator("root")
#decoratorParam("context" "profile")
#decoratorParam("mode" "edit-profile")
#decoratorParam("helper" $action.helper)
#decoratorParam("infopanel-width" "200px")

<!-- the stuff we want decorated -->
@end
```

- You will always be applying the "root" decorator. The root decorator is a dispatcher which chooses the correct theme decorator to apply, based on the context and mode arguments supplied.
- The `profile` context and `edit-profile` mode tell the root decorator that we are displaying the profile tabs, and that we currently have the `edit` tab selected.
- The `helper` must always be passed as a parameter.
- The `infopanel-width` should also be passed, it doesn't really do anything useful but some pages still need it.

**Modifying the Action**

Each inline decorator makes certain assumptions about the action class that it is a result of. For example, when drawing the HTML for the `profile` context, the decorator assumes the existence of a `getUser()` method on the action. The easiest way to ensure that I have all the right methods for the decorator is to find the abstract class that all of the stock Confluence actions that use that decorator extends. In the case of the profile, this is `com.atlassian.confluence.user.actions.AbstractUserProfileAction`. By modifying my `EditUserInfoAction` so that it extends `AbstractUserProfileAction`, the decorator will be able to render successfully.
Form Token Handling

Overview and Purpose

Confluence 3.0 employs a new token authentication mechanism that is utilised when Confluence actions are performed either through link request or form submission. This provides Confluence with the means to validate the origin and intent of the request, thus adding an additional level of security against cross-site request forgery. While the core Confluence product and its bundled plugins use this token handling mechanism by default, non-bundled plugins or those developed by third parties may not.

This document is intended for Confluence plugin developers. It provides instructions on how these developers can add this token handling mechanism to their own plugins. Developers should pay particular attention to the Timeline section, as unmodified plugins may no longer function correctly after the cut-off date.

This change affects:

- Plugins that provide actions via XWork plugin modules
- Plugins that create links to, or submit forms to existing Confluence actions

Form Tokens

Confluence 3.0 requires that WebWork actions possess tokens, which are then verified when the form is submitted back to the Confluence server.

This is an "opt in" mechanism, whereby actions must declare that they require a token to be present in the request. However, in a future version of Confluence, the security policy will switch to a more stringent "opt out" system, where actions must declare that they do not require a token. At this point, any plugin that accepts form submissions and has not been upgraded to use this token authentication mechanism will cease to function.

Instructions for Plugin Developers

Configuring XWork Actions

There are two mechanisms for providing a Form Token configuration for an XWork action:

<table>
<thead>
<tr>
<th>Configuration Location</th>
<th>Steps Required</th>
</tr>
</thead>
</table>
| In the Action class    | 1. Locate the method that is called by the action execution (by default this method is called `execute()`)
|                        | 2. Add the `@com.atlassian.xwork.RequireSecurityToken` annotation to this method:
|                        |   @ RequireSecurityToken(true) if the method will require a token, or
|                        |   @ RequireSecurityToken(false) if it will not. |
| In `atlassian-plugins.xml` | 1. Locate the action definition (the `<action>` element in your `<xwork>` plugin module) |
|                        | 2. Add `<param name="RequireSecurityToken">true</param>` if you wish the action execution to require a token, or change its value to `false` if it does not. |

We recommend developers use the `atlassian-plugins.xml` approach, as it will allow their plugins to be backwards-compatible with older versions of Confluence.

Providing the token in HTML Forms

The Velocity macro `#form_xsrfToken()` will insert the following into your form:

```html
<input type="hidden" name="atl_token" value="[the user's token]">
```

Providing the token in HTML links

The Velocity macro `#url_xsrfToken()` expands to:
So you can do the following

```html
&lt;a href=&quot;myaction.action?activate=true&amp;url_xsrfToken()&quot;\&gt;Activate\&lt;/a&gt;
```

**Providing the token in AJAX calls**

The Atlassian Javascript Library (AJS) contains a method that will add the security token to an AJAX callback. In order to make this method available, you should place the following call in your Velocity template:

```javascript
#requireResource("confluence.web.resources:safe-ajax")
```

This library provides wrappers around jQuery AJAX functions that will include the form token in the AJAX submission. If you are not using the jQuery AJAX functions, you should first update your code to use them directly, then to use the safe version. The following functions are provided:

- AJS.safe.ajax()
- AJS.safe.get()
- AJS.safe.post()
- AJS.safe.getScript()
- AJS.safe.getJSON()

**Accessing the token programatically**

To get hold of the current user's token, you will need to make the following call:

```java
new com.atlassian.xwork.SimpleXsrfTokenGenerator().generateToken(httpServletRequest)
```

For best long-term compatibility, you should retrieve the name of the form parameter to set from the token generator rather than using the literal string "atl_token". For example:

```java
HttpServletRequest req = ServletActionContext.getRequest();
if (req != null) {
    XsrfTokenGenerator tokenGenerator = new SimpleXsrfTokenGenerator();
    myWebRequest.addParameter(tokenGenerator.getXsrfTokenName(),
        tokenGenerator.generateToken(req));
    // or: myRequestUrl.append("&" + tokenGenerator.getXsrfTokenName() + "=" +
        tokenGenerator.generateToken(req));
} else {
    // We are not in a web context. Handle this error cleanly.
}
```

**Scripting**

Scripts that access Confluence remotely may have trouble acquiring or returning a security token, or maintaining an HTTP session with the server. There is a way for scripts to opt out of token checking by providing the following HTTP header in the request:

```http
X-Atlassian-Token: no-check
```

**Timeline**

**Confluence 3.0**

- Confluence 3.0 will ship with the token generation/checking code in "opt out" mode.

**The Future**

- Our plans are to switch Confluence to ship with a more strict "opt out" protection in the future. At this point, plugins that have not been modified to use form tokens may cease to function.
- We will give more information on these plans once the exact timing is finalised and warn of the changes in advance to give developers time to test plugin compatibility.
RELATED TOPICS

For more information, refer to the Open Web Application Security Project page.

Internationalising Confluence Plugins

Text in Confluence plugins can be internationalised to cater for a variety of locales or languages. To do this, you will need to create a translated copy of the properties file(s) for each plugin and bundle these inside your language pack plugin. Having a properties file in each plugin allows plugin authors to provide internationalised plugins without having to add their i18n keys to Confluence’s core source.

Confluence comes bundled with a few plugins that are stored in a file called `atlassian-bundled-plugins.zip`. The basic process for translating a plugin is:

1. Extract this zip to a directory
2. Extract the plugin JAR
3. Locate the properties file which contains i18n keys (examples are below)
4. Copy this file to the same location in your plugin. For example, if it is in path/to/file.properties, it needs to be in the same place in your language pack JAR with a locale extension: `path/to/file_jp_JP.properties`
5. Repeat this for all plugins that can be internationalised

Below is a list of bundled plugins that can be internationalised and the properties file you will need to translate (correct as of Confluence 2.7):

<table>
<thead>
<tr>
<th>Plugin Name</th>
<th>Filename</th>
<th>18N Resources</th>
</tr>
</thead>
<tbody>
<tr>
<td>Usage Statistics Plugin</td>
<td>usage-tracking-plugin-&lt;version&gt;.jar</td>
<td>resources/stats/usage.properties</td>
</tr>
<tr>
<td>Atlassian Plugin Repository</td>
<td>atlassian-plugin-repository-confluence-plugin-&lt;version&gt;.jar</td>
<td>resources/18n/repository-templates.properties</td>
</tr>
<tr>
<td>Clickr Theme</td>
<td>clickr-theme-plugin-&lt;version&gt;.jar</td>
<td>clickr.properties</td>
</tr>
<tr>
<td>Mail Page Plugin</td>
<td>mail-page-plugin-&lt;version&gt;.jar</td>
<td>resources/mailpage.properties</td>
</tr>
<tr>
<td>Social Bookmarking Plugin</td>
<td>socialbookmarking-&lt;version&gt;.jar</td>
<td>com/atlassian/confluence/plugins/socialbookmarking/18n.properties</td>
</tr>
<tr>
<td>WebDAV Plugin</td>
<td>webdav-plugin-&lt;version&gt;.jar</td>
<td>com/atlassian/confluence/extra/webdav/text.properties</td>
</tr>
<tr>
<td>Charting Plugin</td>
<td>chart-plugin-&lt;version&gt;.jar</td>
<td>chart.properties</td>
</tr>
<tr>
<td>TinyMCE (Rich Text) Editor</td>
<td>atlassian-tinymce-plugin-&lt;version&gt;.jar</td>
<td>com/atlassian/confluence/extra/tinymceplugin/tinymce.properties</td>
</tr>
</tbody>
</table>

Below are the system plugins (found in `confluence/WEB-INF/lib/`) that can be internationalised and the properties file you will need to translate:

<table>
<thead>
<tr>
<th>Plugin Name</th>
<th>Filename</th>
<th>18N Resources</th>
</tr>
</thead>
<tbody>
<tr>
<td>Information Plugin</td>
<td>confluence-information-plugin-&lt;version&gt;.jar</td>
<td>information.properties</td>
</tr>
<tr>
<td>Layout Plugin</td>
<td>confluence-layout-plugin-&lt;version&gt;.jar</td>
<td>layout.properties</td>
</tr>
<tr>
<td>Livesearch Plugin</td>
<td>confluence-livesearch-plugin-&lt;version&gt;.jar</td>
<td>livesearch.properties</td>
</tr>
<tr>
<td>Dynamic Tasklist Plugin</td>
<td>confluence-dynamictasklist-plugin-&lt;version&gt;.jar</td>
<td>dynamictasklist.properties</td>
</tr>
</tbody>
</table>

Remote API Specification
Introduction

Confluence provides remote APIs as both XML-RPC and SOAP. This document refers to the XML-RPC specification, see SOAP details below. XML-RPC and SOAP are both remote choices, as they have bindings for almost every language making them very portable.

Which should I use?

- SOAP is generally more useful from a strongly typed language (like Java or C#) but these require more setup.
- XML-RPC is easier to use from a scripting language (like Perl, Python, AppleScript etc) and hence is often quicker to use.

⚠️ Looking for the JIRA remote APIs? They are here.

XML-RPC Information

Some borrowed from the (VPWik specification):

- The URL for XML-RPC requests is http://<<confluence-install>>/rpc/xmlrpc.
- All XML-RPC methods must be prefixed by `confluence. - to indicate this is version 1 of the API. We might introduce another version in the future. For example to call the `getPage` method, the method name is `confluence.getPage`.
- All keys in structs are case sensitive.
- All strings are decoded according to standard XML document encoding rules. Due to a bug in Confluence versions prior to 2.8, strings sent via XML-RPC are decoded using the JVM platform default encoding (CONF-10213) instead of the XML encoding.
- Confluence uses 64 bit long values for things like object IDs, but XML-RPC's largest supported numeric type is int32. As such, all IDs and other long values must be converted to Strings when passed through XML-RPC API.
- Anywhere you see the word Vector, you can interchange it with "Array" or "List" depending on what language you prefer. This is the array data type as defined in the XML-RPC spec.
- Anywhere you see the word Hashtable, you can interchange it with "Struct" or "Dictionary" or "Map" depending on what language you prefer. This is the struct data type as defined in the XML-RPC spec.
- The default session lifetime is 30 minutes, but that can be controlled by the deployer from the applicationContext.xml file. This can be found in the /confluence/WEB-INF/lib/confluence-x.jar file.

SOAP Information

The SOAP API follows the same methods as below, except with typed objects (as SOAP allows for).

To find out more about the SOAP API, simply point your SOAP ‘stub generator’ at the WSDL file, located at

1139

For reference, the confluence.atlassian.com WSDL file is here.

The Confluence Command Line Interface is a good place to get a functioning client.

### Remote Methods

#### Authentication Methods

- `String login(String username, String password)` - log in a user. Returns a String authentication token to be passed as authentication to all other remote calls. It's not bulletproof auth, but it will do for now. Must be called before any other method in a 'remote conversation'. From 1.3 onwards, you can supply an empty string as the token to be treated as being the anonymous user.
- `boolean logout(String token)` - remove this token from the list of logged in tokens. Returns true if the user was logged out, false if they were not logged in in the first place.

#### Administration

- `String exportSite(String token, boolean exportAttachments)` - exports a Confluence instance and returns a String holding the URL for the download. The boolean argument indicates whether or not attachments ought to be included in the export.
- `ClusterInformation getClusterInformation(String token)` - returns information about the cluster this node is part of.
- `Vector getClusterNodeStatuses(String token)` - returns a Vector of NodeStatus objects containing information about each node in the cluster.
- `boolean isPluginEnabled(String token, String pluginKey)` - returns true if the plugin is installed and enabled, otherwise false.
- `boolean installPlugin(String token, String pluginFileName, byte[] pluginData)` - installs a plugin in Confluence. Returns false if the file is not a JAR or XML file. Throws an exception if the installation fails for another reason.

#### General

- `ServerInfo getServerInfo(String token)` - retrieve some basic information about the server being connected to. Useful for clients that need to turn certain features on or off depending on the version of the server. (Since 1.0.3)

#### Spaces

#### Retrieval

- `Vector getSpaces(String token)` - returns all the Spaces that the current user can see.
- `Space getSpace(String token, String spaceKey)` - returns a single Space. If the spaceKey does not exist: earlier versions of Confluence will throw an Exception. Later versions (3.0+) will return a null object.
- `string importSpace(String token, byte[] zippedImportData)` - import a space into Confluence. Note that this uses a lot of memory - about 4 times the size of the upload. The data provided should be a zipped XML backup, the same as exported by Confluence.

#### Management

- `Space addSpace(String token, Space space)` - create a new space, passing in name, key and description.
- `Boolean removeSpace(String token, String spaceKey)` - remove a space completely.
- `Space addPersonalSpace(String token, Space personalSpace, String userName)` - add a new space as a personal space.
- `boolean convertToPersonalSpace(String token, String userName, String spaceKey, String newSpaceName, boolean updateLinks)` - convert an existing space to a personal space.
- `Space storeSpace(String token, Space space)` - create a new space if passing in a name, key and description or update the properties of an existing space. Only name, homepage or space group can be changed.
- `boolean importSpace(String token, byte[] zippedImportData)` - import a space into Confluence. Note that this uses a lot of memory - about 4 times the size of the upload. The data provided should be a zipped XML backup, the same as exported by Confluence.

#### Pages

#### Retrieval

- `Vector getPages(String token, String spaceKey)` - returns all the PageSummaries in the space. Doesn't include pages which are in the Trash. Equivalent to calling `Space.getCurrentPages()`.
- `Page getPage(String token, String pageId)` - returns a single Page.
- `Page getPage(String token, String spaceKey, String pageTitle)` - returns a single Page.
- `Vector getPageHistory(String token, String pageId)` - returns all the PageHistorySummaries - useful for looking up the previous versions of a page, and who changed them.

#### Permissions

- `Vector getContentPermissionSets(String token, String contentId)` - returns all the page level permissions for this page as `ContentPermissionSets`
- `Hashtable getContentPermissionSet(String token, String contentId, String permissionType)` - returns the set of permissions on a page as a map of type to a list of `ContentPermission`, for the type of permission which is either 'View' or 'Edit'.
- `Boolean setContentPermissions(String token, String contentId, String permissionType, Vector permissions)` - sets the page-level permissions for a particular permission type (either 'View' or 'Edit') to the provided vector of `ContentPermissions`. If an empty list of permissions are passed, all page permissions for the given type are removed. If the existing list of permissions are passed, this method does nothing.
Dependencies

- Vector getAttachments(String token, String pageld) - returns all the Attachments for this page (useful to point users to download them with the full file download URL returned).
- Vector getAncestors(String token, String pageld) - returns all the ancestors (as PageSummaries) of this page (parent, parent's parent etc).
- Vector getChildren(String token, String pageld) - returns all the direct children (as PageSummaries) of this page.
- Vector getDescendants(String token, String pageld) - returns all the descendents (as PageSummaries) of this page (children, children's children etc).
- Vector getComments(String token, String pageld) - returns all the comments for this page.
- Comment COMMENT getComment(String token, String commentId) - returns an individual comment.
- Comment COMMENT addComment(String token, Comment comment) - adds a comment to the page.
- boolean removeComment(String token, String commentId) - removes a comment from the page.

Management

- Page storePage(String token, Page page) - adds or updates a page. For adding, the Page given as an argument should have space, title and content fields at a minimum. For updating, the Page given should have id, space, title, content and version fields at a minimum. The parentId field is always optional. All other fields will be ignored. Note: the return value can be null, if an error that did not throw an exception occurred.
- String renderContent(String token, String spaceKey, String pageId, String content) - returns the HTML rendered content for this page. If 'content' is provided, then that is rendered as if it were the body of the page (useful for a 'preview page' function). If it's not provided, then the existing content of the page is used instead (ie useful for 'view page' function).
- String renderContent(String token, String spaceKey, String pageld, String content, Hashtable parameters) - Like the above renderContent(), but you can supply an optional hash (map, dictionary, etc) containing additional instructions for the renderer. Currently, only one such parameter is supported:
  - "style = clean" Setting the "style" parameter to "clean" will cause the page to be rendered as just a single block of HTML within a div, without the HTML preamble and stylesheet that would otherwise be added.
- void removePage(String token, String pageId) - removes a page
- void movePage(String sourcePageId, String targetPageId, String position) - moves a page's position in the hierarchy.
  - sourcePageId - the id of the page to be moved.
  - targetPageId - the id of the page that is relative to the sourcePageId page being moved.
  - position - "above", "below", or "append". (Note that the terms 'above' and 'below' refer to the relative vertical position of the pages in the page tree.)
- void movePageToTopLevel(String pageId, String targetSpaceKey) - moves a page to the top level of the target space. This corresponds to PageManager - movePageToTopLevel.

Position Keys for Moving a Page

<table>
<thead>
<tr>
<th>Position Key</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>above</td>
<td>source and target become/remain sibling pages and the source is moved above the target in the page tree.</td>
</tr>
<tr>
<td>below</td>
<td>source and target become/remain sibling pages and the source is moved below the target in the page tree.</td>
</tr>
<tr>
<td>append</td>
<td>source becomes a child of the target.</td>
</tr>
</tbody>
</table>

Attachments - new in version 2.0

Retrieval

- Attachment getAttachment(String token, String pageld, String fileName, String versionNumber) - get information about an attachment.
- byte[] getAttachmentData(String token, String pageld, String fileName, String versionNumber) - get the contents of an attachment.

To retrieve information or content from the current version of an attachment, use a 'versionNumber' of "0".

Management

- Attachment addAttachment(String token, long contentId, Attachment attachment, byte[] attachmentData) - add a new attachment to a content entity object. Note that this uses a lot of memory - about 4 times the size of the attachment. The 'long contentId' is actually a String pageld for XML-RPC.
- boolean removeAttachment(String token, String contentId, String fileName) - remove an attachment from a content entity object.
- boolean moveAttachment(String token, String originalContentId, String originalName, String newContentEntityId, String newName) - move an attachment to a different content entity object and/or give it a new name.

Blog Entries

- Vector getBlogEntries(String token, String spaceKey) - returns all the BlogEntrySummaries in the space.
- BlogEntry getBlogEntry(String token, String pageld) - returns a single BlogEntry.
- BlogEntry storeBlogEntry(String token, BlogEntry entry) - add or update a blog entry. For adding, the BlogEntry given as an argument should have space, title and content fields at a minimum. For updating, the BlogEntry given should have id, space, title, content and version fields at a minimum. All other fields will be ignored.
- BlogEntry getBlogEntryByDayAndTitle(String token, String spaceKey, int dayOfMonth, String postTitle) - Retrieves a blog post in the Space with the given spaceKey, with the title 'postTitle' and posted on the day 'dayOfMonth'.

1141
Search

- Vector search(String token, String query, int maxResults) - return a list of SearchResults which match a given search query (including pages and other content types). This is the same as a performing a parameterised search (see below) with an empty parameter map.
- Vector search(String token, String query, Map parameters, int maxResults) - (since 1.3) like the previous search, but you can optionally limit your search by adding parameters to the parameter map. If you do not include a parameter, the default is used instead.

Parameters for Limiting Search Results

<table>
<thead>
<tr>
<th>key</th>
<th>description</th>
<th>values</th>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>spaceKey</td>
<td>search a single space</td>
<td>(any valid space key)</td>
<td>Search all spaces</td>
</tr>
<tr>
<td>type</td>
<td>Limit the content types of the items to be returned in the search results.</td>
<td>page blogpost mail comment attachment spacedescription personalinformation</td>
<td>Search all types</td>
</tr>
<tr>
<td>modified</td>
<td>Search recently modified content</td>
<td>TODAY YESTERDAY LASTWEEK LASTMONTH</td>
<td>No limit</td>
</tr>
<tr>
<td>contributor</td>
<td>The original creator or any editor of Confluence content. For mail, this is the person who imported the mail, not the person who sent the email message.</td>
<td>Username of a Confluence user.</td>
<td>Results are not filtered by contributor</td>
</tr>
</tbody>
</table>

Security

- Vector getPermissions(String token, String spaceKey) - Returns a Vector of Strings representing the permissions the current user has for this space (a list of "view", "modify", "comment" and / or "admin").
- Vector getPermissionsForUser(String token, String spaceKey, String userName) - Returns a Vector of Strings representing the permissions the given user has for this space. (since 2.1.4)
- Vector getPagePermissions(String token, String pageId) - Returns a Vector representing the permissions set on the given page.
- Vector getSpaceLevelPermissions(String token) - returns all of the space level permissions which may be granted. This is a list of possible permissions to use with addPermissionToSpace, below, not a list of current permissions on a Space.
  - boolean addPermissionToSpace(String token, String permission, String remoteEntityName, String spaceKey) - Give the entity named remoteEntityName (either a group or a user) the permission permission on the space with the key spaceKey.
  - boolean removePermissionFromSpace(String token, String permission, String remoteEntityName, String spaceKey) - Remove the permission permission from the entity named remoteEntityName (either a group or a user) the permissions permissions on the space with the key spaceKey.

- boolean addAnonymousPermissionToSpace(String token, String permission, String spaceKey) - Give anonymous users the permission permission on the space with the key spaceKey. (since 2.0)
- boolean addAnonymousPermissionsToSpace(String token, Vector permissions, String spaceKey) - Give anonymous users the permissions permissions on the space with the key spaceKey. (since 2.0)
- boolean removeAnonymousPermissionFromSpace(String token, String permission, String spaceKey) - Remove the permission permission from anonymous users on the space with the key spaceKey. (since 2.0)

- boolean removeAllPermissionsForGroup(String token, String groupname) - Remove all the global and space level permissions for groupname.

Space permissions

Names are as shown in Space Admin > Permissions. Values can be passed to security remote API methods above which take a space permission parameter.

<table>
<thead>
<tr>
<th>Permission name</th>
<th>String value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>View</td>
<td>VIEWSPACE</td>
<td>View all content in the space</td>

<td>REMOVEPAGE</td>
<td>Remove pages</td>
</tr>
</tbody>
</table>
## User Management

- **User**
  - `getUser(String token, String username)` - get a single user
  - `addUser(String token, User user, String password)` - add a new user with the given password
  - `addGroup(String token, String group)` - add a new group
  - `getGroups(String token)` - gets all groups
  - `hasUser(String token, String username)` - checks if a user exists
  - `getGroup(String token, String groupName)` - checks if a group exists
  - `editUser(String token, RemoteUser remoteUser)` - edits the details of a user
  - `deactivateUser(String token, String username)` - deactivates the specified user
  - `reactivateUser(String token, String username)` - reactivates the specified user
  - `getUserInformation(String token, UserInformation userInfo)` - retrieves user information
  - `changeUserPassword(String token, String username, String newPass)` - changes the specified user's password
  - `addProfilePicture(String token, String userName, String fileName, String mimeType, byte[] pictureData)` - add and set the profile picture for a user.
  - `setUserInformation(String token, UserInformation userInfo)` - updates user information
  - `deactivateUser(String token, String username)` - deactivates the specified user
  - `reactivateUser(String token, String username)` - reactivates the specified user
  - `hasGroup(String token, String groupname)` - checks if a group exists
  - `removeGroup(String token, String groupname, String defaultGroupName)` - remove a group. If `defaultGroupName` is specified, users belonging to `groupname` will be added to `defaultGroupName`.
  - `addUserToGroup(String token, String username, String groupname)` - add a user to a particular group
  - `removeUserFromGroup(String token, String username, String groupName)` - removes a user from a particular group
  - `getUserGroups(String token, String username)` - get a user's current groups
  - `getActiveUsers(String token, String username)` - returns all registered users
  - `getSpacesWithLabel(String token, String labelName)` - returns all spaces that have been labelled with `labelName`.
  - `getSpacesContainingContentWithLabel(String token, String labelName)` - returns all spaces that have content labelled with `labelName`.

- **Space**
  - `getSpaces(String token)` - get all spaces
  - `exportSpace(String token, String spaceKey)` - export space to PDF, HTML or XML

- **Attachment**
  - `addAttachment(String token, String spaceKey, String path, String mimeType)` - adds an attachment to a page or news item
  - `removeAttachment(String token, String spaceKey, String path)` - removes an attachment

- **Mail**
  - `removeMail(String token, String spaceKey)` - remove mail

## Labels

- `getLabelsById(String token, long objectId)` - Returns all `Labels` for the given `ContentEntityObject ID`
- `getMostPopularLabels(String token, int maxCount)` - Returns the most popular `Labels` for the Confluence instance, with a specified maximum number.
- `getMostPopularLabelsInSpace(String token, String spaceKey, int maxCount)` - Returns the most popular `Labels` for the given `spaceKey`, with a specified maximum number of results.
- `getRecentlyUsedLabels(String token, int maxResults)` - Returns the recently used `Labels` for the Confluence instance, with a specified maximum number of results.
- `getRecentlyUsedLabelsInSpace(String token, String spaceKey, int maxResults)` - Returns the recently used `Labels` for the given `spaceKey`, with a specified maximum number of results.
- `getRelatedLabels(String token, String labelName, int maxResults)` - Returns the `Labels` related to the given label name, with a specified maximum number of results.
- `getRelatedLabelsInSpace(String token, String labelName, String spaceKey, int maxResults)` - Returns the `Labels` related to the given label name for the given `spaceKey`, with a specified maximum number of results.
- `getLabelContentById(String token, long labelId)` - Returns the content for a given label ID
- `getLabelContentByObject(String token, String labelName, String namespace, String spaceKey, String owner)` - Retrieves the `Labels` matching the given `labelName`, `namespace`, `spaceKey` or `owner`.
- `getLabelContentByObject(String token, String labelName, String spaceKey)` - Returns the content for a given label name.
- `getLabelByAttachment(String token, String labelId, long objectID)` - Returns the label content for a given label ID
  - `getLabelByAttachment(String token, String labelId, long objectID)` - Returns labels for a particular label ID
  - `getLabelByObject(String token, ContentEntityObject ID)` - Returns labels for a particular label ID
  - `addLabelByAttachment(String token, long labelId, long objectID)` - Adds a label to the given object with the given `LabelObject ID`
  - `addLabelByObject(String token, String labelName, long objectID)` - Adds a label to the object with the given `ContentObject ID`.
  - `addLabelByObjectName(String token, String labelName, String spaceKey)` - Adds a label by name to the object with the given `ContentObject ID`.
  - `removeLabelByAttachment(String token, long labelId, long objectID)` - Removes the label from the object with the given `LabelObject ID`
  - `removeLabelByObject(String token, String labelName, long objectID)` - Removes the label from the object with the given `ContentObject ID`.
  - `removeLabelByObjectName(String token, String labelName, String spaceKey)` - Removes the label by name from the object with the given `ContentObject ID`.
  - `addLabelByObjectNameToSpace(String token, String labelName, String spaceKey)` - Adds a label to the object with the given `ContentObject ID`.
  - `removeLabelByObjectNameToSpace(String token, String labelName, String spaceKey)` - Removes the label from the object with the given `ContentObject ID`.

## News

- **Edit**
  - `editBlog(String token, String spaceKey)` - edit news items and edit existing ones
  - `editComment(String token, String spaceKey)` - add comments to pages or news in the space

<table>
<thead>
<tr>

</tr>
<tr>
<td>Space - Admin</td>
<td><code>setSpacePermissions(String token, String spaceKey)</code></td>
<td>Administer the space</td>
</tr>
</tbody>
</table>
Data Objects

Most returned structs have a summary and a detailed form:

- The summary form is a primary key (ie space key, page id) and a representative form (ie space name, page title)
- The detailed form will have all of the entity details as might be needed for the client.

Unless otherwise specified, all returned structs are in detailed form.

ServerInfo

<table>
<thead>
<tr>
<th>Key</th>
<th>Type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>majorVersion</td>
<td>int</td>
<td>the major version number of the Confluence instance</td>
</tr>
<tr>
<td>minorVersion</td>
<td>int</td>
<td>the minor version number of the Confluence instance</td>
</tr>
<tr>
<td>patchLevel</td>
<td>int</td>
<td>the patch-level of the Confluence instance</td>
</tr>
<tr>
<td>buildId</td>
<td>String</td>
<td>the build ID of the Confluence instance (usually a number)</td>
</tr>
<tr>
<td>developmentBuild</td>
<td>Boolean</td>
<td>Whether the build is a developer-only release or not</td>
</tr>
<tr>
<td>baseUrl</td>
<td>String</td>
<td>The base URL for the confluence instance</td>
</tr>
</tbody>
</table>

Note: Version 1.0.3 of Confluence would be major-version: 1, minor-version: 0, patch-level: 3. Version 2.0 would have a patch-level of 0, even if it's not visible in the version number.

Script Examples

The Confluence Extension space contains various examples of scripts

Changelog

**Confluence 2.9**

- Search: Removed option 'all' in table of content types and changed the default to 'All'. If you need to search for all types, simply omit the 'type' restriction.
- Search: Added option 'contributor' to the table of filter options.

**2.3**

- Added getClusterInformation and getClusterNodeStatuses.

**2.2**

- Added addPersonalSpace, convertToPersonalSpace and addProfilePicture.

**2.1.4**

- Added getPermissionsForUser.

**2.0**

- Updated getLocks() to getPagePermissions()
- Added addAttachment, getAttachment, getAttachmentData, removeAttachment and moveAttachment methods to allow remote attachment handling. Note that adding large attachments with this API uses a lot of memory during the addAttachment operation.
- Added addAnonymousPermissionToSpace, addAnonymousPermissionsToSpace and removeAnonymousPermissionFromSpace.
- Added the addComment and removeComment methods for comment manipulation.
- Added hasGroup and hasUser methods to determine if a group or user exists.
- Added editUser method.
- Added ability to deactivate and reactivate users.
- Added getActiveUsers method to retrieve a user list.
- Added ability to change the user password.
- Added ability to retrieve and modify user information.
- Added ability to retrieve, add and remove labels.
- Added getBlogEntryByDayAndTitle

**1.4**

- Added new exportSpace and exportSite methods to build exports of an individual space or an entire Confluence instance and return with a URL leading to the download.
- Added new getChildren and getDescendents methods to get the direct children and all descendents of a given page.
- Added new getAncestors method to get the ancestors of a given page.
- Removed the old getLocks as locks are superceded by page level permissions.
- Added new getPagePermissions method to retrieve page level permissions.
- Added new removeUser, removeGroup, removeAllPermissionsForGroup, addUserToGroup and removeUserFromGroup methods.
- Added new addPermissionToSpace method.
- Added new Permission data object.
- Added new getSpaceLevelPermissions method.

**1.3**
• Added new `getPage` method which retrieves a page by space key and page title.
• Added new `removeSpace` method to remove an entire space.
• Added ability to limit search by parameters.
• Allow anonymous access.

1.2

• `renderContent` takes an optional hashtable for rendering hints, the only one supported right now is "style=clean"

1.1

• `getLocks` gives you back a list of any locks that apply to a given page
• added a `locks` field to the various `Page` structs containing a count of any applicable page-level locks
• CRUD methods added for blog-posts

1.0.3

• `getServerInfo` gives you some basic information about the server version CONF1123
• `storePage` now allows you to change the page's name (incoming links are all renamed) CONF-974
• `storePage` now reliably allows you to re-parent pages
• WSDL now respects the server's configured base URL, allowing it to work on proxy-hosted servers CONF-1088

Extending the V2 search API

If none of the bundled `SearchQuery`, `SearchSort`, `SearchFilter` or `ResultFilter` implementations fits your requirements, you can write your own implementation.

Writing your Own SearchQuery

To illustrate how to write your own `SearchQuery`, we will take a look at how the bundled `CreatorQuery` was written.

Implement `SearchQuery`

First of all, you need to implement `SearchQuery`. This is a generic simple Java object representing your custom search.

```java
public class CreatorQuery implements SearchQuery {
    private static final String KEY = "creator";

    private final String creator;

    public CreatorQuery(String creator) {
        this.creator = creator;
    }

    public String getKey() {
        return KEY;
    }

    public String getCreator() {
        return creator;
    }

    public List getParameters() {
        return Collections.singletonList(getCreator());
    }
}
```

Comments:

• Search query objects should be immutable.
They should be constructed with all the required input to complete the query. In this case, we query on the creator username, so this is passed as a constructor parameter.

Input should be exposed via an accessor. This will be used by the mapper, which we'll discuss below.

Your query should have a unique key to identify it. This allows us to configure a mapper to map this type of query — more on this below.

Implement LuceneQueryMapper

The responsibility of the Lucene query mapper is to convert a generic search query POJO (plain old java object) to the actual Lucene search query.

Comments:

- The contract of the LuceneQueryMapper is to return a org.apache.lucene.search.Query given a Confluence v2 search query object.
- We call getCreator() on CreatorQuery and use it to construct the Lucene query.

Add your custom LuceneQueryMapper as a plugin in atlassian-plugins.xml

A new plugin type has been introduced for custom Lucene query mappers using the lucene-query-mapper tag. You should add this to your plugin descriptor and define what v2 search query objects it can handle.

Comments:

- The handles attribute should be set to the unique keys you defined for your custom search query objects (that is, CreatorQuery.KEY in this example).
- If you want to handle multiple query types with your mapper, you can declare this by specifying a <handles>creator</handles> sub tag for each type supported.
- The key attribute is a value to uniquely identify this mapper plugin.

- Remote API Specification

API documentation

Remote API Specification for PDF Export

In Confluence 3.0, we moved the PDF export engine to a Confluence plugin. Therefore, you can no longer use Confluence's built-in remote API to export a space as a PDF. There is a new replacement API that is part of the new PDF export Confluence plugin.

On this page:

- XML-RPC Information
- SOAP Information
  - Methods

XML-RPC Information

- The URL for XML-RPC requests is http://<<confluence-install>>/rpc/xmlrpc.
- All XML-RPC methods must be prefixed by pdfexport.

SOAP Information
To find out more about the SOAP API, simply point your SOAP 'stub generator' at the WSDL file, located at http://<confluence-install>/rpc/soap-axis/pdfexport?wsdl.

For reference, the pdfexport WSDL file is here.

Methods

- `String login(String username, String password) - log in a user. Returns a String authentication token to be passed as authentication to all other remote calls. It's not bulletproof auth, but it will do for now. Must be called before any other method in a 'remote conversation'. From 1.3 onwards, you can supply an empty string as the token to be treated as being the anonymous user.
- `public String exportSpace(String token, String spaceKey) - exports the entire space as a PDF. Returns a url to download the exported PDF. Depending on how you have Confluence set up, this URL may require you to authenticate with Confluence. Note that this will be normal Confluence authentication, not the token based authentication that the web service uses.

Searching using the V2 Search API

The v2 search API provides a fast way of searching content within Confluence. We highly recommend that all plugin authors switch to this API where possible.

To illustrate how to use this API, we have included a simple code snippet for a basic search that:

- searches for all content labelled with `administration` in the space with key `DOC`.
- sorts these results with the latest modified content displayed first.
- limits the number of results to 10.

```java
SearchQuery query = BooleanQuery.composeAndQuery(new LabelQuery("administration"), new InSpaceQuery("DOC"));
SearchSort sort = new ModifiedSort(SearchSort.Order.DESCENDING); // latest modified content first
SearchFilter securityFilter = SiteSearchPermissionsSearchFilter.getInstance();
ResultFilter resultFilter = new SubsetResultFilter(10);
Search search = new Search(query, sort, securityFilter, resultFilter);
SearchResults searchResults;
try {
    searchResults = searchManager.search(search);
} catch (InvalidSearchException e) {
    // discard search and assign empty results
    searchResults = LuceneSearchResults.EMPTY_RESULTS;
}

// iterating over search results
for (SearchResult searchResult : searchResults.getAll()) {
    System.out.println("Title: " + searchResult.getDisplayTitle());
    System.out.println("Content: " + searchResult.getContent());
    System.out.println("SpaceKey: " + searchResult.getSpaceKey());
}

// total number of results found
System.out.println("Total number of results: " + searchResults.getUnfilteredResultsCount());
```

Further comments:

- Please ensure you include `com.atlassian.confluence.search.v2.searchfilter.SiteSearchPermissionsSearchFilter` in your search. This is a bundled filter that will handle permission checking and content filtering automatically for you.
- The number of results returned has been limited with the use of `com.atlassian.confluence.search.v2.filter.SubsetResultFilter`. This class efficiently filters search results during search time.
- The search is executed using `searchManager.search(search)`. This invocation returns search results populated with data from your index.
  - To iterate over the search results returned, you can get a reference to the list of search results with `searchResults.getAll()` or an iterator to this list using `searchResults.iterator()`.
  - Common information about a search result like title, body and space key can be extracted from the search result using `getDisplayTitle()`, `getContent()` and `getSpaceKey()` respectively. For more accessors see the API documentation for `com.atlassian.confluence.search.v2.SearchResult`.
  - This invocation does not go to the database to construct any search results. If you want to get results from the database to be returned by the search, call `searchManager.searchEntities(search)` instead.
- An exception `com.atlassian.confluence.search.v2.InvalidSearchException` is thrown when either:
  - there is an error mapping a v2 search object to the corresponding Lucene search object, or
  - no mapper could be found to map one of the search objects. (The mapper plugin responsible for mapping this search may have been uninstalled.)
- You should simply discard the search if an exception is thrown as described above.
Introduction

Confluence provides remote APIs as both XML-RPC and SOAP. This document refers to the XML-RPC specification, see SOAP details below. XML-RPC and SOAP are both remote choices, as they have bindings for almost every language making them very portable.

Which should I use?

- SOAP is generally more useful from a strongly typed language (like Java or C#) but these require more setup.
- XML-RPC is easier to use from a scripting language (like Perl, Python, AppleScript etc) and hence is often quicker to use.

Looking for the JIRA remote APIs? They are here.

XML-RPC

Read Me First!

XML-RPC notes: (some borrowed from the VPWik specification)

- The URL for XML-RPC requests is http://confluence-install/rpc/xmlrpc.
- All XML-RPC methods must be prefixed by confluence1. to indicate this is version 1 of the API. We might introduce another version in the future. For example to call the getPage method, the method name is confluence1.getPage.
- All keys in structs are case sensitive.
- All strings are passed as UTF-8, and not ASCII per the XML-RPC update on 6/30/2003.
- Confluence uses 64 big long values for things like object IDs, but XML-RPC’s largest supported numeric type is int32. As such, all IDs and other long values must be converted to Strings when passed through XML-RPC API.
- Anywhere you see the word Vector, you can interchange it with “Array” or “List” depending on what language you prefer. This is the array data type as defined in the XML-RPC spec.
- Anywhere you see the word Hashtable, you can interchange it with “Struct” or “Dictionary” or “Map” depending on what language you prefer. This is the struct data type as defined in the XML-RPC spec.
- The default session lifetime is 30 minutes, but that can be controlled by the deployer from the applicationContext.xml file.

SOAP

The SOAP API follows the same methods as below, except with typed objects (as SOAP allows for).

To find out more about the SOAP API, simply point your SOAP ‘stub generator’ at the WSDL file, located at http://<confluence-install>/rpc/soap-axis/confluenceservice-v1?wsdl.

For reference, the confluence.atlassian.com WSDL file is here.

Changelog

2.4

Following methods were added:

- storeSpace
- importSpace
- getSpacesInGroup
- addSpaceGroup
Added new SpaceGroup data object.

2.3

- Added getClusterInformation and getClusterNodeStatuses.

2.2

- Added addPersonalSpace, convertToPersonalSpace and addProfilePicture.

2.1.4

- Added getPermissionsForUser.

2.0

- Updated getLocks() to getPagePermissions()
- Added addAttachment, getAttachment, getAttachmentData, removeAttachment and moveAttachment methods to allow remote attachment handling. Note that adding large attachments with this API uses a lot of memory during the addAttachment operation.
- Added addAnonymousPermissionToSpace, addAnonymousPermissionsToSpace and removeAnonymousPermissionFromSpace.
- Added the addComment and removeComment methods for comment manipulation.
- Added hasGroup and hasUser methods to determine if a group or user exists.
- Added editUser method.
- Added ability to deactivate and reactivate users.
- Added getActiveUsers method to retrieve a user list.
- Added ability to change the user password.
- Added ability to retrieve and modify user information.
- Added ability to retrieve, add and remove labels.
- Added getBlogEntryByDayAndTitle

1.4

- Added new exportSpace and exportSite methods to build exports of an individual space or an entire Confluence instance and return with a URL leading to the download.
- Added new getAncestors and getDescendants methods to get the direct children and all descendents of a given page.
- Removed the old getLocks as locks are superceded by page level permissions.
- Added new getSpaceLevelPermissions method to retrieve page level permissions.
- Added new removeUser, removeGroup, removeAllPermissionsForGroup, addUserToGroup and removeUserFromGroup methods.
- Added new addPermissionToSpace method.
- Added new Permission data object.
- Added new getSpaceLevelPermissions method.

1.3

- Added new getPage method which retrieves a page by space key and page title.
- Added new removeSpace method to remove an entire space.
- Added ability to filter search by parameters.
- Allow anonymous access.

1.2

- renderContent takes an optional hashtable for rendering hints, the only one supported right now is "style=clean"

1.1

- getLocks gives you back a list of any locks that apply to a given page
- added a locks field to the various Page structs containing a count of any applicable page-level locks
- CRUD methods added for blog-posts

1.0.3

- getServerInfo gives you some basic information about the server version CONF1123
- storePage now allows you to change the page's name (incoming links are all renamed) CONF-974
- storePage now reliably allows you to re-parent pages
- WSDL now respects the server's configured base URL, allowing it to work on proxy-hosted servers CONF-1088
Remote Methods

Authentication Methods

- **String login(String username, String password)** - login a user. Returns a String authentication token to be passed as authentication to all other remote calls. It's not bulletproof auth, but it will do for now. Must be called before any other method in a 'remote conversation'. From 1.3 onwards, you can supply an empty string as the token to be treated as being the anonymous user.
- **boolean logout(String token)** - remove this token from the list of logged in tokens. Returns true if the user was logged out, false if they were not logged in in the first place (we don't really need this return, but void seems to kill XML-RPC for me)

Administration

- **String exportSite(String token, boolean exportAttachments)** - exports a Confluence instance and returns a String holding the URL for the download. The boolean argument indicates whether or not attachments ought to be included in the export.
- **ClusterInformation getClusterInformation(String token)** - returns information about the cluster this node is part of.
- **Vector getClusterNodeStatuses(String token)** - returns a Vector of NodeStatus objects containing information about each node in the cluster.

General

- **ServerInfo getServerInfo(String token)** - retrieve some basic information about the server being connected to. Useful for clients that need to turn certain features on or off depending on the version of the server. (Since 1.0.3)

Spaces

Retrieval

- **Vector getSpaces(String token)** - returns all the SpaceSummaries that the current user can see.
- **Vector getSpacesInGroup(String token, String spaceGroupKey)** - returns all the SpaceSummaries from a given group that the current user can see.
- **Space getSpace(String token, String spaceKey)** - returns a single Space.
- **boolean storeSpace(String token, Hashtable Space)** - Allows for modifying space details. Currently you can update the name, homepage and spaceGroup properties of a space. Note that changing the space key and other properties will have no effect.

Management

- **Space addSpace(String token, Space space)** - create a new space, passing in name, key and description.
- **Boolean removeSpace(String token, String spaceKey)** - remove a space completely.
- **Space addPersonalSpace(String token, Space personalSpace, String userName)** - add a new space as a personal space.
- **boolean convertToPersonalSpace(String token, String userName, String spaceKey, String newSpaceName, boolean updateLinks)** - convert an existing space to a personal space.
- **String exportSpace(String token, String spaceKey, String exportType)** - exports a space and returns a String holding the URL for the download. The export type argument indicates whether or not to export in XML, PDF, or HTML format - use "TYPE_XML", "TYPE_PDF", or "TYPE_HTML" respectively. Also, using "all" will select TYPE_XML.
- **boolean importSpace(String token, byte[] importData)** - import a space in a compressed XML format.

SpaceGroups

Retrieval

- **SpaceGroup addSpaceGroup(String token, SpaceGroup spaceGroup)** - create a new space group passing in a SpaceGroup data object
- **Vector spaceGroups(String token)** - returns all the SpaceGroups in Confluence. Requires Confluence Administrator permission.
- **boolean removeSpaceGroup(String token, String spaceGroupKey)** - removes the SpaceGroup with the given key from the system. The contained spaces will not be deleted. Requires Confluence Administrator permission.

Management

Pages

Retrieval

- **Vector getPages(String token, String spaceKey)** - returns all the PageSummaries in the space. Doesn't include pages which are in the Trash. Equivalent to calling Space.getCurrentPages().
- **Page getPage(String token, String pageId)** - returns a single Page
- **Page getPage(String token, String spaceKey, String pageTitle)** - returns a single Page
- **Vector getPageHistory(String token, String spaceKey, String pageId)** - returns all the PageHistorySummaries - useful for looking up the previous versions of a page, and who changed them.
- **Vector getPagePermissions(String token, String pageId)** - returns the page level permissions for this page (since 1.4)

Dependencies

- **Vector getAttachments(String token, String pageId)** - returns all the Attachments for this page (useful to point users to download
them with the full file download URL returned).

- Vector getAncestors(String token, String pageId) - returns all the ancestors (as PageSummaries) of this page (parent, parent's parent etc).
- Vector getChildren(String token, String pageId) - returns all the direct children (as PageSummaries) of this page.
- Vector getDescendents(String token, String pageId) - returns all the descendents (as PageSummaries) of this page (children, children's children etc).
- Vector getComments(String token, String pageId) - returns all the comments for this page.
- Comment getComment(String token, String commentId) - returns an individual comment.
- Comment addComment(String token, Comment comment) - adds a comment to the page.
- boolean removeComment(String token, String commentId) - removes a comment from the page.

Management

- Page storePage(String token, Page page) - add or update a page. For adding, the Page given as an argument should have space, title and content fields at a minimum. For updating, the Page given should have id, space, title, content and version fields at a minimum. The parentid field is always optional. All other fields will be ignored.
- String renderContent(String token, String spaceKey, String pageId, String content) - returns the HTML rendered content for this page. If 'content' is provided, then that is rendered as if it were the body of the page (useful for a 'preview page' function). If it's not provided, then the existing content of the page is used instead (ie useful for 'view page' function).
- String renderContent(String token, String spaceKey, String pageId, String content, Hashtable parameters) - Like the above renderContent(), but you can supply an optional hash (map, dictionary, etc) containing additional instructions for the renderer. Currently, only one such parameter is supported:
  - "style = clean" Setting the "style" parameter to "clean" will cause the page to be rendered as just a single block of HTML within a div, without the HTML preamble and stylesheet that would otherwise be added.
- void removePage(String token, String pageId) - remove a page

Attachments - new in version 2.0

Retrieval

- Attachment getAttachment(String token, String pageId, String fileName, String versionNumber) - get information about an attachment.
- byte[] getAttachmentData(String token, String pageId, String fileName, String versionNumber) - get the contents of an attachment.

Management

- Attachment addAttachment(String token, long contentId, Attachment attachment, byte[] attachmentData) - add a new attachment to a content entity object. Note that this uses a lot of memory - about 4 times the size of the attachment. The 'long contentId' is actually a String pageId for XML-RPC.
- boolean removeAttachment(String token, String contentId, String fileName) - remove an attachment from a content entity object.
- boolean moveAttachment(String token, String originalContentId, String originalName, String newContentEntityId, String newName) - move an attachment to a different content entity object and/or give it a new name.

Blog Entries

- Vector getBlogEntries(String token, String spaceKey) - returns all the BlogEntrySummaries in the space.
- BlogEntry getBlogEntry(String token, String pageId) - returns a single BlogEntry.
- BlogEntry storeBlogEntry(String token, BlogEntry entry) - add or update a blog entry. For adding, the BlogEntry given as an argument should have space, title and content fields at a minimum. For updating, the BlogEntry given should have id, space, title, content and version fields at a minimum. All other fields will be ignored.
- BlogEntry getBlogEntryByDayAndTitle(String token, String spaceKey, int dayOfMonth, String postTitle) - Retrieves a blog post in the Space with the given spaceKey, with the title 'postTitle' and posted on the day 'dayOfMonth'.

Search

- Vector search(String token, String query, int maxResults) - return a list of SearchResults which match a given search query (including pages and other content types). This is the same as a performing a parameterised search (see below) with an empty parameter map.
- Vector search(String token, String query, Map parameters, int maxResults) - (since 1.3) like the previous search, but you can optionally limit your search by adding parameters to the parameter map. If you do not include a parameter, the default is used instead.

Parameters for Limiting Search Results

<table>
<thead>
<tr>
<th>key</th>
<th>description</th>
<th>values</th>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>spaceKey</td>
<td>search a single space</td>
<td>(any valid space key)</td>
<td>Search all spaces</td>
</tr>
<tr>
<td>type</td>
<td>Limit types of search results to return</td>
<td>all page blogpost mail comment attachment spacedescription personalinformation</td>
<td>All except mail</td>
</tr>
</tbody>
</table>
### Security

- **`Vector getPermissions(String token, String spaceKey)`** - Returns a Vector of Strings representing the permissions the current user has for this space (a list of "view", "modify", "comment" and / or "admin").
- **`Vector getPermissionsForUser(String token, String spaceKey, String userName)`** - Returns a Vector of Strings representing the permissions the given user has for this space. (since 2.1.4)
- **`Vector getPerPagePermissions(String token, String pageId)`** - Returns a Vector of Permissions representing the permissions set on the given page.
- **`Vector getSpaceLevelPermissions(String token)`** - returns all of the space level permissions which may be granted. This is a list of possible permissions to use with `addPermissionToSpace`, below, not a list of current permissions on a Space.

- **`boolean addPermissionToSpace(String token, String permission, String remoteEntityName, String spaceKey)`** - Give the entity named `remoteEntityName` (either a group or a user) the permission permission on the space with the key `spaceKey`.
- **`boolean addPermissionsToSpace(String token, Vector permissions, String remoteEntityName, String spaceKey)`** - Give the entity named `remoteEntityName` (either a group or a user) the permissions permissions on the space with the key `spaceKey`.
- **`boolean removePermissionFromSpace(String token, String permission, String remoteEntityName, String spaceKey)`** - Remove the permission permission from the entity named `{remoteEntityName`(either a group or a user) on the space with the key `spaceKey`.

- **`boolean addAnonymousPermissionToSpace(String token, String permission, String spaceKey)`** - Give anonymous users the permission permission on the space with the key `spaceKey`. (since 2.0)

- **`boolean addAnonymousPermissionsToSpace(String token, Vector permissions, String spaceKey)`** - Give anonymous users the permissions permissions on the space with the key `spaceKey`. (since 2.0)

- **`boolean removeAnonymousPermissionFromSpace(String token, String permission, String spaceKey)`** - Remove the anonymous permission from the space with the key `spaceKey`.

### User Management

- **`User getUser(String token, String username)`** - get a single user
- **`void addUser(String token, User user, String password)`** - add a new user with the given password

- **`void addUser(String token, String username, String password)`** - add a new user with the given password

- **`Vector getGroups(String token)`** - gets all groups

- **`boolean hasGroup(String token, String group)`** - checks if a group exists

- **`boolean hasUser(String token, String username)`** - checks if a user exists

- **`boolean addUserToGroup(String token, String username, String group)`** - add a user to a particular group

- **`void removeUserFromGroup(String token, String username, String group)`** - remove a user from a group.

- **`void removeUser(String token, String username)`** - delete a user.

- **`boolean removeGroup(String token, String groupname, String defaultGroupName)`** - remove a group. If `defaultGroupName` is specified, users belonging to `groupname` will be added to `defaultGroupName`.

- **`Vector getGroups(String token)`** - gets all groups

- **`boolean hasUser(String token, String username)`** - checks if a user exists

- **`boolean hasGroup(String token, String groupname, String username)`** - checks if a group exists

- **`boolean editUser(String token, String username, RemoteUser remoteUser)`** - edits the details of a user

- **`boolean deactivateUser(String token, String username)`** - deactivates the specified user

- **`boolean reactivateUser(String token, String username)`** - reactivates the specified user

- **`Vector getActiveUsers(String token, boolean viewAll)`** - returns all registered users

- **`boolean setUserInfo(String token, String username, UserInfo user)`** - updates user information

- **`boolean changeUserPassword(String token, String username, String newPass)`** - changes the specified user's password

- **`boolean changeMyPassword(String token, String oldPass, String newPass)`** - changes the current user's password

- **`boolean changeUserPassword(String token, String username, UserInfo user)`** - updates user information

- **`boolean changeMyPassword(String token, String oldPass, String newPass)`** - changes the current user's password

- **`boolean addUserToGroup(String token, String username, String groupname)`** - add a user to a particular group

- **`boolean removeUserFromGroup(String token, String username, String groupname)`** - remove a user from a group.

- **`boolean updateUserInformation(String token, String username, UserInfo userInfo)`** - update user information

- **`boolean removeUser(String token, String username)`** - delete a user.

- **`boolean removeUser(String token, String username)`** - delete a user.

- **`boolean removeGroup(String token, String groupname, String defaultGroupName)`** - remove a group. If `defaultGroupName` is specified, users belonging to `groupname` will be added to `defaultGroupName`.

### Labels

- **`Vector getLabelsByLabel(String token, long labelId)`** - Returns all Labels for the given ContentEntityObject ID

- **`Vector getLabelsByLabel(String token, String labelName)`** - Returns a Vector of Strings representing the labels for the given spaceKey, with a specified maximum number of results.

- **`Vector getMostPopularLabels(String token, int maxCount)`** - Returns the most popular Labels for the Confluence instance, with a specified maximum number.

- **`Vector getMostPopularLabelsInSpace(String token, String spaceKey, int maxCount)`** - Returns the most popular Labels for the given spaceKey, with a specified maximum number of results.

- **`Vector getRecentlyUsedLabels(String token, int maxResults)`** - Returns the recently used Labels for the Confluence instance, with a specified maximum number of results.

- **`Vector getRecentlyUsedLabelsInSpace(String token, String spaceKey, int maxResults)`** - Returns the recently used Labels for the given spaceKey, with a specified maximum number of results.

- **`Vector getSpacesWithLabel(String token, String labelName)`** - Returns an array of Spaces that have been labelled with labelName.

- **`Vector getSpacesByLabel(String token, String labelName)`** - Returns an array of Spaces that have been labelled with labelName.

- **`Vector getRelatedLabels(String token, long labelId)`** - Returns the content for a given label ID

- **`Vector getRelatedLabels(String token, String labelName)`** - Returns the content for a given label name.
- Vector getLabelContentByObject(String token, Label labelObject) - Returns the content for a given Label object.
- Vector getSpacesContainingContentWithLabel(String token, String labelName) - Returns all Spaces that have content labelled with labelName.
- boolean addLabelByName(String token, String labelName, long objectId) - Adds a label to the object with the given ContentEntityObject ID.
- boolean addLabelById(String token, long labelId, long objectId) - Adds a label with the given ID to the object with the given ContentEntityObject ID.
- boolean addLabelByObject(String token, Label labelObject, long objectId) - Adds the given label object to the object with the given ContentEntityObject ID.
- boolean removeLabelByName(String token, String labelName, long objectId) - Removes the given label from the object with the given ContentEntityObject ID.
- boolean removeLabelById(String token, long labelId, long objectId) - Removes the label with the given ID from the object with the given ContentEntityObject ID.
- boolean removeLabelByObject(String token, Label labelObject, long objectId) - Removes the given label object from the object with the given ContentEntityObject ID.
- boolean removeLabelByNameFromSpace(String token, String labelName, String spaceKey) - Removes the given label from the given spaceKey.

Data Objects

Most returned structs have a summary and a detailed form:

- The summary form is a primary key (ie space key, page id) and a representative form (ie space name, page title)
- The detailed form will have all of the entity details as might be needed for the client.

Unless otherwise specified, all returned structs are in detailed form.

ServerInfo

<table>
<thead>
<tr>
<th>Key</th>
<th>Type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>majorVersion</td>
<td>int</td>
<td>the major version number of the Confluence instance</td>
</tr>
<tr>
<td>minorVersion</td>
<td>int</td>
<td>the minor version number of the Confluence instance</td>
</tr>
<tr>
<td>patchLevel</td>
<td>int</td>
<td>the patch-level of the Confluence instance</td>
</tr>
<tr>
<td>buildId</td>
<td>String</td>
<td>the build ID of the Confluence instance (usually a number)</td>
</tr>
<tr>
<td>developmentBuild</td>
<td>Boolean</td>
<td>Whether the build is a developer-only release or not</td>
</tr>
<tr>
<td>baseUrl</td>
<td>String</td>
<td>The base URL for the confluence instance</td>
</tr>
</tbody>
</table>

Note: Version 1.0.3 of Confluence would be major-version: 1, minor-version: 0, patch-level: 3. Version 2.0 would have a patch-level of 0, even if it's not visible in the version number.

<tr>
<td>buildStats</td>
<td>Map</td>
<td>a Map containing attributes of the build of Confluence running on the node.</td>
</tr>
</tbody>
</table>

### Scripts examples

The [Confluence Extension space](#) contains various examples of scripts.

### Confluence FAQ

**Confluence FAQ**

Solutions to frequently asked questions and queries about Confluence and commonly encountered issues with the product:

**Administration FAQ**
• Capturing HTTP traffic using Wireshark or Fiddler
• Displaying System Properties
• How do I suppress cluster warning message in Confluence?
• How to display a banner like the Confluence Documentation space
• Page Restrictions Performance Considerations
• Using Firebug Lite in Internet Explorer when browsing a Confluence page
• Customising Confluence Icons
• How can I retrieve a recently deleted space or page?
• How do I adjust the session timeout

Capturing HTTP traffic using Wireshark or Fiddler

This is a quick guide to help you start capturing HTTP traffic when requested by support. This can be helpful either for network traffic issues or for understanding issues with page content loading.
**Linux/Unix: Wireshark**

1. Install Wireshark. (Mirror here)
2. Open your Internet browser.
3. Open Wireshark.
4. Click on "Capture > Interfaces". A pop up window will show up.
5. You probably want to capture traffic that goes through your Ethernet Driver. Click on the Start button to start capturing traffic via this interface.
6. Visit the URL that you wanted to capture the traffic from.
7. Go back to your Wireshark screen and click the fourth button or press Ctrl + E.
8. After the traffic capture is stopped, please save the captured traffic into a file (in *.pcap format) and attach it to your support ticket.
9. Don't forget to mention the IP Address of the servers involved so Support can go through the TCP dump.

**Windows: Fiddler**

Wireshark cannot sniff traffic within the same machine (localhost) on Windows. If you would like to sniff local traffic on Windows, try Fiddler.

1. Download Fiddler.
2. Open it.
3. Browse to your site. Visit the pages that are problematic and a contrasting non-problematic page if appropriate, for contrast.

Fiddler can capture local traffic by using the machine's name as the host name rather than 'localhost'.

4. Click File > Save > All Sessions....
5. Attach the resulting file for Support.

**Displaying System Properties**

After adding memory, setting a proxy or changing other java options, it's hard to diagnose whether the system has picked them up.

To find out more about what properties are being picked up, download systemproperties.jsp. Place it in the <confluence-install>/confluence/admin folder. Access the URL: http://<yourbaseurl>/admin/systemproperties.jsp.

No restart of Confluence is required.

**How do I supress cluster warning message in confluence?**

You might find that under Logging and Profiling in Confluence Admin, either (or both)

```
com.atlassian.confluence.cluster.safety
com.atlassian.confluence.cluster
```

are set to DEBUG.

Please change them to INFO and the warning messages in logs should disappear.

**How to display a banner like the Confluence Documentation space**

The documentation for spaces prior to the current documentation contain a banner:

Edit the main layout for the space. After the Content div header:

```jsp
## CONTENT DIV BEGINS
<div id="header">
#quickSearch()
<ul id="header-menu-bar" class="ajs-menu-bar">
#if($sitemeshPage.getProperty("page.browse-menu"))
$sitemeshPage.getProperty("page.browse-menu")
#else
#menuMacros_renderGlobalBrowseMenu()
#end
#menuMacros_renderUserMenu()
$!sitemeshPage.getProperty("page.breadcrumbs")
</ul>
</div>
```

Add the following:
Page Restrictions Performance Considerations

Page Permissions and the Confluence Search Index

Modifying the page permissions requires reindexing all child pages, as well as comments and attachments on all those pages.

The reasons for this:

- Page permissions are stored on every item in the index
- When you search, a filter is applied to all items in the index which prevents you seeing content you don't have permission to see
- If the permission information on attachments wasn't updated when a page permission was changed, users who didn't have permission to view the attachment in Confluence would still see that attachment in the search results as well as some of its content
- To update any record in the index, you need to delete it from the index and re-add it (this is a limitation of Lucene)

Therefore, to update an attachment record in the index, even just to change the permissions, the attachment's content must be reindexed.

Performance Considerations

In the large majority of situations, this design should not be a problem. In large spaces with deep page hierarchies, it might be. Use performance logging for the index flush operation to assess the impact of changing a page restriction - try it on the space's home page, or a page with a lot of children, to see the performance impact of changing a page restriction.

Space Design Considerations

For some space designs, deep page hierarchies may be desirable. If possible, it's recommended to split spaces where it makes sense to do so, according to how your information is organized. One workaround – CONF-7089 – involves opening up access to just a few pages in a mostly-restricted space so as to "open" the space where space permissions close it. This may be a performance concern if the space, and attachments in the space, are large.

Workarounds

There are a few workarounds to consider:

1. Avoid page restrictions on large page hierarchies. If you have a large hierarchy you have to protect differently to other content in the space, consider moving the hierarchy to a new space. (Space permissions are applied in a manner that doesn't have this problem, but having a large number of spaces also causes scaling issues.)
2. Disable page permissions completely. You can do this on a space-by-space basis by not granting the "Restrict" permission in the space permissions screen.
3. Turn off attachment content indexing. See How do I disable indexing of attachments or Configuring Attachment Size for information on how to do attachment types or size limits.

Using Firebug Lite in Internet Explorer when browsing a Confluence page

1. Open a Confluence page in IE.
2. Copy and paste the following into your IE browser URL bar and press enter:

   ```javascript
   javascript:var%20firebug=document.createElement('script');firebug.setAttribute('src','http://getfirebug.com/releases/lite/1.2/firebug-lite-compressed.js');document.body.appendChild(firebug);(function(){if(window.firebug.version){firebug.init();}else{setTimeout(arguments.calleen);}})();void (firebug);
   ```

3. You should see a Firebug console at the bottom of the browser now.

For more information, please refer to Firebug Lite's documentation

Customising Confluence Icons

Icons are intended to be added/customised from time to time by users to adopt a new look. The file locations are hard to locate.

Resolution
These steps are under the presumption that users have access to the source code:

- Search for the atlassian-renderer library.
- Extract the library and search for the file /com/atlassian/renderer/DefaultIconManager.java where the icons are being mapped.
- Check out how the referencing are being done there and add your own icons within

The Confluence 2.10 version of CONFKB:DefaultIconManager is attached to this article.

Additional Information

<table>
<thead>
<tr>
<th>Severity</th>

<tr>
<td>Regular Expression</td>
<td>[Cc]ustom.*icon</td>
</tr>
<tr>
<td>Article ID</td>
<td>CONFKB151519281</td>
</tr>
</tbody>
</table>

Searching Confluence Knowledge Base

How can I retrieve a recently deleted space or page?

To restore a page, you may find the wanted information in the Restoring a Deleted Page documentation.

Unfortunately there is no easy way to restore a space - tell your Confluence Administrator to restore the site's daily backup and retrieve the deleted space from there.

To setup Confluence in a staging environment you may need to use a Developer License.

How do I adjust the session timeout

To change the default session timeout (which is 60 minutes) you must edit the file web.xml. This file can be found in <YOUR DEPLOYMENT>/confluence/WEB-INF/web.xml.

The element you want to edit in the web.xml file is:

```xml
<session-config>
    <session-timeout>60</session-timeout>
</session-config>
```

The value within the session-timeout tag defines the amount of time the session will exist, in minutes.

Note that after editing the web.xml file you will need to restart confluence for your change to take effect.

On a related note, to configure Confluence's internal connection pool timeout period, please tweak the c3p0.timeout property in your <Confluence-Home>/confluence.cfg.xml file:

```xml
<property name="hibernate.c3p0.timeout">30</property>
```

This value is an indication of the number of seconds a connection can remain pooled but unused before being discarded. Zero means idle connections never expire.

More details can be found here.

How Do I Find My License from the File System?

If you're not sure where your license is in my.atlassian.com, you can look in <confluence-home>/confluence.cfg.xml.

How do I Remove a User who has Content Created

Confluence doesn't allow the removal of a user who has created any content. The standard method for removal is described in Removing a User. If you want to delete the content as well, the SQL is described below. Locate the content created by the user using the queries:

```sql
SELECT * FROM CONTENT WHERE contenttype = 'COMMENT' and creator = '<Username that you wish to remove>'
```
Run the same DELETE commands after verifying the content is indeed content you wish to delete.

### How do I Remove the Last Updated and Created By Text?

Open the file `<confluence-install>/confluence/decorators/includes/page-metadata.vm` in a text editor and remove the following text:

```text
#if ($page.isLatestVersion() == true)
$action.getText('added.by.user.last.edited.on.date', ["#$usernameLink ($page.creatorName)", "$action.dateFormatter.format($page.lastModificationDate)"])
#set ($previousPage =$action.getPreviousVersion($page.previousVersion))
#if ($previousPage)
   <$span class="noprint">&nbsp;(<a href="$req.contextPath/pages/diffpages.action?pageId=${page.id}&originalId=$previousPage.id">$action.getText('view.change')</a>)</span>
#end
#else
$action.getText('added.by.user.edited.on.date', ["#$usernameLink ($page.creatorName)", "$usernameLink ($page.lastModifierName)", "$action.dateFormatter.format($page.lastModificationDate)"])
#end
```

### How to Disable Emoticons

The text markup `i` is rendered as ![ ], a principle which applies to many more Confluence Emoticons. There is a feature request at CONF-4884 for enabling or disabling emoticon rendering in this manner via Confluence’s Administrative features. However, to disable emoticon rendering in Confluence:

#### For Confluence 2.8.x and earlier:

1. Open up the `wikiFiltersSubsystemContext.xml`:
   - For Confluence 2.5.x and earlier, this file is located in `WEB-INF/classes` directory.
   - For Confluence 2.6.x to 2.8.x, this file is located in `WEB-INF/lib/confluence-2.x.y.jar/plugins`. Please follow the steps as suggested here to edit files in a jar file.
2. Determine the following line and remove/comment out the content:

   ```xml
   <ref local="emoticonRendererComponent"/>
   ```

#### For Confluence 2.9.x and later:

1. Open up the `wiki-renderer-components.xml`, located in `WEB-INF/lib/confluence-2.x.y.jar/plugins`. Please follow the steps as suggested here to edit files in a jar file.
2. Determine the following line and remove/comment out the content:

   ```xml
   <renderer-component key="emoticon" name="Emoticon Renderer"
   class="com.atlassian.confluence.renderer.plugin.SpringRendererComponentFactory" weight="10000">
   <param name="componentName">emoticonRendererComponent</param>
   </renderer-component>
   ```

Alternatively, manually escape the character with a “slash”, “\”. For example:

```
\(i)
```

**Code Macro** and **Noformat Macro** is also an option as any emoticons wrapped within the macro will be disabled automatically.

### How to Hide the Referrer

Run Confluence over SSL. Major browsers do not send the HTTP_REFERER when you are linking from an https:// site to an http:// site. To run confluence on SSL please refer to Adding SSL for Secure Logins and Page Security.

### Additional Information
How to Restore Deactivated Users

**Symptoms**

A user that has been deactivated in the past cannot be brought back to life. Even if assigned to the right groups with confluence access.

![Note that this applies only to the older mechanism for user deactivation. In newer versions of Confluence, users are removed by removing them from groups with can-use permission, as described in Removing a User.]

**Cause**

In older versions of Confluence users have been deactivated by inserting a row into table os_propertyentry with entity_id = theUserId AND entity_key=confluence.user.deactivated

This entry is still evaluated but there is no mechanism in newer version to remove this from the DB.

**Resolution**

1. Backup Confluence
2. Stop Confluence
3. Find the user id (=theUserId) of the particular user in table users
4. Run the following SQL query to identify the row that contains the 'deactivated' information. The entity_name column should have an entry like 'LOC_username':

   ```sql
   select * from OS_PROPERTYENTRY WHERE entity_id = theUserId AND entity_key="confluence.user.deactivated";
   ```

5. Delete this row from the table

**Additional Information**

![Searching Confluence Knowledge Base]

How to Search Confluence for Uses of a Macro

**Illegal Search Terms**

Several terms are illegal to use when searching Confluence, like : or {. If you search for just the macro term, you're likely not to get the right search results. For example, searching for 'usage', which is the name of a macro but also a common English word, will not yield an accurate count.

**Query the Database**

If, for example you want to search for the uses of the usage macro, you can search the database:
For large instances of Confluence, searches across the entire bodycontent table of the database might be expensive. You can try this on a test server.

You might want to use the SQL Plugin to automate this, or better yet the Macro usage stats plugin. Note that these are third party (unsupported) plugins.

```
SELECT * FROM BODYCONTENT WHERE BODY LIKE '%{usage}%' 
```

If you want to get the last users or the creators of the pages where the `noformat` macro is used, you might run:

```
SELECT CREATOR FROM CONTENT WHERE CONTENTID IN (SELECT CONTENTID FROM BODYCONTENT WHERE BODY LIKE '%{noformat}%' ) GROUP BY CREATOR 
SELECT LASTMODIFIER FROM CONTENT WHERE CONTENTID IN (SELECT CONTENTID FROM BODYCONTENT WHERE BODY LIKE '%{noformat}%' ) GROUP BY LASTMODIFIER 
```

**Logging Uses of a Macro**

This information won’t tell you how often a macro is invoked - rather how often it appears on pages. For counting how often it’s invoked (and measuring the time it takes to invoke it), check Identifying Slow Performing Macros.

**Counting the Incidents of Invoked Logs**

You can then grep the logs like:

```
grep -c "{usage}" atlassian-confluence.log
```

**Where are the files that used to be in my Confluence installation directory?**

With the release of Confluence 2.6.0, many files have been moved inside `WEB-INF/lib/confluence-x.x.x.jar` file, which means they can no longer be edited by simply opening and saving a file.

For example, you may find that some files previously were in `<confluence install directory>/confluence/WEB-INF/classes` are no longer there.

If you want to edit them for customisation, you will need to extract the relevant files from the `confluence-x.x.x.jar`, and place them in the directory where they are used to reside.

You can either use a zip application or use the `jar` tool from your JDK installation to extract the file.

**Example**

You want to modify `xwork.xml` in Confluence 2.10.2. The steps to follow are:

1. Shutdown Confluence
2. Locate `WEB-INF/lib/confluence-2.10.2.jar`.
3. Open the jar file using your favourite zip application and search for `WEB-INF/lib/confluence-2.10.2.jar/xwork.xml`. You can also use JAVA’s `jar` tool if you like.
4. Extract `xwork.xml` and place it in `WEB-INF/classes/`, and modify as necessary. Any files placed in this folder will take precedence over their jarred version and you do not need to re-jar them in `confluence-21.0.2.jar`.
5. Restart Confluence

The problem with customization is that they might break in the new version of Confluence. Some codes in your customized file might have changed in the new version. Hence, it is best that you do not copy your customized file directly to the new installation directory. Instead, you need to apply the same customization in the new version of the file.

**RELEVANT TOPICS**

- Editing Files within JAR Archives
- Installing Patched Class Files
Where are user macros stored?

User macros are stored in the bandana table:

```
select * from bandana as b where b.bandanakey = 'atlassian.confluence.user.macros';
```

Add Spell Checking To Confluence

Confluence has no inbuilt support for spell checking. You may wish to vote for Confluence to add its own spell checking or add spell checking to your browser instead:

- Add spell checking to Internet Explorer
- Install the Firefox browser with inbuilt spell checking

Can I run multiple instances of Confluence & connect them to a central database?

Confluence can be **clustered**.

If running as a single node, you may only have one instance of Confluence connecting to a single database.

There are a couple of reasons for this, but it all comes down to the fact that the Confluence application maintains a lot of state (caches, search indexes) separate to the database, and multiple front-ends will quickly see that state get out of sync, with disastrous effect.

Because of this, Confluence periodically checks to make sure it’s the only application accessing the database, and if it finds a conflict it will shut down rather than risk corrupting your data.

Configuring Confluence to send email notifications

Configuring Confluence to send email notifications requires a Confluence Administrator to set this up through the Administration Console.

To configure Confluence to send notifications and test that it is working, follow these instructions:

1. Set up a mail server at Administration -> Mail servers. See Configuring a Server for Outgoing Mail.
   - Make sure you use "Send Test Email" to check that the server is working. Check that you get the test email in your inbox.
2. Go to your profile (using the Preferences link) and click Edit Profile -> Email Preferences, then enable Notify On My Action. (Otherwise you’ll have to use multiple users. By default confluence does not send you notifications for your own changes.) See Managing Watches
3. While editing your profile, make sure you have an email address configured. See Configuring a Server for Outgoing Mail
4. Go to a page you wish to get notifications about.
5. Click the Envelope icon in the top right corner to "watch" that page. See Watching a Page.
7. Either wait a while or: Go to Administration -> Mail Queue. Click "Flush Mail Queue". See The Mail Queue.
8. Check your email.

For instructions on configuring user-level email notifications, see Setup email notifications of page updates.

**RELATED TOPICS**

Setup email notifications of page updates

Copy Or Rename A Space

Currently Confluence does not support renaming or copying spaces through the user interface. You may wish to vote towards these feature requests:

- Feature request to clone an entire space - this will enable duplication of every page, news item and comment plus space themes and colour schemes.
- Feature request to copy a page hierarchy between existing spaces.

**Use The Copy Space Plugin**

The best option is to install the Copy Space Plugin.

⚠️ Note that this plugin is still in beta release, and is not officially supported by Atlassian.

⚠️ Note that copying a space can take a long time and may appear to time out when using this plugin (even when the copied space is created correctly). If this occurs, please ensure that your space has not been created before attempting to copy the space again.

Read the developer’s notes in the Atlassian blogs.

**Manually Clone Or Rename A Space**
Alternatively, it is possible to manually clone or rename a space by modifying an XML backup of the target space.

Notes

- May require manually updating external links to that space.
- The instructions have been confirmed for Confluence 2.2 onwards. Users running older versions are recommended to upgrade Confluence before continuing.
- Where examples are given, they involve changing oldkey:Old Space Name into newkey:New Space Name. You need to substitute your own keys for oldkey and newkey, and your own space names for Old Space Name and New Space Name.
- When importing a space export for a space that already exists, the previous space content will be overwritten.
- Read the process in full before beginning.

Stage 1: Rename Space

1. Select a new, unique space key and name for the second space. Space keys may only consist of ASCII letters or numbers (A-Z, a-z, 0-9) and no empty spaces are allowed in the key.

2. Clone your production Confluence instance to a test server on another computer now. (For instructions, see Migrating Confluence Between Servers.) You should now have a production server and test server both containing the same data and can avoid the risk of corrupting your production Confluence instance.

3. On the test server, login as an administrator.

4. Go to Browse Space -> Advanced -> Export Space and export the target space as XML including attachments.

5. Save the space backup.

6. Open the space backup file with a zip file editor and find the file entities.xml.

7. Edit entities.xml in a text editor.

8. Do a 'Search & Replace' on the old space name as shown below. Swap out Old Space Name and New Space Name for the actual names.

<table>
<thead>
<tr>
<th>Search For</th>
<th>Replace With</th>
</tr>
</thead>
<tbody>
<tr>
<td>[CDATA[Old Space Name]]</td>
<td>[CDATA[New Space Name]]</td>
</tr>
</tbody>
</table>

9. Do a 'Search' for any occurrences of the old space name that occur in user content. You may wish to replace some or all of these references with the new space name. Replace Old Space Name and New Space Name with the actual names.

<table>
<thead>
<tr>
<th>Search For</th>
<th>Replace With</th>
</tr>
</thead>
<tbody>
<tr>
<td>Old Space Name</td>
<td></td>
</tr>
</tbody>
</table>

10. Do four 'Search & Replaces' on each of the references to the old space key as shown below. Swap out oldkey and newkey for your actual keys.
### Search For vs Replace With

<table>
<thead>
<tr>
<th>Old Key</th>
<th>New Key</th>
</tr>
</thead>
<tbody>
<tr>
<td>[oldkey]</td>
<td>[newkey]</td>
</tr>
<tr>
<td>spaceKey=oldkey</td>
<td>spaceKey=newkey</td>
</tr>
<tr>
<td>[oldkey::]</td>
<td>[newkey::]</td>
</tr>
<tr>
<td>key=oldkey</td>
<td>key=newkey</td>
</tr>
</tbody>
</table>

**For example:**

Space name: Test Space  
Space key: test  
New space name: Test Space 2  
New space key: test2

```xml
<property name="name"><![CDATA[Test Space]]></property>
<property name="key"><![CDATA[test]]></property>
```

The above search and replace ensures that you will change the test oldkey to test2, and change the "Test Space" Old Space Name to Test Space 2.

11. Save the modified `entities.xml`.

12. Overwrite the original `entities.xml` in the space backup with the modified version.

13. Login to the test instance as a Confluence administrator.

14. Go to Administration -> Backup & Restore. Under 'Upload a zipped backup to Confluence', browse to select to the modified space backup. Check the 'Build index' option and select 'Upload & Restore'.

15. Once the restore process has completed, access the new space and test that you can access pages, embedded links and attachments. Any error in this step indicates that your search and replace was performed incorrectly and you should retry from step 2.

### Stage 2: Restore On Production

1. Backup your production instance now.

2. Login to the production instance as a Confluence administrator.

3. Go to Administration -> Backup & Restore. Under 'Upload a zipped backup to Confluence', browse to select to the modified space backup. Check the 'Build index' option and select 'Upload & Restore'. If any data loss occurs as a result of using this workaround, immediately revert to the backup.

4. Once the restore process has completed, access the new space and test that you can access pages, embedded links and attachments. If any error occurs during this step, revert to the site backup.

5. If renaming a space, you can delete the old space by going to Browse Space -> Space Admin -> Remove Space. Click OK to remove the old space.

### Stage 3: Rename Space References

Links in other spaces to the old space will remain unchanged. If you are renaming a space, you will need to change these links to point to the new space. Users who are copying a space can leave the links pointing to the original space by skipping this stage.

Changing these links depends on if you want to change every link, or only some. If not all links must be changed or you are unwilling to stop your production instance, this must be done by editing each page individually. If all links must be changed, follow the instructions below.

1. Create a site XML backup including attachments from Administration -> Backup & Restore.

2. Save the site XML backup file.

3. Stop the production instance.

4. Create two copies of the site backup. Keep one copy as the original, unmodified backup, the other will be modified. Rename the backups so that it is clear which is being modified.

5. Open the copy for modification and edit `entities.xml`.

6. Do four `Search & Replaces` on each of the references to the old space key as shown below. Swap out oldkey and newkey for the actual keys.
Confluence 3.0 Documentation

<table>
<thead>
<tr>
<th>Search For</th>
<th>Replace With</th>
</tr>
</thead>
<tbody>
<tr>
<td>[oldkey]</td>
<td>[newkey]</td>
</tr>
<tr>
<td>spaceKey=oldkey</td>
<td>spaceKey=newkey</td>
</tr>
<tr>
<td>[oldkey:]</td>
<td>[newkey:]</td>
</tr>
<tr>
<td>key=oldkey</td>
<td>key=newkey</td>
</tr>
</tbody>
</table>

7. Save the updated `entities.xml` back into the modified site XML backup file
8. Start the production instance
9. Import the modified site XML backup from Administration -> Backup & Restore. If you have any problems, revert to the original unmodified backup and redo the links manually instead

Done.

## Getting a License for a Staging Environment

If you already have a developer license, you can [add it under the Administration > License Details page](#). You can also create a new key as detailed below:

> Only a technical contact for your commercial/academic license is able to create a Developer license

Atlassian supplies 'developer' licenses which can be used by existing commercial license holders who wish to deploy non-production installations of our software to use in QA/staging environments. Developer licenses are free of charge to commercial license holders and, like our commercial offerings, they include 12 months of updates starting from the date of purchase of the commercial license.

If you hold a commercial license, you can obtain a free developer license by performing the following:

1. Log in to your Atlassian account.
2. Under the "Licenses" heading, all of your licenses will be displayed. Click the plus sign next to a license to view its details.
3. Click the "View Developer License" link in the bottom right corner of the license detail panel, below your commercial license key.

Your new developer license will be generated and displayed in a pop up window. Repeat this process as many times as necessary for multiple developer licenses. If you're unable to create the license, [contact our sales department for help](#).

### Developer licenses are not compatible with all versions of our products. The table below indicates which versions of each product support developer licenses.

<table>
<thead>
<tr>
<th>JIRA</th>
<th>Confluence</th>
<th>Bamboo</th>
<th>Clover for Ant</th>
<th>Clover for Eclipse 3</th>
<th>Clover for IDEA 6</th>
<th>Crowd</th>
<th>Crucible</th>
<th>FishEye</th>
<th>JIRA Perforce Plugin</th>
<th>JIRA VSS Plugin</th>
</tr>
</thead>
<tbody>
<tr>
<td>3.7+</td>
<td>2.3+</td>
<td>All</td>
<td>1.3.14+</td>
<td>1.2.12+</td>
<td>1.0.2+</td>
<td>All</td>
<td>1.0.3+</td>
<td>1.3.3+</td>
<td>JIRA 3.11+ (Disabled)</td>
<td>JIRA 3.11+</td>
</tr>
</tbody>
</table>

If you are working with an older version that doesn't recognize developer licenses, you can use your existing commercial license in your test environment.

## How do I change the space key?

See [Copy Or Rename A Space](#).

## How do I check which spaces have email accounts

If you have numerous spaces in Confluence and would like to check for spaces which have a mail setting, you can run a database query like the one below:

```sql
SELECT spaces.spacename, spaces.spacekey, bandana.bandanakey
FROM spaces, bandana
WHERE spaces.spacekey = bandana.bandanacontext AND bandana.bandanakey = "atlassian.confluence.space.mailaccounts";
```

## How do I Disable Automatic Mail Polling?

**RELATED TOPICS**

- How do I configure the Plugin Repository to update its plugins information offline?

With the launch of [plugins.atlassian.com](http://plugins.atlassian.com), the Confluence Plugin Repository SVN metadata has been deactivated. For existing clients,
requests to confluence.atlassian.com for repository metadata are now transparently redirected to plugins.atlassian.com, which provides up-to-date plugin information in the same XML format as that served from the old repository proxy.

While Confluence installations with access to confluence.atlassian.com see no impact from this change, those installations which cannot access confluence.atlassian.com need special instructions.

**Download the latest plugins.atlassian.com XML for your version of Confluence**

PAC makes the plugin repository client data available at the URL

https://plugins.atlassian.com/server/legacy/confluence/xml

where `<bn>` is the build number of the Confluence installation. The build number is visible at Admin -> System Information (near the bottom of the page). Build numbers for all released Confluence builds are also available here.

Save the resulting file and place it on a Web server accessible from Confluence. This can be the same server as Confluence itself; for example, if you’re running the standalone version of Confluence at http://localhost:8090, place the saved XML in the confluence directory inside your standalone installation.

**Keeping the XML up to date**

When a change is made on plugins.atlassian.com to a plugin’s data, the generated XML will update at most one day after the change is made. Consider writing a cron job or similar to fetch the XML on a weekly basis and store it in your chosen location to ensure you are always up to date on plugin information.

**Configure the Plugin Repository Client**

Now go to Admin -> Plugins -> Confluence Atlassian Plugin Repository and click on the Configure link.

There are four plugin repository data source options:

1. **HTTP Data Source Generator** - Plain text XML file served over HTTP. Never used, except for debugging.
2. **Subversion Generator (Deprecated)** - Check out the metadata from SVN and generate the XML internally. As this uses the deprecated SVN metadata, it can be ignored.
3. **Local Generator (Deprecated)** - Read the metadata off your local filesystem and generate the XML internally. As this uses the deprecated SVN metadata, it can be ignored.
4. **Proxy Client** - pull XML data from another Confluence Plugin Repository Client that has been configured to act as a server.

In this case you would need to choose the **Proxy Client** option, as it is able to fetch XML from any server, not just plugins.atlassian.com.

Paste the URL to the XML data in the **Data Source** field and uncheck the **Data Source Proxying** option if it is checked. Then click **Save** and select **Admin -> Plugin Repository**, and the client should load the repository info as before.

**RELATED TOPICS**

Confluence Repository Client

**How do I disable indexing of attachments**

Sometimes a user can experience problems indexing large MSExcel or MSPowerPoint documents and the reindexing may cause potential Unknown Ptg warning messages that are harmless. There is already a request to Suppress these warnings from the re-indexing of unreadable documents by the POI library.

The error is usually not serious yet can sometimes cause problems when large attachments are used. So you may like to disable indexing of a particular type of document.

To do this, you can use one of the methods described below.

**Method 1: Via the Administration Console**

You can disable the relevant modules from the Attachment Extractors plugin, by going to Administration -> Configuration -> Plugins -> Attachment Extractors and disabling the relevant modules listed there:

- PDF Content Extractor — For PDF attachments
- MS Word Content Extractor — For DOC attachments
- MS Excel Content Extractor — For XLS attachments
- MS PowerPoint Content Extractor — For PPT attachments

The search query will ignore all attachments of the type corresponding to the disabled module.
Method 2: Via editing the attachment-extractors.xml file

You need to modify the confluence/WEB-INF/classes/plugins/attachment-extractors.xml and comment out the relevant file type extractor. From Confluence 2.6, attachment-extractors.xml is packaged inside confluence-2.6.0.jar, we have instructions for Editing Files within JAR Archives if you're unfamiliar with the process.

The example below shows a pdfContentExtractor disabled which would cause PDF attachments not to be indexed.

Once the ContentExtractor for a file type is disabled, all files of that type become unsearchable.

How Do I Get More Statistics From Confluence?

Confluence has several plugins that you can use for generating statistics, such as:

- Use the SQL and Chart plugins together.
  - Our user community have contributed some great SQL queries.
- The Reporting Plugin contains macros which allow powerful and flexible reporting on Confluence content and content from other locations.
- Customware's Tracking Plugin contains macros for anonymously tracking content access. Otherwise known as hit counting, this macro provides the ability to count the number of times a given piece of content has been viewed. It does not count views by the most recent editor of the page.
- Try using the tracking-info macro to track the number of times an attachment is downloaded
- Make user macros like countpages, which counts the number of pages in a space.
- Use the Contributors and Contributors Summary macros to get more details regarding the contributors for required pages.
- Statistical Analysis Plugin from Adaptavist, is another cluster-ready, enterprise scalable third-party plugin.

In addition, Confluence has a built-in access logging mechanism, which shows who has logged in and the URL invoked. To enable it, you need to modify a couple of configuration files and restart Confluence. The traditionally generated access log can then be analysed by one of the available access log analyser tools such as Webalizer, Google Analytics or AwStats which can generate useful statistics.

For more information on using Google Analytics and Confluence you may wish to refer to this blog post by David Simpson.

See our documentation on Obtaining Confluence Instance Metrics

If none of the above tools satisfy your requirements, you can create a feature request in jira. Please note that there are already several feature requests and improvements created by our customers all being collated under one umbrella issue

Please cast your vote, add your comments to the discussion and don't forget to add yourself as a watcher to be notified on progress. All our improvements and new features are implemented according to this guide.

**How do I know what Confluence version I am running?**

At the bottom of a Confluence page you will see a line like this:

```
Powered by Atlassian Confluence 2.10.1, the Enterprise Wiki. Bug/feature request - Atlassian news
- Contact administrators
```

In the above it means that you are running Confluence version 2.10.1.

If you do not see that line, you can visit [http://<Your Confluence URL>/admin/systeminfo.action](http://<Your Confluence URL>/admin/systeminfo.action) and find out the version from there.

**How do I prevent personal spaces from being shown on the dashboard**

To disable personal pages from being shown in the dashboard one will need to customise the recently updated content macro by giving it a different parameter.

Here's how:

1. Login as an admin and go to your Confluence administration console
2. Under the "Look and Feel" menu, click on "Layouts" (or type this in your browser: [http://yourConfluenceURL.com/admin/listdecorators.action](http://yourConfluenceURL.com/admin/listdecorators.action))
3. Under "Site Layouts" look for "Global Layouts" and choose "Create Custom"
4. In the layout editor, look for this line:

   ```
   $helper.renderConfluenceMacro("{recently-updated:dashboard|showProfilePic=true}")
   ```

5. Change to this:

   ```
   $helper.renderConfluenceMacro(
       "{recently-updated:spaces=SpaceKey1,SpaceKey2|showProfilePic=true}"
   )
   ```

6. Save

   ![Warning] Personal spaces will still show up in daily email update. If you don't want this to show in the email update, you need to make the space accessible only to selected groups or people.

**List page- and space-related details for an attachment using the attachment's name**

Occasionally, the indexing task will report some attachments that failed to be indexed correctly. If you wish to list the page- and space-related information for these problematic attachments (of which you only know their title from the logs) please query your database with the following SQL statement:

```sql
select s.spacekey, s.spacename, a.title, a.pageid, a.attachmentid, 
    '(confluence-home)/attachments/' + a.pageid + '/' + a.attachmentid + '/' + a.attversion as filepath
from attachments a
join content c on a.pageid = c.contentid
join spaces s on c.spaceid = s.spaceid
where a.title like '<Name of Attachment>'
```

Please substitute the attachment name in the above query depending upon your requirement.

The `filepath` column will list all attachments in the directory structure format similar to the way that they are stored in Confluence, such as `<Confluence-Home>/attachments/pageid/attachmentid/attachmentversion`

**Related Unix Commands**

```
file <Filename>
```

If you wish to check the filetype for attachments in your `<Confluence-Home>/attachments/` folder, run the above Unix command.

Eg:
Migrate Confluence from one database to another

How do I migrate Confluence from one database to another?

First perform an XML backup of your Confluence site. You can do this from the Administration > Backup and Restore page.

Once you've made the backup file, you can set up a new Confluence instance from scratch against your new database and restore the backup that you just created. Detailed instructions can be found here.

FAQ Home

Rebuild the Content Indices from scratch

Why are the Content Indices failing?

The Content Indices (consisting of either the Search Index or the Did You Mean Index) may become corrupt and fail due to the following causes:

- Confluence runs out of memory.
- Confluence runs out of disk space.
- Permissions are incorrect in the <confluence-home>/index directory.
- The index flush trigger is not synchronized, and an environmental issue like system time is reading the flag incorrectly (bug is reported at CONF-9575, fixed in Confluence 3.0.2).

For an analysis of why your index might have failed, please create a Support ticket. Make sure to attach your atlassian-confluence.log.

Flushing the Index Queue

You may be able to address the issue without a complete rebuild of the index. When you experience search problems within your Confluence instance, or cannot find things after performing an upgrade, one simple solution that can help you locate your content is to manually rebuild the index, as described in Content Index Administration. You can try either a complete rebuild, or flush the queue contents.

Rebuilding the Failed Content Indices

If you are still experiencing problems after performing the above rebuild, the next step may be to remove the index and rebuild it from scratch, as described below. For example, the rebuild procedure described above may not restore a corrupted index file. You may want to ensure that all index files are re-created.

The Space Activity feature uses the index to store data. To preserve the activity data, keep the Plugins directory and delete the rest of the index.

To remove the index and rebuild it from scratch:
1. Shut down your Confluence server.
2. Remove the `<confluence-home>/index` directory.
3. Restart server.

   A new index directory will be created upon restart of your application.
4. Now perform the manual re-indexing of your site to build a brand new index from scratch.

If you still cannot find your content, please contact Confluence support.

**Redirect users to a site-wide home page after a successful login**

As an administrator, you can set a site-wide home page within any space, to which users are sent after logging in.

To set the site-wide home page as an administrator:

1. Go to Administration > General Configuration
2. Click Edit
3. Set Site Homepage to your desired home page

Setting home pages within spaces depends on the access permissions to both the space and your site.

- If your site allows anonymous access, the site homepage must also be accessible anonymously.
- If your site does not allow anonymous access, the site homepage must be accessible to the "confluence-users" group.

In Confluence 1.2 and earlier, the site homepage must be accessible anonymously, regardless of site permissions.

**Note:** please ensure that the View Space Goes to Space Summary setting is set to OFF if you want users to be sent to space homepage instead of the summary page.

For instructions on configuring this feature at the user level, see Redirect to a specific page (home page) within the site after logging in.

**RELATED TOPICS**

Redirect to a specific page (home page) within the site after logging in

**Redirect users to a page on login**

*Can I set Confluence to redirect users to a space homepage immediately after login?*

Yes. You can direct users to any of the space homepages when they login to the site. This is configured by a site administrator from the Administration Console. Instructions on how to do this can be found here.

You can also modify the login page's content or establish single sign-on integration.

**RELATED TOPICS**

Administration Guide
Customising Space Homepage

**Restrict Attachments Based On File Type**

If a user has permission to upload attachments, you can restrict them to certain filetypes only by installing the Attachment Filter. Note that this is an unsupported plugin and has only been tested to work on Confluence 2.2 - 2.3.x. There is an open new feature request to have this updated and supported here.

You can also restrict the maximum size of any one attachment that a user can upload, or disable the indexing of attachments, which may help performance.

**Search for User Properties in the Database**

So long as you have not changed the user authentication from the default (i.e. you are NOT using external user management such as LDAP or JIRA) the users of Confluence are stored in `OS_USER` table.

The user's properties such as fullname, email and when they previously logged in, are stored in the `OS_PROPERTYENTRY` table.

If you know the user's username (which can be found in `OS_USER` table), you can find their details using the following query:

```
select * from os_propertyentry p, os_user u where p.entity_id = u.id and u.username='user_name_goes_here';
```
Fix Out of Memory errors by Increasing Available Memory

Since the default memory setting usually is around 64 or 128MB (256MB in Confluence 2.2 and later), you might have to adjust the settings to run a bigger Confluence instance with sufficient memory.

On this page:

- Diagnosis and Common Causes
- Determining the various causes of memory errors
  - java.lang.OutOfMemoryError: PermGen space
  - java.lang.OutOfMemoryError
  - OutOfMemoryError: unable to create new native thread
  - OutOfMemoryError: GC overhead limit exceeded
  - OutOfMemoryError: Requested array size exceeds VM limit
- Setting the Memory Settings

Diagnosis and Common Causes

There are several reasons that out of memory exceptions can be thrown. Either the virtual machine Confluence is using has hit its allocated memory limit, the system on which Confluence is running has run out of physical and virtual memory, or Confluence is consuming too much memory. In the first case, you should modify the maximum heap size of the virtual machine, per the instructions in this document; in the second or third cases, the solution is to identify the culprit of the memory leak.

For help determining which memory settings to choose, consult Managing Application Server Memory Settings.

If you have not yet set your memory settings and your usage has increased, it's likely that you must set your memory, described below. If your usage patterns have not changed but you've added a plugin or done an upgrade, it's likely that there is a memory leak in a plugin.

1. If you're using the in-memory database (HSQLDB), migrate to an external database. The in-memory database can use a lot of memory.
2. If you are using XML backups, disable them and move to the Alternative Backup Strategy. The XML backup process can be a memory hog.

To troubleshoot potential memory leaks, enter Plugin Support Mode. Take thread dumps during normal operations and during an outage, and submit this information in a support ticket.

Determining the various causes of memory errors

There are different kinds of memory limits inside the Java Virtual Machine. Each limit can be configured independently. But you must first find out which limit you have reached.

java.lang.OutOfMemoryError: PermGen space

If you get the error message: java.lang.OutOfMemoryError: PermGen space this means that you have exceeded Java's default 64Mb block for loading class files. This can happen if many plugins are installed. You may want to increase the PermGen memory size to suit your needs.

In the following sample, the blue parameter shows how the PermGen Memory has been set to 192 megabytes. This value should be set depending on your memory requirements. 192m should be sufficient for Confluence even when many plugins are installed.

JAVA_OPTS="-Xms128m -Xmx1024m $JAVA_OPTS -Djava.awt.headless=true" -XX:MaxPermSize=192m

Note: The other parameters in this sample are just shown to give you some context, and are not part of this example.

java.lang.OutOfMemoryError

Heap space memory errors occur when the application has to deal with large amounts of data or users. These errors will contain only a java.lang.OutOfMemoryError, e.g. without the reference to PermGen space as above. You should try to increase the heap size to solve this problem. This requires configuring the Xmx and Xms parameters. In the following example, the maximum heap size is set to 1024 megabytes. This should be enough for small to medium deployments.

JAVA_OPTS="-Xms128m -Xmx1024m -XX:MaxPermSize=256m $JAVA_OPTS -Djava.awt.headless=true"

Note: The other parameters are only shown to give you context and are not part of this example.
Deployments with high usage patterns may require additional memory. For high-usage deployments, it is recommended to set both Xms and Xmx as the same value (e.g. -Xms1024m -Xmx1024m), provided the memory is available. On the other hand, adding too much memory can also cause problems (see below), so you should increment memory carefully, for example in increments of 128 megabytes.

**OutOfMemoryError: unable to create new native thread**

This error occurs when the operating system is unable to create new threads. This is due to the JVM Heap taking up the available RAM.

Big heaps take away from the space that can be allocated for the stack of a new thread

For 32bit Linux generally the maximum heap size of the JVM cannot be greater than 2GB. Windows systems will typically split the available physical memory 50:50 as Application and Kernel/System space, so please do not allocate an amount exceeding or approaching that split.

The size of the stack per thread can also contribute to this problem. The stack size can reduce the number of threads that can be created.

To fix this problem, you should reduce the size of your JVM Heap and also the size of the stack per thread.

The stack size can be changed with the following (example) parameter:

```
-Xss512k
```

Please refer to this guide as a reference for JVM tuning.

**OutOfMemoryError: GC overhead limit exceeded**

This error indicates that the JVM took too long to free up memory during its GC process. This error can be thrown from the Serial, Parallel or Concurrent collectors. It often means that the Xmx value is too high - you might consider lowering it. See Garbage Collector Performance Issues for more details. For more severe and persistent performance issues relating to GC, it is recommended to change to a parallel collector, and to ensure that Confluence has access to the memory demanded by its users.

The parallel collector will throw an OutOfMemoryError if too much time is being spent in garbage collection: if more than 98% of the total time is spent in garbage collection and less than 2% of the heap is recovered, an OutOfMemoryError will be thrown. This feature is designed to prevent applications from running for an extended period of time while making little or no progress because the heap is too small. If necessary, this feature can be disabled by adding the option `-XX:-UseGCOverheadLimit` to the command line.

This kind of OutOfMemoryError can be caused if user requests drown the available resources in the JVM. When this occurs, performance will degrade aggressively. This will eventually require a restart or the application may recover.

**OutOfMemoryError: Requested array size exceeds VM limit**

This is a rare error and indicates that Confluence attempted to allocate an array that is larger than the Java heap size. More details regarding this error can be found here.

This is due to a known limitation of the JVM as documented here. We have a bug lodged against this, to better handle this exception in Confluence.

### Setting the Memory Settings

How to set the heap or permanent generation memory depends on your distribution, platform, and how you start Confluence. Refer to Configuring System Properties.

- If you're starting Confluence from a Windows Service, make sure you add the properties through the registry settings.
- To verify if your settings have been picked up, check Displaying System Properties.
- Other factors such as system load and allocating too much memory to your JVM Heap can also cause OutOfMemory Errors. For more information, you can refer to the JIRA documentation on Causes of OutOfMemoryErrors.

#### RELATED TOPICS

**Editing the Windows Registry**

If you need to adjust memory settings and are using a Windows Service, you can adjust your memory settings using the instructions in this
You have two choices on how to set the memory settings.

**From the Command Line**

Run this command from the command line:

```
tomcat6 //US//Confluence --JvmMs 1024 --JvmMx 1024 ++JvmOptions=-"XX:MaxPermSize=256m"
```

**Edit the Registry**

1. Shut Confluence Service.
2. Go to Start >> Run >> Type in regedit. (On versions of Windows prior to Windows XP, please type regedit32 instead of regedit.)
3. In the registry editor, click to HKEY_LOCAL_MACHINE -> SOFTWARE -> Apache Software Foundation -> Procrun 2.0 -> Confluence -> Parameters -> Java. Here you will see an entry for JvmMx, which is the "maximum memory" setting. Choose an appropriate value based on Managing Application Server Memory Settings.

![Registry Editor](image1)

4. Double-click JvmMx to edit, change the Base to "Decimal" and adjust the value as necessary:

![Registry Editor](image2)

5. If setting the Perm Gen size, click Options and add -XX:MaxPermSize=256m:
If you want to add other JVM parameters, you can use the same method as when adding the permgen setting.

6. Restart Confluence Service.

Backup FAQ

This section contains solutions for common issues or queries associated with backing up the content within your Confluence site or installation.

The XML backup is known to be inefficient and prone to errors with larger instances. You can switch to an external backup process for a reliable and efficient solution.

View one of the following issues or queries for more information:

- Are there any scripts for backup creation and restore?
- Backup will not import
- Can Confluence be restored from a backup minus attachments?
- Can XML backups be deleted automatically?
- Does running a daily XML backup slow performance?
- How can I reduce the space taken up by automatic backups?
- How to Change the Version of a Space Backup
- How to Find Attachments in Attachments Folder
- Is it Possible to Store the Confluence Home Directory on a Network Share?

RELATED TOPICS

Site Backup and Restore

Are there any scripts for backup creation and restore?

Check out User Submitted Backup & Restore Scripts.

Backup will not import

See Troubleshooting failed XML site backups.

Can Confluence be restored from a backup minus attachments?

Yes, as long as the attachments have been backed up are the same time. Refer to Site Backup and Restore.

Can XML backups be deleted automatically?

Windows users must manually delete any backup files. Linux users can insert a nightly or weekly automation script or cron similar to the following:

```bash
ls -t <path to your backup dir>/* | tail +6 | xargs -i rm {}
```
Does running a daily XML backup slow performance?

The XML backup is known to be inefficient and prone to errors with larger instances. You can switch to an external backup process for large instances.

How can I reduce the space taken up by automatic backups?

Switch to a manual backup process according to the 'Backups For Large Instances' section of Site Backup and Restore, which will give you more control over disk usage.

How to Change the Version of a Space Backup

Confluence prevents the import of space backups which aren't from the same major version. The reason for this is that any schema change between the export and imported version of Confluence will cause the import to fail, leaving you with an incomplete import. Even worse, the failure can be database-dependent, so it may work fine on one particular database but your backup will fail to import later.

Do not import a modified space backup on a production server. Import the modified space backup on a test server, then export from the test server to create a pristine space backup for the new version.

To change the version of a space backup, do the following:

- extract the space backup ZIP file
- edit exportDescriptor.properties in a text editor
- change the buildNumber to the buildNumber of the Confluence version you wish to import into
- zip up the modified contents of the backup into a ZIP file again.

This will allow you to import a backup into a test instance of Confluence. After checking the imported space for errors, export it cleanly from the test server and import the fresh backup into your production server.

If your import fails on the test server due to Hibernate errors, this indicates a schema incompatibility and cannot be worked around. You will need to restore your entire site on an old version of Confluence, and export the space from there. See the last section of Restoring a space for details.

How to Find Attachments in Attachments Folder

Symptoms

Attachments are stored on filesystem but there isn't any attachment in the attachments folder.

Cause

The attachment naming scheme is numerical so as to avoid encoding problems with operating systems.

Resolution

You can look for the attachment detail (e.g file type, attachment name) from ATTACHMENTS table. As attachment is stored as this structure: <attachments>/pageID/attachment/attachmentVersion, you may want to run the following query to retrieve attachments of a page:

```
Select * from ATTACHMENTS where pageID='<PageID>'
```

You can determine the missing attachments by using the Missing Attachments Report.

Additional Information

<table>
<thead>
<tr>
<th>Severity</th>

</thead>
<tbody>
<tr>
<td>Regular Expression</td>
<td>attachment directory.* file system</td>
</tr>
<tr>
<td>Article ID</td>
<td>CONFKB151519277</td>
</tr>
</tbody>
</table>

Searching Confluence Knowledge Base

Is it Possible to Store the Confluence Home Directory on a Network Share?
Is it possible to house Confluence Home/Confluence on a NAS device instead of local drives?

It is possible to set up this configuration. To do so, specify the network location from 
<confluence-install>/confluence/WEB-INF/classes/confluence-init.properties. Atlassian does not suggest installing Confluence or hosting Confluence Home directory on NAS device because when a NAS or connection to NAS is down, Confluence cannot function correctly and you risk potential data corruption.

Configuration FAQ

This section contains solutions for common issues or queries associated with configuring Confluence.

This section focuses on providing instructions to customise Confluence's functionality and appearance by modifying its installation.

Running Tomcat on a Different Port

By default Confluence's Tomcat instance listens on port 8080 for connections, and port 8005 for the command to shut down.

If you see errors like:

```java
java.net.BindException: Address already in use:8080
```

in your logs, then you need to change the port number Confluence listens on (or you may be trying to start Confluence twice).

Confluence WAR/EAR distribution

Modify Tomcat conf/server.xml, change the ports used on the Server tag and HTTP Connector tag. If you don't know what this means, see the example in the Standalone configuration below.

Confluence Standalone 2.2 and newer

Edit conf/server.xml in your Confluence application directory, and change the ports on the Server tag and the Connector tag to unused ports on your system. The following example shows the relevant section of server.xml where they are changed to 8100 (Server) and 8180 (HTTP Connector). In this configuration you would access Confluence on the URL: http://localhost:8180/confluence.

```xml
<Server port="8100" shutdown="SHUTDOWN" debug="0">
  <Service name="Tomcat-Standalone">
    <Connector className="org.apache.coyote.tomcat4.CoyoteConnector" port="8180" minProcessors="5"
      maxProcessors="75" enableLookups="true" redirectPort="8444" acceptCount="10" debug="0"
      connectionTimeout="20000" useURIValidationHack="false" URIEncoding="UTF-8"/>
  </Service>
</Server>
```

Confluence prior to 2.2
You can change the port number by editing the file `<confluence install directory>/conf/server.xml.

Find the line:

```
<Connector className="org.apache.coyote.tomcat4.CoyoteConnector" port="8080" minProcessors="5" maxProcessors="75"
```

and change `8080` to the port you want to use.

If you are running two Tomcat instances, you'll also need to change the shutdown port in the line:

```
<Server port="8005" shutdown="SHUTDOWN" debug="0">
```

### Specifying the IP address to listen on

For versions 2.2 and later, edit `conf/server.xml` as described above, but add an `address` parameter. The [tomcat documentation](https://tomcat.apache.org/) is a useful reference here. To extend the example above, you can configure tomcat to listen only on the localhost interface with this configuration:

```
<Server port="8100" shutdown="SHUTDOWN" debug="0">
  <Service name="Tomcat-Standalone">
    <Connector className="org.apache.coyote.tomcat4.CoyoteConnector" port="8180" minProcessors="5" maxProcessors="75" address="127.0.0.1" enableLookups="true" redirectPort="8444" acceptCount="10" debug="0" connectionTimeout="20000" useURIVerification="false" URIEncoding="UTF-8"/>
  </Service>
</Server>
```

Why would you want to restrict it to access via localhost? If you're running Confluence behind a proxy server on the same host, this will make sure that users can't bypass the proxy and hit the application server directly.

If your machine also runs IIS, you might encounter a problem where IIS binds to the same port (for example, port 80) for all IP addresses on the machine. This means that you will not be able to run Confluence on another web or application server through that port until you address this IIS issue first. For more information, refer to this [Microsoft Knowledge Base article](https://support.microsoft.com/).

### Change default font, color, or spacing in Confluence

Beginning in Confluence 2.10, you can customise your space or instance using CSS from the User Interface. See [Styling Confluence with CSS](https://confluence.xxxx) here. For earlier versions, check the instructions here.

### How do I Change the Time of Daily Report Updates

You can configure Confluence to perform the daily updates at a time that is best suited to you or your organisational needs.

- **Time is derived from the Confluence server**
  - The time zone is taken from the server on which Confluence is running. To check the time according to the server, do the following:
    1. Go to the Confluence 'Administration Console'. To do this:
      * Open the 'Browse' menu and select 'Confluence Admin'. The 'Administration Console' view will open.
    2. Click 'System Information' in the left-hand panel and look at the 'System Time'.

Confluence uses [Quartz](https://quartz-scheduler.org/) for scheduling periodic jobs. To change the time of your daily report, you will need to edit the Quartz configuration.

- **To change the time of your daily reports**
1. Open the Quartz configuration file `schedulingSubsystemContext.xml` located under `confluence/WEB-INF/lib/confluence-x.x.x.jar`. Where x.x.x is your Confluence version number.

2. Find the following section of the file:

   ```xml
   <bean id="dailyReportTrigger" class="org.springframework.scheduling.quartz.CronTriggerBean">
     <property name="jobDetail">
       <ref bean="dailyReportJob"/>
     </property>
     <property name="cronExpression">
       <value>0 0 0 * * ?</value>
     </property>
   </bean>
   ``

3. The string `0 0 0 * * ?` sets up a Cron Trigger for the job to run at the zeroth second of the zeroth minute of the 0th hour (midnight), every day of every month, every day of the week.

4. Re-jar the file, either with a zip utility (change the title of .zip back to .jar) or a java command.

5. You can set a new time by editing this string. Note that the date and time format in this configuration file is in this order: Second minute hour day

   For example, to set the new time to twenty past ten PM, change the string to `0 20 22 * * ?`.
   For complete details on the formatting of the cron string, please see [http://www.opensymphony.com/quartz/api/org/quartz/CronTrigger.html](http://www.opensymphony.com/quartz/api/org/quartz/CronTrigger.html).

### How to audit Confluence - enabling user access logging

Often, for auditing purposes, administrators need to know who did what. Notifications are not ideally suited for this purpose. Instead, you can generate a basic log indicating which users are accessing which pages in Confluence. Application servers are able to log the requested URL, but they cannot determine the currently logged in user. This log is not currently formatted to be accessible to web log analysis tools such as AwStats as it lacks a host and get method, so must be viewed manually.

Similar to JIRA, Confluence has a built-in access logging mechanism, which shows the user and URL invoked. To enable it, you need to modify a couple of configuration files and restart Confluence.

#### Configuring the AccessLogFilter

There is a simple AccessLogFilter in Confluence than can be enabled via `confluence/WEB-INF/classes/log4j.properties` and `confluence/WEB-INF/web.xml`.

1. Uncomment these line in `log4j.properties`:

   ```
   log4j.category.com.atlassian.confluence.util.AccessLogFilter=INFO
   ```

2. Enable the filter in `web.xml` by removing the comments around these lines:

   ```xml
   <filter-mapping>
     <filter-name>AccessLogFilter</filter-name>
     <url-pattern>/display/*</url-pattern>
     <url-pattern>*.action</url-pattern>
   </filter-mapping>
   ``

   Notice that the *.action pattern is added optionally to log the actions of Confluence in addition to the page views. This combination of URL patterns will work for all URLs. You can further modify the pattern by adjusting the url-pattern field.
3. Restart Confluence

This will result in logging information being stored in the atlassian-confluence.log file in the confluence-home directory.

**Advanced configuration**

After this is working, you could redirect the access log to a different file by adding a new RollingFileAppender at the top of log4j.properties:

```java
log4j.appender.accesslog=org.apache.log4j.RollingFileAppender
log4j.appender.accesslog.Threshold=DEBUG
log4j.appender.accesslog.File=${catalina.home}/logs/atlassian-confluence-access.log
log4j.appender.accesslog.MaxFileSize=20480KB
log4j.appender.accesslog.MaxBackupIndex=5
log4j.appender.accesslog.layout=com.atlassian.confluence.util.PatternLayoutWithStackTrace
log4j.appender.accesslog.layout.ConversionPattern=%d %p [%c{4}] %M %m%n
```

Find this line:

```
#log4j.category.com.atlassian.confluence.util.AccessLogFilter=INFO
```

Change it to this:

```
log4j.category.com.atlassian.confluence.util.AccessLogFilter=INFO, accesslog
log4j.additivity.com.atlassian.confluence.util.AccessLogFilter=false
```

The web.xml url-pattern given above only matches page views (/display/*). You could change the url-pattern, or duplicate the entire filter-mapping to log access for different kinds of access (/admin/* for admin functions, /pages/* for edits and creates, etc. Note that /pages/editpage.action* doesn't work).

**What is logged**

The format produced is the following values separated by spaces:

1. Username or '-' if no user
2. URL
3. VM free memory at start of request (in KB)
4. Change in free memory after request is finished (in KB)
5. Time taken for request (in ms).
6. Remote address

Example:

```
2008-08-08 10:33:05,359 INFO [atlassian.confluence.util.AccessLogFilter] init AccessLogFilter initialized. Format is: <user> <url> <starting memory free (kb)> +- <difference in free mem (kb)> <query time (ms)> <remote address>
```

The above may be preceded by additional log4j-generated text, depending on the log4j pattern which is configured.

**Another option: Google Analytics**

Google Analytics can be easily integrated with Confluence for access tracking.

After signing up, copy the Javascript and paste it into the 'Before end of <body>' section of Administration, Custom HTML. This will put the Javascript on every page generated by Confluence.
This might not work correctly if your users are behind a firewall or authenticated proxy.

For more information on using Google Analytics with Confluence you may wish to refer to this blog post by David Simpson.

**RELATED TOPICS**

Working with Confluence Logs

**Share users and groups between Confluence and JIRA**

**How do I share users and groups between Confluence and JIRA?**

To save your having to enter users into both JIRA and Confluence, you can configure Confluence to use JIRA's user database.

Instructions on how to do this can be found [here](#).

**RELATED TOPICS**

- Revert from JIRA to internal user management (Confluence Docs 3.0)
- Delegate user management to use JIRA logins (Confluence Docs 3.0)

**How do I Modify the Frequency of Content Indexing**

Confluence Content Indexing frequency is handled using a cron job set in `schedulingSubsystemContext.xml`.

**Time is derived from the Confluence server**

The time zone is taken from the server on which Confluence is running. To check the time according to the server, do the following:

1. Go to the Confluence 'Administration Console'. To do this:
   - Open the 'Browse' menu and select 'Confluence Admin'. The 'Administration Console' view will open.
   - Click 'System Information' in the left-hand panel and look at the 'System Time'.

Confluence uses Quartz for scheduling periodic jobs. To change the time of your content indexing, you will need to edit the Quartz configuration.

To change the time of your content indexing
1. Open the Quartz configuration file schedulingSubsystemContext.xml located under confluence/WEB-INF/lib/confluence-x.x.x.jar. Where x.x.x is your Confluence version number.

   For Confluence earlier than 2.6, the index cron job is located in <install dir>/confluence/WEB-INF/classes/schedulingSubsystemContext.xml.

2. Find the following section of the file:

   ```xml
   <bean id="indexQueueFlushTrigger" class="org.springframework.scheduling.quartz.CronTriggerBean">
     <property name="jobDetail">
       <ref bean="indexQueueFlushJob"/>
     </property>
     <property name="cronExpression">
       <value>0 0/5 * * * ?</value>
     </property>
   </bean>
   ```

3. The string '0 0/5 * * ?' sets up a Cron Trigger for the job to run every 5 minutes.

4. Re-jar the file, either with a zip utility (change the title of .zip back to .jar) or a java command.

5. You can set a new time by editing this string. Note that the date and time format in this configuration file is in this order:
   - Second minute hour day

   For example, to set the new time to twenty past ten PM, change the string to '0 20 22 * * ?'.

For complete details on the formatting of the cron string, please see http://www.opensymphony.com/quartz/api/org/quartz/CronTrigger.html.

How do I change the default polling time for email in Confluence?

Modify the cronExpression property of the mailPollTrigger bean in schedulingSubsystemContext.xml file.

```xml
<property name="cronExpression">
  <value>0 0 12 * * ?</value>
</property>
```

In Confluence installation directory, this file is jarred in <confluence installation directory>/confluence/WEB-INF/lib/confluence-x.x.jar. Unzipping the file and placing it WEB-INF/classes folder will over ride the configuration from the jarred version.

For example, the expression below will fire at 12pm (noon) every day:

```xml
<property name="cronExpression">
  <value>0 0 12 * * ?</value>
</property>
```

You may also like to view an information on how to create Cron expressions to provide the ability to specify complex time combination.

http://quartz.sourceforge.net/javadoc/org/quartz/CronTrigger.html

How do I Configure an Automatic Refresh of the Recently Updated List

To have the dashboard refresh automatically:

1. Modify the Main Layout at Administration->Layouts->Main Layout.
2. Add in the `<META HTTP-EQUIV="REFRESH" CONTENT="5"> tag in the html header tag
3. This example will refresh the browser in every 5 seconds
How to revert from clustering to single node

If reverting from a Clustered configuration, one solution is to back up the data, install a new stand-alone, and restore the data. This is the recommended approach. An alternative is to set in confluence.cfg.xml:

```
<property name="confluence.cluster">false</property>
```

To check to see if clustering has been disabled, look in the logs after the xml during startup. In your catalina.out, you have:

```
INFO [KB:main] [KB:confluence.cluster.tangosol.TangosolClusterManager] startCluster Bringing up cluster service
```

This line won’t exist if you start it up with the config we gave above. That’s how to test it.

Adding a Site-Wide Banner

Confluence administrators can add a site-wide banner, i.e. a message or alert that will appear at the top of every page on your Confluence site.

![Screenshot: Example of a Site-Wide Banner](image)

To add a site-wide banner,

1. Go to the Confluence ‘Administration Console’. To do this:
   - Open the ‘Browse’ menu and select ‘Confluence Admin’. The ‘Administration Console’ view will open.
2. Click ‘Custom HTML’ in the ‘Look and Feel’ section of the left-hand panel.
3. Click ‘Edit’.
4. Add the following code to the ‘At end of the HEAD’ textbox.
   ```html
   <div style="background-color: yellow; border: 2px solid red; margin: 4px; padding: 2px; font-weight: bold; text-align: center;">
   Your important message...
   </div>
   ```
5. Click ‘Save’.

If you want the banner across the bottom of the page, you should add the code to the ‘At end of the BODY’ textbox instead.

Customising Look and Feel Overview

**Customise Confluence Page Exports**

Modify the style or content of the following page exports:

- Available Velocity Context Objects in Exporters
Available Velocity Context Objects in Exporters

Since the export functionality is not implemented as a WebWork action, it does not inherit the Velocity context of an action. It creates its own context and populates it with a separate list of components. All exporters will inherit this context.

<table>
<thead>
<tr>
<th>Velocity Reference</th>
<th>Description</th>
<th>Javadoc Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>$generalUtil</td>
<td>A GeneralUtil object with several useful methods, including URL encoding.</td>
<td>GeneralUtil</td>
</tr>
<tr>
<td>$textUtil</td>
<td>Common utilities for string manipulation.</td>
<td>TextUtil</td>
</tr>
<tr>
<td>$rendererBean</td>
<td>Mostly for internal use, but can also be used for manipulating page or space exports.</td>
<td>WikiExporter</td>
</tr>
<tr>
<td>$exportDate</td>
<td>A java.util.Date created when the export is actually performed.</td>
<td>Date</td>
</tr>
<tr>
<td>$exportContent</td>
<td>An ExportContext object which holds the context in which the export is performed, such as the user performing the export.</td>
<td>ExportContext</td>
</tr>
<tr>
<td>$dateFormat</td>
<td>Provides a date and time formatter suitable for the exporting user's locale and environment.</td>
<td>DateFormatter</td>
</tr>
<tr>
<td>$baseUrl</td>
<td>The base URL of the Confluence installation (http://&lt;server&gt;:&lt;port&gt;/contextPath).</td>
<td>String</td>
</tr>
</tbody>
</table>

Specific exporters may have additional context members. See their pages for details.

Customise Adobe PDF Exports

The PDF customisation procedures described on this page are only applicable to Confluence 2.10.4 and earlier versions. To customise PDF exports in Confluence 3.0, please use the procedure described in Editing the PDF Stylesheet.

Confluence pages can be output to PDF and some resulting PDF content can be modified. While page content itself is not open to customisation without major source-code modifications, this guide covers the easier task of modifying the plain text contained in page titles, headers and footers and page size.

Change in Confluence 2.6.0

The Velocity template files (files whose names end in .vm) were moved inside the main confluence-<version>.jar file with the release of Confluence 2.6.0 (i.e. $CONFLUENCE_INSTALL/confluence/WEB-INF/lib/confluence-2.6.jar in version 2.6). If you are unfamiliar with editing the contents of a jar file, you may find these instructions useful. Alternatively Java Servlet Technology allows you to use an unpacked version of the desired file in the WEB-INF/classes directory. Make sure you reproduce the exact directory (package) structure.

Change PDF page size

How to Change the page size
The default PDF page size is A4 (210mm x 297mm or 8.27in x 11.7in). Modify the file under your Confluence install directory:

```java
.../confluence/WEB-INF/classes/com/atlassian/confluence/importexport/common_fop.vm
```

To change the page size for PDF export, `page-width` and `page-height` parameters have to be edited in the above mentioned file. Locate the line

```xml
<fo:simple-page-master margin-right="2cm" margin-left="2cm" margin-bottom="1cm" margin-top="1cm"
page-width="21cm" page-height="29.7cm" master-name="all-pages">
```

and change the values for `page-width` and `page-height` as required.

This file is pretty self-explanatory. Change to the following values:

- `page-width="21.59cm"`
- `page-height="27.94cm"`

Optionally you can modify the margins. To give the page a half-inch margin all around:

- `margin-right="1.27cm"`
Landscape orientation

To change the default A4 +Portrait+ size to +Landscape+ follow the instructions below:

By default the page orientation for PDF export is set to "Portrait" with page-width="21cm" and page-height="29.7cm". To change the orientation to Landscape, swap the page-width and page-height measurement values as shown below:

```xml
<fo:simple-page-master margin-right="2cm" margin-left="2cm" margin-bottom="1cm" margin-top="1cm"
page-width="29.7cm" page-height="21cm" master-name="all-pages">
</fo:simple-page-master>
```

This will generate a PDF export with a Landscape orientation.

Editing PDF content

How to edit PDF content:

Confluence uses Apache FOP to write Confluence content to XSL-FO format, and uses Velocity macro files to render PDF headers, footers and page titles. For information on more content editing, study the XSL-FO examples.

Always stop Confluence before editing a Velocity macro file. Users who are stuck can obtain technical assistance by posting the modified Velocity file to the Confluence Developer Forum.

List Of PDF-Related Files

```plaintext
.../confluence/WEB-INF/classes/com/atlassian/confluence/importexport/common_header_fop.vm
.../confluence/WEB-INF/classes/com/atlassian/confluence/importexport/common_footer_fop.vm
.../confluence/WEB-INF/classes/com/atlassian/confluence/importexport/common_fop.vm
.../confluence/WEB-INF/classes/com/atlassian/confluence/pages/Page.pdfexport.vm
```

* The above example is for Unix-based systems, so Windows users should use back-slashes instead forward-slashes

  * An example Windows install directory is C:\confluence-2.2.9-std
  * An example Linux install directory is /opt/confluence-2.2.9/

Text

Inserting the example XSL-FO tag below into the relevant Velocity macro file will output a new line with This text is printed in plain text.

```xml
<fo:block text-align="left" font-family="$generalUtil.getDefaultFontFamily()" color="#0050B2">
  This text is printed
</fo:block>
```

Images

There are two steps involved in adding images to the header and the footer:

1. You need to modify common_fop.vm and adjust the margins, and sizes of the two regions (region-before and region-after) to fit in the image.

   ```xml
   <fo:region-before extent="1cm"/>
   <fo:region-after extent="1cm"/>
   ```

   In the example above, change the "1cm" value to allow yourself as much space as you need for your customization.

2. Insert the example XSL-FO tag below into the relevant Velocity macro file to embed the local image c:\images\operahouse.png into the PDF.

   You will need to convert the file location into a "file URI" before adding it the macro file. For Windows systems, the method is to replace all back-slashes in the local path with forward-slashes and prefix the result with file:// For UNIX-based systems prefix the path with file:// eg /tmp/image.png becomes file:///tmp/image.png

   There is a good explanation for this format in Windows here and if you're really keen (or having problems) a fuller description is here.
Modify Page Title

Modify page title for single page export
This title appears once on the first page of the PDF. An example title is

Demonstration Space : Timesheets
This page last changed on Nov 02, 2006 by Administrator

To modify the page title, go to your Confluence install directory and modify the Velocity macro file

...\confluence\WEB-INF\classes\com\atlassian\confluence\pages\Page.pdfexport.vm

If you want the modification of the page title to take into effect for space export, go to your Confluence install directory and modify the Velocity macro file

...\confluence\WEB-INF\classes\com\atlassian\confluence\spaces\Space.pdfexport.vm

The file contents are shown below

```
<fo:block text-align="left" font-family="$generalUtil.getDefaultFontFamily()" font-weight="bold" color="#0050B2">
$generalUtil.escapeXml($page.space.name) :
$rendererBean.nativeToAscii($generalUtil.escapeXml($page.title))
</fo:block>
<fo:leader leader-pattern="rule" leader-length="100%"/>
<fo:block color="grey" font-size="8pt" space-after.optimum="12pt">
This page last changed on $generalUtil.format($page.lastModificationDate) by
<fo:inline color="#0050B2">$!page.lastModifierName</fo:inline>.
</fo:block>
```

Explanation of the Velocity code from the above example

<table>
<thead>
<tr>
<th>Velocity Code</th>
<th>Prints</th>
</tr>
</thead>
<tbody>
<tr>
<td>$generalUtil.escapeXml($page.space.name)</td>
<td>Space Name</td>
</tr>
<tr>
<td>$rendererBean.nativeToAscii($generalUtil.escapeXml($page.title))</td>
<td>Page Name</td>
</tr>
</tbody>
</table>

Modify Page Headers for Space Export

How to modify page headers
By default, no page header is printed with PDF exports. To add one, go to your Confluence install directory and modify the Velocity macro file

...\confluence\WEB-INF\classes\com\atlassian\confluence\importexport\common_header_fop.vm

Example Header Modification

In between the two FO lines, add

```
<fo:block text-align="left" font-family="$generalUtil.getDefaultFontFamily()" color="#0050B2">
Custom Header
</fo:block>
```

Example Header Modification with Banner
Below is a sample common_header_fop.vm velocity template for header with Banner.

```xml
<fo:static-content flow-name="xsl-region-before">
  <fo:table width="100%" table-layout="fixed" font-family="serif" font-size="10pt">
    <fo:table-column column-width="14cm"/>
    <fo:table-column column-width="3cm"/>
    <fo:table-body>
      <fo:table-row>
        <fo:table-cell color="grey">
          <fo:block text-align="left" font-family="$generalUtil.getDefaultFontFamily()"
            color="#0050B2">
            <fo:external-graphic width="auto" height="auto" src="file:///c:/images/Top_Banner.jpg"/>
          </fo:block>
        </fo:table-cell>
        <fo:table-cell color="grey">
          This is your Customer Header
          <fo:block>
            This is your Customer Header
          </fo:block>
        </fo:table-cell>
      </fo:table-row>
    </fo:table-body>
  </fo:table>
</fo:static-content>
```

If you can't see your banner or image, update the value of `<fo:region-before extent="1cm"/>` in the common_fop.vm template to 4 or 5 cm according to the size of your banner or image. Please see CONF-9082 for a feature request on increasing the default value.

```xml
<fo:layout-master-set>
  <fo:simple-page-master margin-right="2cm" margin-left="2cm" margin-bottom="1cm" margin-top="1cm" page-width="21cm" page-height="29.7cm" master-name="all-pages">
    <fo:region-body margin-bottom="1.5cm" margin-top="1.5cm"/>
    <fo:region-before extent="4cm"/>
    <fo:region-after extent="1cm"/>
  </fo:simple-page-master>
</fo:layout-master-set>
```

**Modify Page Footers for Space Export**

How to modify page footer

Page footers appear on the bottom of every page. An example footer is:

```
Document generated by Confluence on Dec 11, 2006 09:35 Page 1
```

To modify the footer, go to your Confluence install directory and modify the Velocity macro file

```
...\confluence\WEB-INF\classes\com\atlassian\confluence\importexport\common_footer_fop.vm
```

**Example Footer Modification**

To produce this footer

```
Created on Dec 11, 2006 11:43
Copyright Altassian Software
```

Locate this line in `common_footer_fop.vm`

```
<fo:block>Document generated by Confluence on $generalUtil.formatDateTime($exportDate)</fo:block>
```

Replace it with the following Velocity code

```
<fo:block>Created on $generalUtil.formatDateTime($exportDate)</fo:block>
<fo:block>Copyright Altassian Software</fo:block>
```

To produce a footer with a ruler on top and page number on right and some copyright content on bottom then you can use the sample `common_footer_fop.vm` template below

```
<fo:static-content flow-name="xsl-region-after">
  <fo:block>
    <fo:leader leader-pattern="rule" leader-length="100%"/>
  </fo:block>
  <fo:table width="100%" table-layout="fixed" font-family="serif" font-size="10pt">
    <fo:table-column column-width="14cm"/>
    <fo:table-column column-width="3cm"/>
    <fo:table-body>
      <fo:table-row>
        <fo:table-cell color="grey">
          <fo:block>Document generated by Confluence on $dateFormatter.formatDateTime($exportDate)</fo:block>
          <fo:block>Created on $generalUtil.formatDateTime($exportDate)</fo:block>
          <fo:block>Copyright Altassian Software</fo:block>
        </fo:table-cell>
        <fo:table-cell color="grey">
          <fo:block text-align="end">Page <fo:page-number/></fo:block>
        </fo:table-cell>
      </fo:table-row>
    </fo:table-body>
  </fo:table>
</fo:static-content>
```

Sample PDF Footer Image:

```
Document generated by Confluence on Apr 24, 2007 14:00
Created on Apr 24, 2007 14:00
Copyright Altassian Software
```

**Exporter Velocity Context Additions**
**Velocity context objects specific to PDF exporting**

In addition to the objects available to all exporters, the PDF exporter has access to the following additional objects:

(When exporting entire spaces)

<table>
<thead>
<tr>
<th>Velocity Reference</th>
<th>Description</th>
<th>Javadoc Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>$space</td>
<td>The <code>Space</code> object for the space being exported.</td>
<td>Space</td>
</tr>
<tr>
<td>$contentTree</td>
<td>A <code>ContentTree</code> object representing the hierarchy of pages in the space to be exported.</td>
<td>ContentTree</td>
</tr>
</tbody>
</table>

(When exporting single pages)

<table>
<thead>
<tr>
<th>Velocity Reference</th>
<th>Description</th>
<th>Javadoc Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>$page</td>
<td>The <code>Page</code> object for the page being exported.</td>
<td>Page</td>
</tr>
</tbody>
</table>

**Export PDF in another Language**

**How to export in a different language**

Create PDF in another language

**Customise MS Word Exports**

**Overview**

Confluence exports a Confluence page as a Microsoft Word document by:

1. Generating the HTML rendering of a page from Confluence wiki markup
2. Overriding some Confluence page styles with MS Word styles using a CSS wrapper

The wrapper is generated using a Velocity macro to provide CSS style information specific to MS Word exports.

**Modifying Content**

Please do not attempt to modify the output without some experience in CSS and HTML markup. You may also need to review Velocity template language.

- W3Schools CSS Tutorial
- W3Schools HTML Tutorial
- Velocity Template Overview

Before modifying any styles, you should always take a backup of both any files you are modifying and your entire Confluence install directory. If you require assistance with your customisation attempt, you should post your modified files along with a technical description to our Confluence Developer Forum.

**Important Files**

The formatting is defined using the CSS styles in main Confluence stylesheet and overridden by any styles in the Word export wrapper.

**Main Stylesheet**

This file formats the default appearance of all Confluence content. Changes to this document will be shown when viewing a page from within Confluence, as well as in HTML or MS Word exports. You should avoid changing this document unless you wish a style to be changed throughout Confluence. The file is located under the Confluence install directory:

```named-strings
...\confluence\WEB-INF\classes\styles\site-css.vm
```

**Export Wrapper**

This file overrides the main Confluence stylesheet, so styles outlined in this file will be specific to MS Word exports. It set the font and style for body text, some macro and grids, and a default background colour. The file is located under the Confluence install directory:

```named-strings
...\confluence\pages\exportword.vm
```

**How To Modify Styles**
If the CSS tag already exists in the Word export wrapper, you can modify it directly. If the CSS tag is defined by the main stylesheet, copy it into the export wrapper as a new entry in the `<style>` element and update it there:

1. Identify its CSS tag in the main stylesheet. You may need to use trial and error to identify which cascading property is relevant
2. Transfer the tag into the Word export wrapper so that it overrides the main stylesheet
3. Modify the tag style in the wrapper

**Common Modifications**

You can easily set the body font or background colour in the export wrapper.

**Modify Body Font**

The wrapper sets the body font:

```html
body, p, td, table, tr,.bodytext,.stepfield {
  font-family: Verdana, arial, sans-serif;
}
```

**Modify Background Colour**

The wrapper sets the background colour:

```html
<body style="background-color: white; padding: 10px;">
  $page.title
  $renderedPageContent
</body>
```

**Editing the Footer**

- **'Powered by Atlassian Confluence'**
  Atlassian requires that the text 'Powered by Atlassian' be displayed in the footer on every page, as specified in the license agreement. Other than that, you can customise the footer text.

To change the footer text, follow the instructions in Modify Confluence Interface Text. You can specify additional configurations in `/confluence/decorators/includes/footer.vmd`.

If you need to revert to a former version, for example to restore the 'Powered By Atlassian Confluence' text, you can refer to the attached `footer` file.

**RELATED TOPICS**

- Modify Confluence Interface Text
- Customising Look and Feel Overview

**How do i completely remove the "Space Details" page from Confluence exports?**

1. Export to html file extension, and customize the layout from Administration->Layouts->Export Layouts->Space Export Layout
2. Export to PDF file extension, take a look at WEB-INF/classes/com/atlassian/confluence/spaces/Space.pdfexport.vm

**Where does Confluence store all its data?**

Attachments, extensions and configuration files are stored in the **Confluence Home Directory** that is configured when Confluence is first installed. All remaining data resides in the configured database.

See **Important Directories and Files** for more information.

**FAQ Home**

**Running Confluence Behind a Caching Proxy Server**

One major concern is Confluence’s ability to withstand a Slashdot, and someone told us that Atlassian had basically said
that Confluence could not handle the load of such an event/attack.

Ideally I would want to put a Squid cache directly in front of Confluence, set the default policy to cache content of normal pages for ~5 minutes (at least) and then pass-through more of the dynamic pages (like the editor & such).

This is, in fact, the case. We don't have any deployed Confluence sites that have the requirement of being Slashdot-proof, but this is probably one of those chicken-and-egg things.

The problem is not one of simple scaleability. We're currently working on "Confluence Massive", a clusterable Confluence that will scale to handle whatever load you feel like throwing at it. But if your aim is to protect the server against sudden, transient loads, throwing a cluster at the problem that will then spend 99% of its time not being utilised is probably a waste. Thus, the best solution is to have some kind of caching reverse-proxy that will divert load away from Confluence itself.

The main problem with the reverse-proxy solution is that every Confluence page is built dynamically for whichever user is currently accessing it. This affects obvious stuff like the "You are logged in as " notice, less obvious stuff like the "edit" and "attachments" links that appear or disappear based on whether the user has permission to perform the action on the other end of the link, and even less obvious stuff like wiki-links to spaces the user can't see, or in-page macros that output their content based on the user's identity.

To run Confluence behind a caching reverse-proxy, you'd need one of:

1. A proxy that understood the user's identity, or
2. A Confluence site that removed all the personalised content for cacheable pages.

If you had (1), you could tell the proxy to cache content only for anonymous users (since all anon content is the same, and to survive a slashdotting you only really have to worry about the sudden influx of non-logged-in users). That said, (1) is quite tricky, as it relies on the existence of some SSO mechanism that both Confluence and Squid can be hooked into. If such a mechanism existed, though, it'd be a really neat solution.

In the absence of SSO, you've got (2), which involves.

- Theme Confluence so that the 'view page' 'view blog post' and 'view mail' pages contain no personalised content: no profile link or user identity, and all links to other functions available whether the user has permission to access them or not.
- Ensure that all wiki pages on the server are meant to be visible to anonymous users
- Disable (or avoid the use of) macros that deliver different content based on user identity
- Introduce an interceptor into Confluence that would provide If-Modified-Since/Last-Modified conditional get support for wiki pages
- Configure Confluence so the site root URL points to a page, rather than the dashboard.
- Configure Squid to cache the 'view page' URLs (/display/* /pages/viewpage.action /pages/viewblogpost.action)

This is assuming that only the site root or a regular wiki page would ever be the victim of a direct slashdotting, but I figure this is a reasonable enough assumption to make.

With conditional get supported, you could have Squid configured to query the server to see if a page has changed, and just put in some kind of sensible defaults for the maximum time to cache any page (5 minutes or so would be fine, since pages could contain dynamic content), and the minimum gap between if-modified queries (15 seconds would easily prevent the server from being overloaded, while making sure that in regular use you wouldn't get many situations where you edited a page, but couldn't see your own changes).

I am trying to install Confluence but the demo-site.zip file is missing

The demo-site.zip is normally located in the WEB-INF/classes/com/atlassian/confluence/setup directory.

There are some cases where the extraction utility used to extract the Confluence installation file will recursively extract the contents of all zip files contained within the installation file. If the demo-site.zip file has been extracted, you will see an entities.xml file in this directory instead.

How do I Disable Automatic Mail Polling?

Disabling mail polling in Confluence will prevent Confluence from checking for new mail automatically, but mail retrieval will still work if a user triggers "Check for new mail" manually.

To disable automatic mail polling you would need to restart Confluence with the following parameter in your JVM's JAVA_OPTS:

-Dconfluence.disable.mailpolling=true

RELATED TOPICS
- How do I check which spaces have email accounts

Disabling Profile Pictures on the Recently Updated Dashboard
To prevent Profile Pictures from being displayed in the Recently Updated Dashboard:

1. Open your `confluence/decorators/global.vmd` file.
2. Edit the following line (change `true` to `false`)

   ```plaintext
   $helper.renderConfluenceMacro("{recently-updated-dashboard:dashboard|showProfilePic=true}"
   
   There is no need to stop or restart Confluence. The change should work on the next refresh of the page.

### How to Disable Profile Pictures from the Recently Updated Section of the Dashboard

**Description**

From Confluence 2.6, the recently updated section of the dashboard displays the profile pictures of the authors next to recently created pages and comments.

**Resolution**

To disable this, please follow the instructions outlined in [disabling profile pictures](disabling_profile_pictures).

### Additional Information

<table>
<thead>
<tr>
<th>Severity</th>
<th>Medium</th>
</tr>
</thead>
<tbody>
<tr>
<td>Regular Expression</td>
<td>`[Dd]isabl(e</td>
</tr>
<tr>
<td>Article ID</td>
<td>CONFKB132382971</td>
</tr>
</tbody>
</table>

Searching Confluence Knowledge Base

### Remove Version from Footer

1) Disable the footer content to be displayed

Remove/comment the following line in the main.vmd file which could also be accessed via Administration > Layouts > Main Layout (if you are using the "Default theme"):

```plaintext
#parse ("/decorators/includes/footer.vmd")
```

2) Modify the message rendered in the footer

This can be done in the `ConfluenceActionSupport.properties` file. See [Modifying Confluence Interface Text](modifying_confluence_interface_text) for a step-by-step guide. The following line is a mapping key to render the footer's message:

```plaintext
powered.by.atlassian.confluence
```

Searching Confluence Knowledge Base

### Configuring a MySQL Datasource in Apache Tomcat

Instructions on setting up a MySQL DataSource connection for Confluence Standalone or EAR/WAR.

- **autoReconnect=true** is required

  The Confluence database connection URL must have `autoReconnect=true` added to the end to prevent disconnection issues.

**Shut down Tomcat**

- Run `bin/shutdown.sh` or `bin/shutdown.bat` to bring Tomcat down while you are making these changes
Install the Drivers

- After unpacking the file you have downloaded, you'll find a file named something like mysql-connector-java-3.0.10-stable-bin.jar.
- Copy this file into the lib directory of your Tomcat installation. Be aware that this directory may be just lib for Tomcat version 6 and beyond.

Configure Tomcat

The configuration is different for Confluence 2.2 onwards due to an upgrade to Tomcat 5.5

For users of Confluence 2.2 and later

- If you are using the Standalone distribution, edit the conf/server.xml file in your Tomcat installation. Users running their own Tomcat instance must edit the xml file where they declared the Confluence Context descriptor.
- If editing conf/server.xml, find the following lines:

```
<Context path="" docBase="../confluence" debug="0" reloadable="true">
    <!-- Logger is deprecated in Tomcat 5.5. Logging configuration for Confluence is specified in confluence/WEB-INF/classes/log4j.properties -->
</Context>
```

- Within the Context tags, directly after the opening <Context.../> line, insert the DataSource Resource tag:

```
<Resource name="jdbc/confluence" auth="Container" type="javax.sql.DataSource" username="yourusername" password="yourpassword" driverClassName="com.mysql.jdbc.Driver" url="jdbc:mysql://localhost:3306/confluence?autoReconnect=true" maxActive="15" maxIdle="7" validationQuery="Select 1"/>
```

- **Replace the username and password parameters with the correct values for your database**
  
  - In the url parameter, replace the word 'confluence' with the name of the database your confluence data will be stored in.
  
  - If you plan to use non-latin characters, you will also need to add "&useUnicode=true&characterEncoding=utf8" on the end of the above URL. These options are not required for any database other than MySQL.

The configuration properties for Tomcat's standard data source resource factory (org.apache.tomcat.dbcp.dbcp.BasicDataSourceFactory) are as follows:

- driverClassName - Fully qualified Java class name of the JDBC driver to be used.
- maxActive - The maximum number of active instances that can be allocated from this pool at the same time.
- maxIdle - The maximum number of connections that can sit idle in this pool at the same time.
- maxWait - The maximum number of milliseconds that the pool will wait (when there are no available connections) for a connection to be returned before throwing an exception.
- password - Database password to be passed to our JDBC driver.
- url - Connection URL to be passed to our JDBC driver. (For backwards compatibility, the property driverName is also recognized.)
- user - Database username to be passed to our JDBC driver.
- validationQuery - SQL query that can be used by the pool to validate connections before they are returned to the application. If specified, this query MUST be an SQL SELECT statement that returns at least one row.

For users of Confluence 2.1.x and earlier

- Edit the conf/server.xml file in your Tomcat installation
- Find the following lines:

```
<Context path="" docBase="../confluence" debug="0" reloadable="true">
    <Logger className="org.apache.catalina.logger.FileLogger" prefix="atlassian-confluence." suffix=".log" timestamp="true"/>
</Context>
```

- Directly after the <Logger.../> line, (before the next <Context/> line), insert the following:
** You may want to choose different maxActive and maxIdle values: these are how many total database connections will be allowed at one time, and how many will be kept open even when there is no database activity

- Replace the username and password parameters with the correct values for your database
- In the url parameter, replace the word 'confluence' with the name of the database your confluence data will be stored in.
- If you plan to use non-latin characters, you will also need to add &useUnicode=true&characterEncoding=utf8 on the end of the above URL. These options are not required for any database other than MySQL.

Configure the Confluence web application

- Edit confluence/WEB-INF/web.xml in your confluence installation
- Go to the end of the file and just before </web-app>, insert the following:

```
<resource-ref>
  <description>Connection Pool</description>
  <res-ref-name>jdbc/confluence</res-ref-name>
  <res-type>javax.sql.Datasource</res-type>
  <res-auth>Container</res-auth>
</resource-ref>
```

Configure Confluence

- If you have not yet set up Confluence
  - Follow the steps in the Confluence Setup Guide
  - In the Database Setup section, choose the "Datasource Connection” option.
  - Set the JNDI name to java:comp/env/jdbc/confluence
  - Set the Database dialect to MySQL.
- If you are changing an existing Confluence installation over to using a Tomcat datasource
  - Find your ConfluenceHome directory (see: Confluence Home Directory if you don't know where it is).
  - Edit the confluence.cfg.xml file.
  - Delete any line that contains a property that begins with hibernate.
  - Insert the following at the start of the <properties> section.

```
<property name="hibernate.setup">true</property>
<property name="hibernate.dialect" value="net.sf.hibernate.dialect.MySQLDialect"/>
<property name="hibernate.connection.datasource" value="jdbc:mysql://localhost:3306/confluence?autoReconnect=true"/>
```

Restart Confluence
Run `bin/startup.sh` or `bin/startup.bat` to start Tomcat with the new settings.

F.A.Q.

I see "Can’t call commit when autocommit=true" during an upgrade of Confluence or otherwise.

Check out [http://jira.atlassian.com/browse/CONF-1710](http://jira.atlassian.com/browse/CONF-1710) This error can be fixed by adding: 
```
&relaxAutoCommit=true
```
to the end of your JDBC url.

Example:
```
jdbc:mysql://localhost/confdb?autoReconnect=true&relaxAutoCommit=true
```

This JDBC url can be found in your confluence.cfg.xml file located in your confluence home folder.

Installation FAQ

This section contains solutions for common issues encountered when installing and starting Confluence, including solutions to common queries about this process.

If necessary, review your logs by opening the Confluence install directory and checking the `/logs/catalina.out` and `/logs/catalina.out` files for errors you may encounter.

View one of the following issues or queries for more information:

- The Confluence window closes immediately when started
- How do I re-trigger the setup wizard
- Confluence starts but a problem prevents me from accessing the dashboard
- I receive a BUILD FAILED message when trying to create an EAR file in Confluence 2.6 or 2.7
- How much disk space does Confluence need?
- How Do I Make Confluence Accessible from the Root Context with a Tomcat EAR WAR configuration
- How To Run Confluence Standalone and Apache on Port 80 (Different IP Addresses)

The Confluence window closes immediately when started

An error is preventing Confluence from starting.

1. Open a command prompt. On Windows, do this by clicking on your Start menu, then click Run. In the Run box, type `cmd` and press OK
2. From the command prompt, go to your Confluence install directory
3. Go into the `bin` subdirectory
4. Run `startup.bat` and read the error message
5. Find a solution to the error below:
   - `java.lang.NoClassDefFoundError IntraHibernateAttachmentCopier`
   - `Exception in thread "main" java.lang.NoClassDefFoundError: ...`
   - `Error creating Confluence Home directory`
   - `JAVA_HOME environment variable is not defined correctly`
   - `Port 8080 is in use`
   - `Error creating bean with name 'scheduler'`
   - `Error registering bean with name 'fileSystemAttachmentDataDao'`

`java.lang.NoClassDefFoundError IntraHibernateAttachmentCopier`

If you are seeing "java.lang.NoClassDefFoundError: com/atlassian/confluence/pages/persistence/dao/hibernate/AbstractHibernateAttachmentDataDao$IntraHibernateAttachmentCopier", you have unzipped Confluence using a program that cannot handle long filenames. You must delete your install directory and go back to the point in the instructions that covers unzipping Confluence using a third-party unzip program.

`Exception in thread "main" java.lang.NoClassDefFoundError: ...`

If `http://localhost:8080` goes to an error page when you run Confluence, go to the install directory and find the `/logs/catalina.out`. If this file contains a single line error starting with "Exception in thread "main" java.lang.NoClassDefFoundError", your install path may contain spaces. The solution is to rename your install directory path so that there are no spaces, then restart Confluence.

`Error creating Confluence Home directory`

The confluence.home variable specified in confluence-init.properties cannot be created. To fix this, edit `/confluence/WEB-INF/classes/confluence-init.properties` and check the path specified exists. Make sure all the directory slashes use `/` and that the `#` has been removed. If you're stuck, try using `confluence.home=c:/confluence/data`

`JAVA_HOME environment variable is not defined correctly`

You have not installed the Java Development Kit, or not set the `%JAVA_HOME%` to the directory of the JDK. You should re-check your steps in Stage 2.
Port 8080 is in use
If you have another Tomcat running on the same machine, you must edit <INSTALL>/conf/server.xml and change both 8080 and 8005 to ports that do not conflict with your other Tomcat instance according to these instructions.

Error creating bean with name 'scheduler'
You will need to adjust your system time.

Error registering bean with name 'fileSystemAttachmentDataDao'
If you did not use one of the recommended unzipping tools, and happened to use for instance the one of the default Windows XP extractor, one of the classes required for starting up Confluence may not be located due to the lengthy file path. This is due to the reason that the default Windows tool silently fails to extract files with long names. We suggest you to use other tools such as WinZIP and 7zip and redo the deployment process.

Cause:
org.springframework.beans.factory.BeanDefinitionStoreException: Error registering bean with name 'fileSystemAttachmentDataDao' defined in class path resource [applicationContext.xml]: Class that bean class [com.atlassian.confluence.pages.persistence.dao.FileSystemAttachmentDataDao] depends on not found; nested exception is java.lang.NoClassDefFoundError:
com/atlassian/confluence/pages/persistence/dao/FileSystemAttachmentDataDao$FileSystemAttachmentNamingStrategy
at org.springframework.beans.factory.xml.DefaultXmlBeanDefinitionParser.parseBeanDefinition(DefaultXmlBeanDefinitionParser.java:366)
caused by: java.lang.NoClassDefFoundError:
com/atlassian/confluence/pages/persistence/dao/FileSystemAttachmentDataDao$FileSystemAttachmentNamingStrategy
at java.lang.Class.forName0(Native Method)

How do I re-trigger the setup wizard
To re-trigger the setup wizard:
1. Ensure the application server (for example, Apache Tomcat) running Confluence has been stopped.
2. Delete <confluence-home>/confluence.cfg.xml.
3. Re-start Confluence's application server and then Confluence.

Confluence starts but a problem prevents me from accessing the dashboard
Find a solution to one of these problems below:

- localhost:8080 times out
- localhost:8080 goes to the Tomcat start homepage
- Logins fail at the login screen

localhost:8080 times out
Check the server logs for errors. If you are running Confluence Standalone on Windows, error messages will be printed to the console window that opened when you ran startup.bat. On Unix systems, Confluence will log messages to logs/catalina.out.

localhost:8080 goes to the Tomcat start homepage
The CATALINA_HOME environment variable is set to another instance of Tomcat. You should run shutdown.sh, remove the CATALINA_HOME reference to the other Tomcat version, and run startup.sh again.

Logins fail at the login screen
If you try to login with the correct username and password but are always returned to the login screen without any error messages, and you are running Zone Alarm, please check that it is not blocking the Confluence server.

I receive a BUILD FAILED message when trying to create an EAR file in Confluence 2.6 or 2.7
When trying to create a EAR file, you may encounter with the following error:

BUILD FAILED

This is due to the build.xml file being incorrect for Confluence 2.6.x and 2.7.0. This problem will be fixed for future releases. However for these releases, please open the build.xml file and change the following two lines:

From:
To:

How much disk space does Confluence need?

For the recommended minimum amount of disk space, please see the 'Requirements' section in the Installation Guide.

Note that the actual disk space needed will depend significantly on the number of attachments (i.e. files which users attach to Confluence pages), and on the sizes of the attachments. You can calculate the hard drive requirements as you would with any standard file server.

RELATED TOPICS

Important Directories and Files (Confluence Docs 3.0)

FAQ Home

How Do I Make Confluence Accessible from the Root Context with a Tomcat EAR WAR configuration

Tomcat uses the ROOT.xml file to describe the root context. To make Confluence run at the Root, name the file that contains the context descriptor for Confluence ROOT.xml in the conf/Catalina/localhost/ directory. This is described in Installing the Confluence EAR-WAR Edition.

How To Run Confluence Standalone and Apache on Port 80 (Different IP Addresses)

To Configure Confluence to run on port 80 alongside another web service already on Port 80, you can add an "address" attribute to the connector element where address="<IP address on which Tomcat-Standalone is running >"

Change the server.xml file by adding the element:

```xml
<Connector className="org.apache.coyote.tomcat4.CoyoteConnector" address="192.168.1.1" port="9080" maxProcessors="75" enableLookups="true" redirectPort="8443" acceptCount="100" debug="0" connectionTimeout="20000" useURIValidationHack="false" disableUploadTimeout="true" />
```

Also change the hostname from localhost to the relevant host name, in the file above, on the same IP.

JIRA Integration FAQ

This section contains solutions for common issues or queries associated with Confluence’s JIRA integration features, such as its JIRA Issues Macro or JIRA User Management integration.

View one of the following issues or queries for more information:

- The JIRA Issues Macro behaves problematically
- The JIRA Issues Macro generates an error
- When setting up JIRA user management in Confluence, the Confluence login page loads but login fails
- When setting up JIRA user management in Confluence, the Confluence login page loads with an error

The JIRA Issues Macro behaves problematically

When the JIRA Issues Macro is used, one of the following problems may occur:

- Cannot access issues when JIRA uses HTTPS
- Issue icons are not displayed
**RELATED TOPICS**

**Cannot access issues when JIRA uses HTTPS**

Take a look at the Confluence Knowledge Base article on problems connecting to SSL services.

**Issue icons are not displayed**

Check that you are using the correct macro version for JIRA.

**RELATED TOPICS**

JIRA Issues Macro

Setting Up Trusted Communication between JIRA and Confluence

The JIRA Issues Macro generates an error

When the JIRA Issues Macro is used, one of the following errors is generated:

- The message 'Error Rendering Macro' is displayed, or either no or not all issues are displayed
- The message 'Error rendering macro: java.io.IOException: Could not download' is displayed
- The message 'Error rendering macro: java.io.IOException: Error on line -1: Premature end of file' is displayed

The message 'Error Rendering Macro' is displayed, or either no or not all issues are displayed

You may need to set up trusted communication between JIRA and Confluence. Please refer to the section on restricted viewing.

The message 'Error rendering macro: java.io.IOException: Could not download' is displayed

You may need to configure Confluence to acknowledge your proxy server before it is able to download the feed.

The message 'Error rendering macro: java.io.IOException: Error on line -1: Premature end of file' is displayed

Did you select an existing JIRA filter when you built the macro? If you did, your issues filter URL will end with .../12345/SearchRequest-12345.xml where 12345 is any number. You should retry using a new and unsaved filter.

**RELATED TOPICS**

JIRA Issues Macro

Setting Up Trusted Communication between JIRA and Confluence

The JIRA Issues Macro behaves problematically

When setting up JIRA user management in Confluence, the Confluence login page loads but login fails

When setting up JIRA user management in Confluence, the Confluence login page loads but login fails with one of the following errors:

- The Confluence login page loads but login fails with a 'Username and password are incorrect' error and the output log shows 'Access denied for user'
- The Confluence login page loads but login fails with a 'Username and password are incorrect' error and the output log shows 'Cannot create JDBC driver'
- I cannot get my JIRA integration to work, where can I get technical support?

The Confluence login page loads but login fails with a 'Username and password are incorrect' error and the output log shows 'Access denied for user'

This is caused by an incorrect database URL or login in the datasource.

The Confluence login page loads but login fails with a 'Username and password are incorrect' error and the output log shows 'Cannot create JDBC driver'

If your log outputs an error with "FATAL [user.provider.jdbc.JDBCCredentialsProvider] Could not list users. org.apache.commons.dbcp.SQLNestedException: Cannot create JDBC driver of class '' for connect URL 'null';", you are using the incorrect Tomcat format for specifying the Datasource resource. You should check your Tomcat version and use the alternative format.

I cannot get my JIRA integration to work, where can I get technical support?

See Requesting External User Management Support for information on logging a support request.
When setting up JIRA user management in Confluence, the Confluence login page loads with an error

When setting up JIRA user management in Confluence, the Confluence login page loads with one of the following errors:

- An error is encountered when JIRA is using Microsoft SQL Server
- The Confluence login page loads with a 'NullPointerException' system error
- The Confluence login page loads with 'HTTP Status 404' and the output log shows a 'java.lang.ClassNotFoundException' error for the driver, eg 'com.mysql.jdbc.Driver'

An error is encountered when JIRA is using Microsoft SQL Server

There is a known issue when JIRA is using Microsoft SQL Server and the schema name is 'jira'. Unfortunately in Confluence, you cannot define this schema name. Please refer to Knowledge Base article CSP-19533.

The Confluence login page loads with a 'NullPointerException' system error

If the page loads with 'System error' with cause 'java.lang.NullPointerException at com.atlassian.user.impl.osuser.OSUUserManager.getOpensymphonyUser(OSUUserManager.java:85)' and output logs shows 'user.provider.jdbc.BaseJDBCProvider] init Could not look up DataSource using JNDI location' error, either the Resource for the DataSource is not being loaded by the application server, or it is being loaded but the resource names do not match. Check the names first, so if '/confluence/WEB-INF/classes/osuser.xml' specifies a datasource named 'java:comp/env/jdbc/JiraDS', the datasource specified in server.xml or confluence.xml must be 'jdbc/JiraDS'.

The Confluence login page loads with 'HTTP Status 404' and the output log shows a 'java.lang.ClassNotFoundException' error for the driver, eg 'com.mysql.jdbc.Driver'

The database driver library is missing from your Confluence/application server installation. In your Confluence Standalone or Apache Tomcat installation, download the database jar to the common/lib directory.

LDAP FAQ

This section contains solutions for common issues or queries associated with LDAP integration in Confluence.

View one of the following issues or queries for more information:

- Are all users in LDAP visible in Confluence administration and can they be assigned permissions or to groups?
- Can we use LDAP and Confluence groups simultaneously, as a 'mixed mode', where some groups are kept in Confluence and others in LDAP?
- Confluence Domino LDAP FAQs
- Confluence integration with LDAP and Active Directory FAQs
- How are LDAP or Active Directory users counted toward my license limit?
- How can I assign an LDAP user a Confluence account?
- How can I enable LDAP?
- How does Confluence handle user deletions from LDAP? Is the user’s assignment to one or more groups still visible?
- I am having a problem with Confluence LDAP integration
- I enabled LDAP and some users are now returned twice under the user browser
- If a Confluence user had a lowercase username, but an LDAP user has the same username in UPPERCASE, does it matter which one I use?
- If a user already exists in Confluence and an LDAP user with the same username is added, which account’s password gets used?

Other Questions

For troubleshooting, please create a problem report. General enquiries should be posted to a support ticket.

RELATED TOPICS

LDAP User Management

Are all users in LDAP visible in Confluence administration and can they be assigned permissions or to groups?

All LDAP users with 'Can Use' permission can be viewed from the user browser, even if they have never logged in. When an LDAP user logs in for the first time, a Confluence user account is created automatically to store their information. You have read-only access to LDAP groups, and can add/remove Confluence internal groups to any user.

Can we use LDAP and Confluence groups simultaneously, as a 'mixed mode', where some groups are kept in Confluence and others in LDAP?

Yes.
Confluence 3.0 Documentation

Confluence Domino LDAP FAQs

Find an answer to one of these questions below:

- Why are individual users always shown as not belonging to any groups?

Why are individual users always shown as not belonging to any groups?

Domino servers allow user groups to be set as ‘mail-only’, ‘access control’ and ‘multi-purpose’. If the groups are set to ‘mail-only’, when Confluence queries the Domino LDAP server about a given user, Domino will return null. Groups that are created as ‘multi-purpose’ seem to work fine.

Confluence integration with LDAP and Active Directory FAQs

Find an answer to one of these questions below:

- Can Confluence make distinctions between security and distribution groups, or group types?
- Can group memberships be retrieved from multi-domain forests?
- Can Confluence support multiple Active Directory repositories?
- Can Confluence handle nested groups?

Can Confluence make distinctions between security and distribution groups, or group types?

No, Confluence has no group types. However, you can configure Confluence to only recognise some of these groups over others. For example, you can configure Confluence to only recognise distribution groups. This is done by adjusting the `groupSearchFilter` in your `atlassian-user.xml` file.

Can group memberships be retrieved from multi-domain forests?

Yes, you can do this by configuring multiple repositories: one for each domain. More instructions on how to do this can be found [here](#).

Can Confluence support multiple Active Directory repositories?

Yes.

Can Confluence handle nested groups?

No, each child group must be individually specified instead. You may wish to vote towards support for nested groups at [USER-101](#).

How are LDAP or Active Directory users counted toward my license limit?

Your user count is determined by the number of internal users plus the number of LDAP users who can potentially login. LDAP users that are a member of an LDAP group with 'Can Use' permission granted in Confluence can all potentially login, which means that all members of groups with this permission granted will be counted towards your license. To manage your license usage, only grant login permission to Active Directory groups where all members need accounts. You may like to setup a special confluence LDAP group if no combination of your existing groups is suitable.

How can I assign an LDAP user a Confluence account?

LDAP groups or users granted 'Can Use' permission under 'Global Permissions' can login to Confluence.

How can I enable LDAP?

See [Add LDAP Integration](#).

How does Confluence handle user deletions from LDAP? Is the user's assignment to one or more groups still visible?

Users are not deleted from Confluence, but their logins are disabled within one hour as they expire in the cache. Only non-LDAP groups are retained. Refer to the [overview](#) for more detail.

I am having a problem with Confluence LDAP integration

Find a solution to one of these problems below:

- I just added LDAP integration, why can't I login using my original account?
- Why do my LDAP users sees 'Not Permitted' screens when they login?
- Confluence fails to start with error 'Error creating bean with name 'userManager' defined in class path resource
Editing a user under Administration -> Manage Users throws an error 'org.apache.velocity.exception.MethodInvocationException'

After setting up LDAP, I cannot see LDAP users or groups from the Confluence user or group browser

I cannot see an LDAP/AD group in Confluence

I cannot get my LDAP to work, where can I get technical support?

I just added LDAP integration, why can't I login using my original account?

If there is an LDAP user with the same username as your administrator account, you must now use their password to login. LDAP logins override internal logins.

Why do my LDAP users sees 'Not Permitted' screens when they login?

To login, the user must be a member of one or more groups that have been granted 'Can Use' permission from the Administration -> Global Permissions -> Group Permissions.

Confluence fails to start with error 'Error creating bean with name 'userManager' defined in class path resource [atlassianUserContext.xml]'

Your atlassian.xml file may contain filters with characters that must be escaped from XML. Check here for details.

Editing a user under Administration -> Manage Users throws an error 'org.apache.velocity.exception.MethodInvocationException'

If you see an error:

You should open \confluence\WEB-INF\classes\atlassian-user.xml and check that your Hibernate Repository is not wrapped in a comment tag (<!-- and -->). The line to uncomment is:

```xml
<hibernate name="Hibernate Repository" key="hibernateRepository" description="Hibernate Repository" />
```

After setting up LDAP, I cannot see LDAP users or groups from the Confluence user or group browser

Are your users or groups located in subtrees beneath the directory returned by the search filter? If so, you may need to add <usersearchalldepths>TRUE</usersearchalldepths> or <groupsearchalldepths>TRUE</groupsearchalldepths> to your atlassian-user.xml See Map LDAP Users and Groups for details.

I cannot see an LDAP/AD group in Confluence

Is the group in a subtree? If so, you will need to edit atlassian-user.xml and add a groupSearchAllDepths=true parameter to the LDAP repository to set Confluence to search subtrees of the base group namespace. See Map LDAP Users and Groups for details.

I cannot get my LDAP to work, where can I get technical support?

See Requesting External User Management Support for information on logging a support request.

I enabled LDAP and some users are now returned twice under the user browser

When LDAP is enabled, it is normal for the user browser to return two copies of users who have both LDAP and internal users accounts. If you are interested in a fix for this, please vote towards "User browser shows duplicate accounts when a user exists both locally and in LDAP".

If a Confluence user had a lowercase username, but an LDAP user has the same username in UPPERCASE, does it matter which one I use?

As mentioned in another FAQ, LDAP login has priority over the confluence login. However, only the password is taken into account here. You can log in with either the lowercase or UPPERCASE username.

If a user already exists in Confluence and an LDAP user with the same username is added, which account’s password gets used?

The LDAP login has priority over the Confluence login. If LDAP 'Can Use' permission is removed or the user is deleted, the Confluence login will still work.

Mail Archiving FAQ

This section contains solutions for common issues or queries associated with Confluence's Mail Archiving feature that was introduced in Confluence 1.3.

View one of the following issues or queries for more information:
Can Confluence replace my regular mail client?

No.

Confluence's mail archive is designed to supplement the way you currently handle email, not to replace it. This is why Confluence deliberately does not come with features common in email clients. For example, you can not mark emails as read or unread, you can not reply to emails from within Confluence, and so on.

How do I get mail into Confluence?

All mail messages belong to a particular space.

From the space administration screen, space administrators can:

- Configure Confluence to poll a POP mailbox for incoming mail
  1. Go to Space Admin
  2. Choose "Mail Accounts"
  3. Add Pop Account

- Import mail from an mbox-format mail file

Confluence will delete mail from a POP box as it reads it. Do not point Confluence to an account unless you are happy with it removing all the mail you have stored there.

How do I use the mail archive?

Some suggested scenarios include:

Project-related conversations

Say you are using a Confluence space to organise a project. The project lead and the customer have a long conversation (via email) clarifying the project's goals and requirements. Rather than have that conversation lost in their individual mailboxes, if they CC'ed their mail to a POP box being monitored by Confluence, all that information will be archived alongside the rest of the project's documentation.

Customer Support Tracking

All incoming and outgoing sales and support email is diverted (at the mail-server) to be read by Confluence. Staff can then use Confluence's features to find all previous communications with particular customers.

And?

Of course, the real fun will come from seeing how this feature can be put to other uses.

Okay, I've imported the mail, but where is it?

Because of the typically overwhelming volume of email, especially compared to the more sedate pace of wiki updates, we do not notify you of recently arrived mail in the same places we notify you of changed Confluence content.

Mail will not appear in the recent changes list on the dashboard or space summary pages. Similarly, mail will not appear by default in search results.

You can view mail...

1. In order of arrival from the Mail Archive section, found under the Content tab of the Space Summary screen.
   a. 'Browse' Dropdown menu > Mail
2. You can also explicitly select Mail (or All Content) in the search page to include mail in your search results
3. Use the Recently Updated Macro to display, for example, the latest archive of mail on any Confluence Page
New User FAQ

This section contains solutions for common issues or queries encountered by new Confluence users.

View one of the following issues or queries for more information:

- Can I use CamelCaseLinks like they do on WardsWiki?
- Can Users Edit Individual Sections Within a Page?
- How does Confluence differ from a wiki?

Can I use CamelCaseLinks like they do on WardsWiki?

Yes you can. Camelcasing is not enabled by default but a site administrator can easily enable it from the administration screens.

See Enabling CamelCase Linking.

Can Users Edit Individual Sections Within a Page?

Some wiki software allows the editing of sections within a page (sectional editing). This functionality is currently not available in Confluence, but we are looking to include it in a future release. This issue is being tracked on the Confluence JIRA project: CONF-5913.

In the meantime, for pages that are getting long enough to be hard to edit in a single block, you can get an approximation of sectional editing by using the {include} macro. For example:

```markdown
h3. [Section One] 
{include:Section One}

h3. [Section Two] 
{include:Section Two}
```

The links to the edit pages can be simplified by using the {link-to:page edit} macro available in David Peterson's Linking Plugin.

Technical Stuff

The problem lies in the complexity of Confluence's wiki markup. We made a couple of proof-of-concept implementations of sectional editing as part of our ShipIt Day program, and while it's quite easy to come up with a solution that works with 90% of pages, there are a lot of edge-cases where it's actually quite hard to determine precisely where a given section starts and finishes.

Next time we perform a significant overhaul of our wiki markup processing engine, we'll be looking specifically to add functionality that will make sectional editing work properly.

How does Confluence differ from a wiki?

Essentially, Confluence is a wiki. Our aim was to build an application that was built to the requirements of an enterprise knowledge management system, without losing the essential, powerful simplicity of the wiki in the process.

From the wiki, we took the following lessons:

- It should be easy for anyone to create and edit pages
- It should be easy for anyone to link pages together
- It should be easy to see what has changed recently
- The site should be searchable
- Users should have the tools to organise and group pages without having any particular structure imposed upon them

On top of that, we added professional features, such as the partitioning of content into separately managed spaces, user- and group-based access control, automated refactoring, PDF exporting, searchable attachments, a comprehensive remote API, easy installation and a professional and easy-to-use presentation; all wrapped up in Atlassian's "Legendary Service".
RSS Feeds FAQ

This section contains solutions for common issues or queries associated with RSS Feeds and the RSS Feed Macro.

View one of the following issues or queries for more information:

- Create an RSS feed for mail from only specified mail accounts
- How do I fix a "Could not download (Feed URL) - Connection timed out (errno238)" error?
- How do I fix a "Could not retrieve (Feed URL) - Not Permitted" error?
- How do I fix an "Error formatting 'macro rss java.lang.NullPointerException" error?
- How do I fix an "Unable to retrieve (Feed URL) - Connection refused - connect" error?
- How do I force authentication for public feeds?
- Is it possible to delete a feed?
- I want to remove RSS Feeds completely

Create an RSS feed for mail from only specified mail accounts

This is not possible, but you can vote towards tagging incoming mail with labels on arrival. Once tagged, feeds could monitor all new mail with that label.

How do I fix a "Could not download (Feed URL) - Connection timed out (errno238)" error?

The feed source may be offline, or the firewall may be blocking access either between the Confluence server any your computer. Confirm that you can access the feed URL from your browser. If it cannot, your firewall settings may be blocking access to Confluence. For example, your server may be configured to block outgoing requests.

How do I fix a "Could not retrieve (Feed URL) - Not Permitted" error?

You must append a valid login to Private Feeds as described in the Usage section of the RSS Feed Macro.

How do I fix an "Error formatting 'macro rss java.lang.NullPointerException" error?

The link is not a valid feed, so check your URL. If stuck, you can recreate internal Confluence feeds Using the RSS Feed Builder.

How do I fix an "Unable to retrieve (Feed URL) - Connection refused - connect" error?

The URL is invalid. If the link appears correct, confirm that you can access Confluence. Paste the feed into a third-party RSS feed reader and confirm that it can access it. If it cannot, your firewall settings may be blocking access to Confluence. For example, your server may be configured to block outgoing requests.

How do I force authentication for public feeds?

With anonymous access enabled, you can force user authentication when creating the feed by checking 'Authorised'. If anonymous access is disabled, all feeds will require user authentication.

Is it possible to delete a feed?

No, because RSS feeds are based on the view permissions for pages and spaces. RSS is an extension of normal page viewing functionality, so if you can view a page, you can receive an RSS feed for it. The only way to remove an RSS feed is to prevent all access to a page for that user, so that no content will be delivered.

I want to remove RSS Feeds completely

While Confluence does not have this functionality, there is a work around to remove RSS feeds completely. Refer to How do I Disable RSS Feeds?

Upgrade FAQ
This section contains solutions for common issues and queries encountered when upgrading Confluence.

View one of the following issues or queries for more information:

- I cannot find the "Rich Text" editor. Is the editor part of Confluence 1.4.3?
- Server ID FAQ
- Upgrade My Trial To A Commercial Version

I cannot find the "Rich Text" editor. Is the editor part of Confluence 1.4.3?

The Rich Text Editor (aka WYSIWYG editor) is available in Confluence 2.0 and upwards. Rich Text editing is enabled by default.

If you wish to upgrade your Confluence installation, instructions can be found here.

**RELATED TOPICS**

- [Enabling Rich Text Editing Option](https://confluence-docs.org) (Confluence Docs 3.0)
- [Making Rich Text Editing default](https://confluence-docs.org) (Confluence Docs 3.0)

**Server ID FAQ**

**What causes this Server ID to be generated? Is it tied to the hardware, OS, or Confluence instance?**

The Server ID:

- is generated when you install Confluence for the first time
- exists for the life of the Confluence instance
- survives an upgrade
- is held in the database
- is not bound to a specific licence
- is the same for all servers in a cluster.

**What's the policy on re-associating licenses with server IDs?**

There's no need to do this. Once you have a Server ID associated to a license, you can leave it as is.

**What happens when I need to reinstall (quickly) on a different system?**

Because the server ID is held in the database, it travels with the instance when the database or XML backup is restored on the new system. You need not generate a new Server ID for your new system.

**What do I do when the license screen from my.atlassian.com is asking for my Server ID?**

The Server ID is located on the license screen. If you have only a License ID, you may bypass the requirement to enter a Server ID - just look for the link from my.atlassian.com on my.atlassian.com after choosing "associate server ID." Check [Unable to Find Server ID for Confluence 2.5.4 or Before](https://confluence-docs.org) for further info.

<tbody>
<tr>
<td>Article ID</td>
<td>CONFKB151519275</td>
</tr>
</tbody>
</table>

Searching Confluence Knowledge Base

**Upgrade My Trial To A Commercial Version**

First, you will need to purchase Confluence to receive your commercial license key. If you already have a free 30 day evaluation then you can easily convert this to the commercial version, or setup your commercial instance on another system and transfer your trial data across.

**Upgrade A Trial To The Commercial Version**

If you wish to change your trial into a commercial version while keeping the same hardware, login in as a Confluence administrator and past

1214
in your commercial license key under the Administrator > License Details screen. The conversion to a commercial version is instantaneous and can be done regardless of whether your evaluation period has expired or is still ongoing.

**Migrate Your Trial Data To A Server**

If you installed your Confluence trial on a PC but wish to host your commercial version on another system, such as a server managed by your IT department, you can transfer the trial data across. Begin by creating an XML backup on the trial PC, then install Confluence on the commercial server. During installation, you will be presented with the Confluence Setup Wizard. The wizard gives you the opportunity to insert your commercial license key and also to import an XML backup. If you import the XML backup from your trial, your commercial instance will be setup already containing all your trial wiki content and any internal users.

**Usage FAQ**

This section contains solutions for common issues or queries about the everyday use of Confluence.

View one of the following issues or queries for more information:

- Add many files to a page at once
- Create a page by passing parameters to a template
- How do I obtain content that hasn't been modified in a certain period of time
- How to Add a Quick Search for Firefox
- How to Find Pages with no Label
- How to Make Confluence Open a New Tab when Clicking on the Attachments Link
- How to Reset a Custom Layout
- Redirect to a specific page (home page) within the site after logging in
- Setup email notifications of page updates

**Add many files to a page at once**

Confluence pages and attachments can be mounted as a network drive, and files can be dragged and dropped into Confluence using the WebDav plugin. Alternatively, users who do not wish to use WebDav can write a custom script to attach all PDF files in a directory to a Confluence page using the addAttachment function in the Remote API. This script can be adapted from one of the Remote API script examples.

**Create a page by passing parameters to a template**

Confluence supports populating wiki content through templates. Check out Page Templates if you would like to create a new page by filling in a graphical, form-based template. If you have an existing page and would like to pass text as parameters to a macro that fills in the blanks in a template, create the template as a User Macro and call it from inside your Confluence page.

**How do I obtain content that hasn't been modified in a certain period of time**

This can be achieved by running the following SQL query on your Confluence database.

```
select * from content as c, spaces as s where c.spaceid = s.spaceid and s.spacename='INSERT SPACE NAME HERE' and c.LASTMODDATE < 'INSERT DATE HERE';
```

**How to Add a Quick Search for Firefox**

**Description**

To add a quick search term into Firefox's address bar, add the following link to your bookmarks:

```
http://confluence.atlassian.com/dosearchsite.action?quickSearch=true&searchQuery.queryString=%s
```

Make a keyword for it, and you can search a confluence instance using the keyword, a space and then the search term. For example, if you use the keyword cac with the above link, you can search confluence using:

```
cac searchterm
```

## How to Make Confluence Open a New Tab when Clicking on the Attachments Link

Modifying the template file in confluence-attachments-plugin-x.x.jar (in this case, I try on confluence-attachments-plugin-2.10.jar). Please edit attachmentsmacro.vm file. This file is located in confluence-attachments-plugin-2.10.jar file. Extract this file by using the [Editing files within jar archives guide] guide.

If you are able to extract it successfully, you can locate to attachmentsmacro.vm file and find the following lines:

```html
<\td><a name="$generalUtil.urlEncode($page.title)-attachment-$generalUtil.urlEncode($attachment.fileName)"
>
$\parse="/\pages\includes\attachment_icon.vm"
<a href="$req.contextPath$attachment.downloadPathWithoutVersion">$attachment.fileName</a></\td>
```

and change the above code to be:

```html
<\td><a name="$generalUtil.urlEncode($page.title)-attachment-$generalUtil.urlEncode($attachment.fileName)"
>
$\parse="/\pages\includes\attachment_icon.vm"
\a target="_blank" href="$req.contextPath$attachment.downloadPathWithoutVersion">$attachment.fileName</a></\td>
```

After making changes, please repack the file by following the steps [here].

### Additional Information

**Severity** | Medium

## How to Reset a Custom Layout

If the layout has changed so extensively as to not be visible, you can browse to the URL directly:

```
http://<confluence base url>/admin/resetdecorator.action?decoratorName=decorators/main.vmd
```

Substitute the base URL and the appropriate vmd file.

### Redirect to a specific page (home page) within the site after logging in

As a user, you can set the home page to which you are sent after logging in.

To set your home page as a user:

1. View your profile via the profile link on the top right
2. Click the Edit My Profile on the right
3. Set Site Homepage to your desired home page

For instructions on configuring this feature at the administrator level, see Redirect users to a site-wide home page after a successful login.
**RELATED TOPICS**

Redirect users to a site-wide home page after a successful login

**Setup email notifications of page updates**

Confluence sends notifications of changes to spaces or pages to users who are watching pages. Users choose to watch pages or spaces, an administrator does not force notifications upon them.

There is one way to automatically have users watch a given page or news item. The Autowatch Plugin can be set up to have anyone who contributes to a space watch the content they have contributed to. Eg. if they comment on a page, they will be set to watch that page for further updates. This should be used with care.

To set up a watch on a specific page or space as a user, see:

- Watching a Page
- Watching a Space

For instructions on configuring administrator-level email notifications, see Configuring Confluence to send email notifications.

Working with Pages Overview

Pages are the primary means of storing and sharing information in Confluence. Pages are contained within spaces.

- Use spaces to organise your wiki content into your primary logical groups. For example, you could have a space per team, per product or per department.
- Use pages to organise your content into lower-level groups. For example, you could have a page for a particular team activity, or for a feature in a product, or for a chapter in a book. Then add more child pages to contain lower-level details if necessary.

Things you can do with pages in Confluence:

- Create a new page from anywhere within the site.
- Write content in a simple markup language or using the Rich Text editor.
- Edit and rename a page.
- Organise pages hierarchically via parent-child relationships.
- Move pages while editing a page or while viewing the space’s Tree view.
- Navigate within and between spaces through flexible linking.
- Collaborate via comments on a page.
- Control access through page security restrictions.
- Monitor page updates and other activity through page notifications.
- View page history and link to older versions.
- Search page content, including attachments.
- Export pages to PDF, WORD, HTML or XML.
- Email page content.

E-mailing a Page

In Confluence, you can easily e-mail a Confluence page to recipients of your choice.

To e-mail a Confluence page,

1. Go to the 'Information' view for the page. To do this:
   - Go to a page in the space, open the 'Tools' menu and select 'Info'. The 'Information' view will open.
2. In the first box displayed, click the 'E-mail' link (beside 'Operations').
   - This may not be visible if this feature is turned off — see note at the bottom of this page.
3. This will display a box for you to enter the e-mail details (see screenshot below).
   - **Recipients: E-mail address(es)** — To send the email to someone who isn’t a Confluence user, type their email address. You can type multiple addresses, separated by commas.
   - **Recipients: Confluence Group(s)** — Type the name of the Confluence group (or groups, separated by commas); or click this icon to select a group from the list.
   - **Recipients: Confluence User(s)** — Type the name of the Confluence user (or users, separated by commas); or click this icon to select a user from the list.
   - **Subject** — (Optional) Type the email's subject line.
   - **Notes** — (Optional) Type the text (if any) which you want to appear at the top of the email's body. This text will appear before the contents of the Confluence page.
   - **Format** — Choose whether to send the email in 'Text' or 'HTML' format.
4. Click the 'Next' button.
5. A preview of your email will be displayed.
   - To change the Recipients, Subject, Notes or Format, click the 'Edit' button (at the right of the page).
   - To send the email, click 'Send' button (at the bottom of the page).
Optional Feature
This feature is disabled by default, to prevent it from being used as a tool for spamming or harassment. If you want to enable the e-mailing of pages, please ask your Confluence administrator.

Instructions for enabling this feature can be found here: Enabling the 'Mail Page' plugin

---

Confluence 3.0 Documentation

**Working with Page Families**

In Confluence, you can organise pages into a hierarchy of parent and child pages. Pages in such a hierarchy are called a page family.

Page families are a simple but effective way of categorising content. Confluence makes navigation of your site easier by providing links forward and backwards through the page hierarchy.

A parent page is at the topmost level of that hierarchy. Subpages are called child pages or children.

Read more about page families.

Things you can do with page families in Confluence:

- View a page's family
- View a page's location within a space
- View the hierarchy of all pages within a space
- View the children of a page
- Create a child page
- Move and re-order pages while editing a page or while viewing the space's Tree view.
- Order the pages in a page family alphabetically.
- Change the parent of a page

**Setting a Page Family to Alphabetical Order**

You can choose to display your Confluence pages in alphabetical or manual order. This page tells you how to set the pages within a family to alphabetical order.

On this page:

- About the Sequential Order of Pages
- Setting Page Order to Alphabetical
About the Sequential Order of Pages

Confluence allows you to present your pages in any order (sequence) you choose. The position of a page is reflected in the following places:

- The Tree tab on the space's 'Pages' view
- Space exports to PDF, HTML and XML
- The children of a page
- The pagetree macro
- The children macro

Alphabetical versus Manual Order

By default, Confluence will present your pages in alphabetical order. When you move a page to a different position, the order becomes manual for the affected page family.

When ordering pages alphabetically, Confluence actually applies a more sophisticated 'natural' order rather than a straight alphabetical order. The natural order handles numeric values correctly when doing string comparisons.

Now let's consider what happens when you add a page to a page family, by creating a new page or by moving or copying a page into the family:

- If the page family's order is alphabetical, the new page will appear in alphabetical order too.
- If the page family's order is manual, the new page will appear at the bottom of the list of pages in the family.

Changing the Page Order

You can change the order of the pages by moving pages within the page family — simply move the page to its new position while editing the page (see Moving a Page) or while viewing pages in the space's 'Tree' view (see Moving Pages within a Space).

You can also change the order of a page-family from manual to alphabetical (see the 'Setting Page Order to Alphabetical' section on Setting a Page Family to Alphabetical Order).

Setting Page Order to Alphabetical

If the pages in a page family have been ordered manually, you can reset the page order to alphabetical as described below.

A page family is a set of pages under a single parent page. In this section, when we say 'page family' we mean the immediate children of the parent page, not including the grand-children.

The screenshot below shows a family of pages in non-alphabetical order under the parent 'Sample Page'. Notice the A icon next to the parent 'Sample Page', giving you the option to order the pages alphabetically.

Screenshot: A family of pages in non-alphabetical order with 'Sort Alphabetically' icon

To set a page family to alphabetical order,
1. Go to the ‘Space Pages’ view for the current space. To do this:
   
   - Go to a page in the space, open the ‘Browse’ menu and select ‘Pages’. The ‘Space Pages’ view will open.
2. Go to the ‘Tree’ tab. The tree view will open, as shown in the screenshot above.
3. Expand the branches of the tree to find the page family you want.
4. If the page family is in non-alphabetical (manual) order, the ‘Sort Alphabetically’ icon \(\text{A}\) will appear next to the parent page as shown in the screenshot above. Click the icon.
5. The child pages will shuffle into alphabetical order and the icon will change to the ‘Undo Sorting’ icon \(\text{B}\) as shown in the screenshot below.

   (Note: Only the immediate children of the parent page will be affected. The grand-children will not be re-ordered. (If you want to re-order the grand-children, you need to click the ‘Sort Alphabetically’ icon next to the parent of those pages i.e. re-ordering happens for one node at a time.)

Screenshot: A family of pages in alphabetical order with ‘Undo Sorting’ icon

List Pages - Tree View

<table>
<thead>
<tr>

<th>News</th>
<th>Labels</th>
<th>Attachments</th>
<th>Bookmarks</th>
<th>Mail</th>
<th>Advanced</th>
<th>Space Admin</th>
</tr>
</thead>
</table>

You can move any page by dragging it to a new position in the tree.

- bookmarks
- Tree
- Navigation
- Home
- Sample Page
- Another Sample Page
- Yet Another Sample Page
- Something wicked this way comes
- Testing formats for Release Notes

If you change your mind, you can click the ‘Undo Sorting’ icon \(\text{B}\) to undo the alphabetical sort. This option is only available while you remain on the ‘Tree’ tab and provided that you have not performed any other action on the page family. Once you move away from this screen or do something else with the page family, such as moving children in or out of the family, the undo option is no longer available.

**What is a Page Family?**

In Confluence, you can organise pages into a hierarchy of parent and child pages. Pages in such a hierarchy are called a **page family**.

Page families are a simple but effective way of categorising content. Confluence makes navigation of your site easier by providing links forward and backwards through the page hierarchy.

A parent page is at the toplevel of that hierarchy. Subpages are called child pages or children.

For example, in your organisation, you may have a space for ‘Fun’. Under this space you could have the following pages:

Screenshot: Page Family
The 'Recreation' page in this hierarchy is the parent page and the 'Sports', 'Music' and 'Up Coming Trips' pages are its child pages. Together, they comprise a page family.

Confluence will only allow you to create page families that are a simple tree. This means that you can create any number of nested families but a child can have only one parent.

Working with Pages

Breadcrumbs
The breadcrumbs of a page display its location in the content hierarchy of Confluence. They trace the path from the current page back to the dashboard allowing easy navigation up and down the page hierarchy.

The breadcrumbs are displayed at the top of every page.

If you glance up at the breadcrumbs region of this page, above the title, you will see that it reads something like this:
Dashboard > Confluence > ... > Working with Page Families > Breadcrumbs

This means that this page is a child of 'Working with Page Families' which in turn is a part of the space 'Confluence'. The three dots '...' mean that there are other parent spaces between 'Confluence' and 'Working with Page Families'.

**Viewing Children of a Page**

Confluence displays the children of a page, if any exist, in one of two views configured globally by a site administrator:

**Show**: In this view, a list of the page's children is displayed as links at the bottom of the page. Clicking on a link will take you to the corresponding child page.

**Hide**: In this view, the list of the page's children is hidden when you view the page. A link at the bottom of the page tells you how many children the page has. Clicking on this link will display the list of its children.

**Screenshot : Show children**

**Viewing Hierarchy of Pages within a Space**

The 'Tree' view on the 'Browse Space' page displays the hierarchy of the pages within the space. It is a useful way of viewing all the parent-child relationships between pages in the space at a single glance.

**To see the tree view of pages within a space,**
1. Browse the space.

Go to the 'Browse Space' view. There are two ways to browse a space:

- Go to a page in the space and select the option you want from the 'Browse' menu. The corresponding tab of the 'Browse Space' view will open.
- Or click the icon next to the space name on the Dashboard. The 'Pages' tab of the 'Browse Space' view will open.

2. Go to the 'Pages' tab and open the 'Tree' view.
3. Click the '+' sign next to each page family to open the branches of the tree. This shows you the children of the page.

Changing Parent of a Page
In Confluence, you can organise pages into a hierarchy of parent and child pages. Pages in such a hierarchy are called a **page family**.

Page families are a simple but effective way of categorising content. Confluence makes navigation of your site easier by providing links forward and backwards through the page hierarchy.

A parent page is at the topmost level of that hierarchy. Subpages are called child pages or children.

To **change the parent of a page**, you can:

- Move the page to a new space, if that's what you want. You do this **while editing a page**.
- Move the page to a new position in the space's tree view. You do this **while editing a page or while viewing the space's Tree view**.

**RELATED TOPICS**

- Moving a Page
- Moving Pages within a Space
- Page Families
- Viewing a Page's Family
- Viewing a Page's Location within a Space
- Viewing Hierarchy of Pages within a Space
- Viewing Children of a Page
- Working with Pages

**Creating a Child Page**

To create a child page, you require 'Create Pages' permission which is assigned by a **space administrator** from the Space Administration screens. See **Space permissions** or contact a space administrator for more information.

Confluence allows you to create child pages in three different ways:

1. View an existing page. Go to the **Add** menu and select **Page**. By default, Confluence adds the new page as a child of the first.

2. Go to the **Add** menu and select **Page** from anywhere else in Confluence, then move the page to its required **Location** while still in edit mode — refer to the instructions on **moving a page**.

3. Click the **Add Child Page** link that is displayed when you choose to 'show' children of a page. This option is available only when the page already has children.

**RELATED TOPICS**

- Working with Page Families
- Viewing Children of a Page

**Viewing Page Information**

The **Information View** for a page shows you various bits of useful information about the page.

**To see the Information View for a page,**

1. View the page.
2. Go to the **Information** view for the page. To do this:
   - Go to a page in the space, open the **Tools** menu and select **Info**. The 'Information' view will open.

The 'Information View' displays the following information:

1. **Page Details**: Title, author, date of creation, date of last modification and the tiny link of the page.
2. **Page Hierarchy**: Parent-child relationships of the page.
3. **Page Permissions**: Displays page-level security restrictions that apply to the page (if present).
4. **Recent Changes**: Links to the five most recent versions of the page along with the name of the editor and the date of modification.
5. **View page history**: A link to the page history, which displays all the versions of the page in reverse chronological order and allows you to compare versions or to restore a previous version.
6. **Hot Referrers**: The external website pages which send the most viewers to the page.
Page History and Page Comparison Views

Confluence tracks histories of changes to pages by maintaining a version of the page each time it is modified. It is easy to view changes between different versions and to restore a previous version if required.

On this page:

- Accessing the Page History View
- Viewing Changes in a Page History
  - Viewing Recent Changes
  - Comparing Two Different Versions of a Page
- Page Comparison View
  - Key
  - Interactive views
- Other Page History View Features

Accessing the Page History View

To view the history of a page,

- Go to the page in the space, open the 'Tools' menu and select 'Page History'. The 'Page History' view will open. This will display a list of all versions of the page, ordered from newest at the top to oldest at the bottom of the list.
  - You can click a version number's link to view the contents of that page version. To get back to the page history view, click 'view page history'.

Screenshot: Page History View
If you are viewing a specific page version, the following functions are available:

- View the previous or next page versions by clicking ‘<< View previous version’ or ‘view next version >>’, respectively.
- Compare the differences between the version of the page you are viewing and the previous one by clicking ‘view differences’.

**Viewing Changes in a Page History**

The page history view and page information view allow you to view recent changes made to a page or to compare the differences between any two versions of a page.

**Viewing Recent Changes**

To view recent changes made to a page,

1. Click the ‘view change’ link at the top of the page below the page title. The page comparison view is displayed, showing text differences in wiki markup between the current and previous versions.
2. Go to the ‘Information’ view for the page. To do this:
   - Go to a page in the space, open the ‘Tools’ menu and select ‘Info’. The ‘Information’ view will open.
3. In the section titled ‘Recent Changes’ you will see the most recent versions of the page, along with the date of their modification and the name of the modifying author.
4. Click ‘view changes’ beside the desired version. The page comparison view is displayed, showing text differences in wiki markup between the selected and previous versions.

**Comparing Two Different Versions of a Page**

To compare two different versions of a page,

1. Access the page history view by:
   - Following the instructions at the top of this page.
   - Or
     a. Go to the ‘Information’ view for the page. To do this:
        - Go to a page in the space, open the ‘Tools’ menu and select ‘Info’. The ‘Information’ view will open.
        - Click the ‘View page history’ link in the ‘Recent Changes’ section. This will display a list of all previous versions of the page in reverse chronological order.
     b. Click the ‘view changes’ link in the ‘Recent Changes’ section. This will display a list of all previous versions of the page in reverse chronological order.
2. Select the versions you want to compare by selecting the check boxes beside them.
3. Click the ‘Compare selected versions’ button. The page comparison view is displayed, showing the text differences in Wiki markup between the selected versions.

**Page Comparison View**

The page comparison view shows the differences in wiki markup between selected page versions.

**Key**

On the page comparison view, the following key is used to depict wiki markup differences between the selected page versions:

- New lines or continuous sections of content are highlighted in green
- Removed lines or continuous sections of content are highlighted in red with a strike
- Whole lines containing only minor changes show the:
  - Additions highlighted in green
  - Deletions highlighted in red with a strike

**Screenshot: Comparing Changes**

```
This single line was removed.
This new line was added.
In this sentence, a single word was modified. changed.
```

**Interactive views**

When a page comparison view is first displayed, all large sections of unchanged text are hidden and reduced to an ellipsis ‘...’. Each one of these sections is ‘toggled’, such that:

- Clicking one of these ellipses reveals and expands the text it hides
Clicking an expanded section of text hides and contracts it back to an ellipsis.

You can also view page changes between versions which are adjacent to your current page comparison view. Click the link containing:

- '<<' to view the page comparison with the earlier adjacent version
- '>>' to view the page comparison with the more recent adjacent version.

For example, if your page comparison view is between v. 30 and v. 34 of a page, you can view changes between:

- v. 29 and v. 30 by clicking '<< Changes from 29 to 30'
- v. 34 and v. 35 by clicking 'Changes from 34 to 35 >>'

Screenshot: Interactive Page Comparison Views

**Other Page History View Features**

You can also use the page history view to:

- Restore an older version of a page
- View change comments

**RELATED TOPICS**

Tracking Updates

Take me back to the Confluence User Guide.

**Restoring an Older Version of a Page**

To restore an an older version of a page,
1. Go to the ‘Page History’ view. To do this:
   - Go to the page in the space, open the ‘Tools’ menu and select ‘Page History’. The ‘Page History’ view will open.
   - This will display a list of all versions of the page, ordered from newest at the top to oldest at the bottom of the list.
   - You can click a version number’s link to view the contents of that page version, or select the check boxes of two different versions and click ‘Compare selected versions’ to view the changes made between them. To get back to the page history view, click ‘View page history’.
2. Click ‘Restore this version’ beside the desired version.
3. Change the default comment if desired and click ‘OK’ to restore the desired version.

   If you are viewing a specific page version, you can restore that version of the page by clicking ‘restore this version’ on that page.

**Screenshot : Restoring an Older Version of a Page**

<table>
<thead>
<tr>
<th>Version</th>
<th>Date</th>
<th>Changed By</th>
<th>Operations</th>
</tr>
</thead>
<tbody>
<tr>
<td>CURRENT</td>
<td>Jul 07, 2009</td>
<td>Gilles Gaskell [Atlassian Technical Writer]</td>
<td></td>
</tr>
<tr>
<td>v. 41</td>
<td>Jun 18, 2007</td>
<td>Rosie Jameson [Atlassian Technical Writer]</td>
<td>Restore this version</td>
</tr>
<tr>
<td>v. 39</td>
<td>Jun 18, 2007</td>
<td>Rosie Jameson [Atlassian Technical Writer]</td>
<td>Restore this version</td>
</tr>
</tbody>
</table>

   All page history will be retained
   Restoring an older version creates a copy of that version. For example, in the above screenshot, if you selected v.39 and clicked ‘Restore this version’, a copy of v.39 would be created. This copy would be v.42 and would become the current version.

Moving a Page

This page tells you how to move a page which you are currently adding or editing. When you move a page, all attachments and comments on the page will be moved with the page. All child pages will move as well.
These instructions are for moving a single page

Using the method described below, you can only move the page which you are busy adding or editing. Alternatively, you can follow the instructions to move pages on the space’s Tree view.

Copying a page is different

If you want to copy rather than move a page, please refer to the instructions on copying a page.

To move a page, you need the following permissions:

- Edit permission on the page you are moving, and
- View permission on the page’s parent page. So if you are moving the page to a different parent, you need ‘View’ permission on the new parent.

On this page:

- Moving a Page
- About the Sequential Order of Pages
- Troubleshooting

Moving a Page

To move a page within the tree,

1. Make sure your page is in edit mode:
   - If you are creating a new page or copying a page, your page is already in edit mode.
   - If you want to move an existing page, view the page then click the ‘Edit’ button. Alternatively, you can go to the ‘Tools’ menu and select ‘Move’.
2. Click the ‘Edit’ button next to ‘Location’.
3. A tree view opens, highlighting the current page in its current position. See screenshot below. Holding down your left mouse button, click and drag the page up or down the tree.
4. Now you see one of the following:
   - A thin line between existing pages — This indicates the potential new position for the page. Release the mouse button when the page is where you want it.
   - A wide highlight over one or more existing pages — This indicates that you can drop the page into a page family. Release the mouse button to add the page to the family. The page will appear either in alphabetical sequence or as the last page in the family, depending on the family’s sequential order as described below.
5. Optional: Click the ‘Done’ button if you want to continue adding content to your page. This will close the tree view while leaving the page in edit mode.
6. Click the ‘Save’ button.
   - Note: The new position of the page is not saved until you click the ‘Save’ button.
   - To cancel the move while still holding down the mouse button, press the ‘Esc’ key on your keyboard.

To move a page to a different space,
1. Make sure your page is in edit mode:
   - If you are creating a new page, your page is already in edit mode.
   - If you want to move an existing page, view the page then click the ‘Edit’ button. Alternatively, you can go to the ‘Tools’ menu and select ‘Move’.
2. Click the ‘Edit’ button next to ‘Location’.
3. A tree view opens, with a ‘Space’ dropdown list. Select the space where you want to move the page.
4. The tree view is rebuilt, now showing the pages in the new space, and the current page is highlighted in its new position.
5. You can move the page to any position in the new space, as described above.
6. Optional: Click the ‘Done’ button if you want to continue adding content to your page. This will close the tree view while leaving the page in edit mode.
7. Click the ‘Save’ button.
   - Note: The new position of the page is not saved until you click the ‘Save’ button.
   - To cancel the move while still holding down the mouse button, press the ‘Esc’ key on your keyboard.
About the Sequential Order of Pages

Confluence allows you to present your pages in any order (sequence) you choose. The position of a page is reflected in the following places:

- The Tree tab on the space's 'Pages' view
- Space exports to PDF, HTML and XML
- The children of a page
- The pagetree macro
- The children macro

Alphabetical versus Manual Order

By default, Confluence will present your pages in alphabetical order. When you move a page to a different position, the order becomes manual for the affected page family.

When ordering pages alphabetically, Confluence actually applies a more sophisticated 'natural' order rather than a straight alphabetical order. The natural order handles numeric values correctly when doing string comparisons.

Now let's consider what happens when you add a page to a page family, by creating a new page or by moving or copying a page into the
Changing the Page Order

You can change the order of the pages by moving pages within the page family — simply move the page to its new position while editing the page (see Moving a Page) or while viewing pages in the space’s ‘Tree’ view (see Moving Pages within a Space).

You can also change the order of a page-family from manual to alphabetical (see the ‘Setting Page Order to Alphabetical’ section on Setting a Page Family to Alphabetical Order).

Troubleshooting

- Some people have experienced problems using the tree to move pages, after upgrading to Confluence 2.9. This is a known issue, that was fixed in Confluence 2.9.1. There is also a workaround for those who do not wish to upgrade to Confluence 2.9.1. Please see CONF-12911.

Moving Pages within a Space

Display an older version of a page

To point users to an outdated version of a page:

1. View the page and click the "view change" link displayed after the "last edited by" information.
2. In the box on the left-hand side of the "compared to", click on the "Version ## by Username" to show the full outdated version.
3. Click "<< View previous version" to scroll back through the outdated versions until you find the one you would like to link, and copy the URL from your address bar. This link is of the format http://confluence.atlassian.com/pages/viewpage.action?pageId=12345

These links inform the users that what they are viewing is out of date and provide a link to the current edition.

Linking pages

What would you like to do?

- Link to a page within a space
- Link to a page in another space
- Link to a webpage

RELATED TOPICS

Working with links
Working with pages

Recently Viewed Content

Confluence keeps track of pages you have recently visited throughout all your accessible spaces within a Confluence installation. This history is available from the Recently Viewed content view, which you can use to go back to Confluence pages you have recently visited.

To view the list of recently visited pages and go back to one of them,

1. Go to the ‘Recently Viewed’ content view. To do this:
   - Go to your name at the top of the page. (This is the ‘User’ menu. A dropdown list will appear when your cursor hovers over the ‘User’ menu.)
   - Select ‘Recently Viewed’ from the dropdown list. The ‘Recently Viewed’ content view will open.
2. Click the title of the page you wish to revisit.
Sequential Order of Pages

Confluence allows you to present your pages in any order (sequence) you choose. The position of a page is reflected in the following places:

- The Tree tab on the space's 'Pages' view
- Space exports to PDF, HTML and XML
- The children of a page
- The pagetree macro
- The children macro

Alphabetical versus Manual Order

By default, Confluence will present your pages in alphabetical order. When you move a page to a different position, the order becomes manual for the affected page family.

When ordering pages alphabetically, Confluence actually applies a more sophisticated 'natural' order rather than a straight alphabetical order. The natural order handles numeric values correctly when doing string comparisons.

Now let's consider what happens when you add a page to a page family, by creating a new page or by moving or copying a page into the family:

- If the page family's order is alphabetical, the new page will appear in alphabetical order too.
- If the page family's order is manual, the new page will appear at the bottom of the list of pages in the family.

Changing the Page Order

You can change the order of the pages by moving pages within the page family — simply move the page to its new position while editing the page (see Moving a Page) or while viewing pages in the space's 'Tree' view (see Moving Pages within a Space).

You can also change the order of a page-family from manual to alphabetical (see the 'Setting Page Order to Alphabetical' section on Setting a Page Family to Alphabetical Order).
Copying a Page

You can copy a page, to create a duplicate of the page content. You will need to rename the page, because a page name must be unique within a space.

You need ‘Create Pages’ permission, which is assigned by a space administrator from the Space Administration screens. See space permissions or contact a space administrator for more information.

To copy a page,

1. View the page you want to copy.
2. Go to the ‘Copy Page’ option. To do this:
   - Go to a page in the space, open the ‘Tools’ menu and select ‘Copy’.
     Confluence will open a copy of the page in edit mode. By default, Confluence will name the page ‘Copy of <<original page name>>’.
3. Rename the page and make any other changes required in the body of the page.
4. If you need to move the new page to a different space or a different parent, you can edit the ‘Location’. Refer to the instructions on moving a page.
5. Click ‘Save’.

More information about copying pages

- Copying a page will duplicate all of the original page’s attachments and labels, but will not copy comments from the original page.
- This method of copying a page does not copy the child pages. Please add your vote to issue CONF-2814 if you’d like to see this improvement.
- You can copy an entire space, including all pages in the space (parents and children) — refer to these instructions on copying a space.
- Consider using the WebDav plugin to move or copy a page hierarchy from one space to another, provided that none of the page names already exist in the target space.

Screenshot: Copying a page
Page Layout in Edit Mode (Rich Text)

Here's what the Confluence edit page looks like Rich Text mode:
Note

The options available to you in the ‘Edit’ mode of a page depend on the permissions granted to you by the space administrator.

**Commenting on a Page**

A comment is a remark, question, or any other additional information you wish to add to a page pertaining to the topic the page covers.

Comments are a means by which a community of users can interact with each other on the site.

You can leave a comment on any page or news item in Confluence.

What would you like to do?

- View Comments
- Add Comments
- Link to Comments
**Adding a Comment**

You can leave a comment on any page or news item in Confluence.

To add a comment, you require 'Create Comments' permission which is assigned by a space administrator from the Space Administration screens. See Space permissions or contact a space administrator for more information.

You can either add a new comment or respond to a previous comment (only available in 'threaded' view).

Use Confluence markup or the Rich Text editor to write the comment.

**Profile photo appears in comments**

Your profile picture will appear next to each comment you've added. (This is true if your space uses the Confluence Default theme.)

To add a new comment,

1. Click the 'Add Comment' link near the bottom of the page.
2. The comments box opens up. Type in your text.
3. Click the 'Preview' tab to see a preview of your comment.
4. You can tick the box next to 'Watch this page' to receive email alerts whenever the page is commented or edited.
5. Click the 'Post' button to save your comment and display it on the page.

You can also respond to a comment.

This option is only available when the comments are in 'threaded' view.

To respond to a comment,

1. Click the 'Reply' link located below the text of a comment.
2. This will open up a new comment box. Type in your text.
3. You can tick the box next to 'Watch this page' to receive email alerts whenever the page is commented or edited.
4. Click 'Post'.
Deleting Comments

To delete a comment from a page, you require 'Remove Comments' permission which is assigned by a space administrator from the Space Administration screens. See Space permissions or contact a space administrator for more information.

Currently, it is not possible to delete all comments for a page simultaneously.

To delete a comment,

1. Go to the page that contains the comment.
2. Click on the 'Remove' link located at the bottom of the comments box. This is only displayed if you have permission to remove comments for this page.

WARNING

Deleted comments cannot be restored.
1. Go to the comment and click the 'Edit' button. You can use Confluence markup or the Rich Text editor to edit a comment. You can click preview to see how it will appear.
2. You can tick the box next to 'Watch this page' to receive email alerts whenever the page is commented or edited.
3. When you're finished, click 'Save'.

**Screenshot 1: Editing a comment**

### Linking to Comments

⚠️ You need to edit in Wiki Markup mode to create a link to a comment.

To link to a comment from within Confluence,

1. Right-click on the 'Permalink' icon located at the lower right of the comments box. You will notice that the URL ends in a series of numbers.
2. Select the option to 'Copy the Link Location' the pop-up menu in your browser.
3. Paste the link into a temporary location and copy only the numerals at the very end of the link.
4. Click the 'Edit' tab of the page from which you want to link to the comment.
5. Paste the numerals between square brackets (as you would when you create any link in Confluence), and then include the dollar sign '$' in front of the numbers.

**Examples**

<table>
<thead>
<tr>
<th>Link to...</th>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>Comment in the same space</td>
<td>[$81167140]</td>
<td>Re: Linking to Comments (current space)</td>
</tr>
<tr>
<td>Comment in another space</td>
<td>[$81167141]</td>
<td>Re: Linking to Comments (CONF14 space)</td>
</tr>
</tbody>
</table>

Because you are linking to the actual database ID of the comment, you do not need to specify a space or a page id explicitly as that's calculated automatically from the database ID.
To link to a comment from outside Confluence,

1. Right-click on the 'Permalink' icon located at the lower right of the comments box.
2. Copy the link location of the comment. Alternately, click on 'Permalink' or the date and copy the URL displayed in the address bar of your browser.
3. Use this URL to link to the comment from your web page.

Take me back to Confluence User Guide

Sample Page

Start of sample page content

End of sample page content

child page

Viewing Comments

Comments on articles will appear by default in threaded form, below the page content. If the comment author is a Confluence user, a link appears to their profile page. The time of the comment’s last edit is also displayed – you can mouse-over the time to see the date and time it was posted.

Actions for Viewing Comments on a Page

Confluence allows you to 'collapse', 'expand', 'show' and 'hide' comments on a page.

- **Collapse All**
  - Comments are all shrunk to a single line, showing the first 60 characters. This allows easy browsing of many comments.
  - Clicking the top line of any comment will expand it, showing the links to 'Edit', 'Remove' or 'Reply'.

- **Expand All**
  - Comments are returned from the collapsed state to the usual threaded view, showing the full content of all comments inline.

- **Hide Comments**
  - The page’s comments will be hidden when you view the page. The 'Comments' line at the bottom of the page indicates...
whether the page currently has any comments.
- **Show Comments**
  - The page's comments will become visible below the page content.
  - Comment links at the bottom of each comment and the page allow you to post or manage comments.

### Setting the Appearance of Comments on Pages

Comments in Confluence are displayed in one of two views which is configured globally by a site administrator:

- **Threaded** - this view shows the comments in a hierarchy of responses. Each subsequent reply to a comment is indented to indicate the relationships between the comments.
- **Flat** - this view displays all the comments in one single list and does not indicate the relationships between comments.

⚠️ In Confluence 2.8.0, the collapsible comments are only available under the default Confluence theme.

**Screenshot: Threaded View**

Deleting a page

To delete a page, you require the 'Remove Pages' permission which is assigned by a space administrator from the Space Administration screens. See Space Permissions or contact a space administrator for more information.

To delete a page,

1. Go to the page.
2. Go to the 'Remove Page' option. To do this:
   - Go to a page in the space, open the 'Tools' menu and select 'Remove'. The 'Remove Page' screen opens. You will be prompted to confirm the action.
   - The 'Remove' menu option will only appear if you have permission to remove this page.

Handy Hint

- Deleted pages are stored in the trash and can be recovered by a space administrator.
- If the page you are deleting has any child pages they will be moved to the root of the space.

Purging Deleted Pages

When a user deletes a page from a Confluence space, the page is not permanently removed. Instead, Confluence places the deleted page into the 'Trash'. The page will remain in 'Trash' until a space administrator purges the page.

Purging deleted pages permanently clears them from 'Trash'.

You need to be a space administrator to purge deleted pages for a space.

To purge deleted pages,

1. Go to the 'Space Admin' tab of the Browse Space view. To do this:
   - Go to a page in the space, open the 'Browse' menu and select 'Space Admin'. The 'Space Administration' view will open.
   - 'Space Admin' is only displayed if you are a space administrator.
2. Click 'Trash' in the left-hand navigation panel. A list of deleted pages and news items for the space is displayed.
3. Click the 'Purge' link beside a page or else click 'Purge All' to permanently clear all deleted pages and news items.
Restoring a Deleted Page

When you restore a page, you are retrieving it from 'Trash' to the root of the space where it existed before it was deleted.

You need to be a space administrator to restore deleted pages.

To restore a deleted page,

1. Go to the 'Space Admin' tab of the Browse Space view. To do this:
   - Go to a page in the space, open the 'Browse' menu and select 'Space Admin'. The 'Space Administration' view will open.

   - 'Space Admin' is only displayed if you are a space administrator.

2. Click on 'Trash' from the left panel. A list of deleted pages and emails for the space is displayed.

3. Click on the 'Restore' link beside the page you want to restore.

   Handy Hint

   If a new page has already been created in that space with the same name as the deleted page, you will be given an option to rename the page before it is restored.

Deleting a page
Purging Deleted Pages

Writing Confluence pages

Confluence pages can be written in two ways:

- using a simple markup language called Wiki Markup

- or

- using the Rich Text editor: similar to editors available in standard text editing applications, the Rich Text editor allows you to enter content as you would in a Word document and apply formatting by clicking icons on a toolbar.

   NOTE

   While the Rich Text editor permits all formatting options possible with Wiki Markup, you will still need to use Wiki Markup for other more complex functions like macros.

   Help on the Wiki Markup language while you are writing a page

   A quick notation guide, Notation Help, appears beside the edit screen when you choose the Wiki Markup edit tab. You can then click the full notation guide link in the help window to view the full Notation Guide. This shows you the entire list of formatting and other complex operations that Confluence's notation permits, along with the markup detailing how to perform them.

Creating a New Page
Editing an Existing Page
The text in the image presents information on renaming and editing pages in Confluence. Below is the plain text representation of the document:

## Renaming a Page

To rename an existing page, you require 'Edit Pages' permission which is assigned by a space administrator from the Space Administration screens. See Space permissions or contact a space administrator for more information.

### Links and other references

- Confluence will automatically change all internal links to point to your new page title.
- Explicit references to your page title in macros will not be changed. You need to change these manually.
- Links from external sites will be broken, unless they use the page's permanent URL.

### To rename a page,

1. Go to the 'Edit Page' option. To do this:
   - Go to a page in the space, and select the 'Edit' button. The page will open for editing.
2. This will bring up the 'Edit' screen, as shown below. The page title is at the top of the edit panel (see screenshot below).
3. Change the page title as desired.
4. Click 'Save'.

### RELATED TOPICS

- Linking Pages
- Editing an Existing Page
- Working with Pages Overview

## Editing an Existing Page

To edit an existing page, you require 'Edit Pages' permission which is assigned by a space administrator from the Space Administration screen. See Space permissions or contact a space administrator for more information.

### To edit an existing page,

1. Go to the 'Edit Page' option. To do this:
   - Go to a page in the space, and select the 'Edit' button. The page will open for editing.
   
   This is only displayed if you have permission to edit the page. This will bring up the edit screen in either the Wiki Markup or the Rich Text mode, whichever is your current default.

2. Make changes to the content or add new content as you would when you create a new page. Click the tabs to switch between 'Rich Text' and 'Wiki Markup' edit modes. You can also use a combination of the two editors. Confluence retains changes made in one mode when you switch to the other.

3. Click 'Preview' to view your changes. Click 'Save'.
Pages with large amounts of text content

One user reported having problems saving a page that contained approximately 700 kilobytes (700,000 characters) or more of text content. Refer to CONF-16467 for more information. Some browsers appear to be more susceptible to this issue than others. While it is highly unlikely that your page content will ever reach this size, if you work with large pages, structuring your content into separate pages will help to avoid this issue.

Screenshots: Editing Modes in Confluence

Click thumbnail to see a Confluence page in Wiki Markup mode

Click thumbnail to see a Confluence page in Rich Text mode

More complex editing

- You can also rename a page while in edit mode.
- To view changes between different versions of the page, view the history of the page.
- While the Rich Text editor includes almost all formatting options possible with Wiki markup, you will still need to use wiki markup for more complex functions like Enabling and Configuring Macros.

Can Users Edit Individual Sections Within a Page?
Editing a Confluence Page in an Office Application

Take me back to Confluence User Guide

Concurrent Editing and Merging Changes

Sometimes, two or more people may edit a page at the same time. When this happens, Confluence will do its best to ensure that nobody’s changes are lost.

How will I know if someone else is editing the same page as I am?

If another user is editing the same page as you, Confluence will display a message above your edit screen letting you know who the other user is and when the last edit was made.

Screenshot: Notification of Simultaneous Page Editing

⚠️ This page is being edited by Vidya Nagabushni [last edit less than a minute ago]

What happens if two of us are editing the same page and the other user saves before I do?

If someone else has saved the page before you, when you click ‘Save’, Confluence will check if there are any conflicts between your changes and theirs. If there are no conflicting changes, Confluence will merge both the edits successfully. If there are any conflicts, Confluence will display them for you and give you the option to either ‘Overwrite’ the other user’s changes, ‘Merge changes’ manually, or ‘Discard’
Example Scenario

For example, Alice and Bob both edit the same page at the same time.

If Alice clicks save before Bob, Bob is now effectively editing an out-of-date version of the page. When Bob clicks save, Confluence will examine his changes to see if any overlap with Alice’s. If the changes do not overlap (i.e. Alice and Bob edited different parts of the page), Bob’s changes will be merged with Alice’s automatically.

If Bob’s changes overlap with Alice’s, Confluence will display an error message to Bob showing where Alice has changed the page, and giving Bob the options to overwrite Alice’s changes with his own, to re-edit the document to incorporate Alice’s work, or to cancel his own changes entirely.

Making Rich Text or Wiki Markup Editing Default

You can default to either ‘Rich Text’ or ‘Wiki Markup’ modes of editing depending on your preference.

To default to Rich Text or Wiki markup modes of editing,

1. Go to the ‘Edit Page’ option. To do this:
   * Go to a page in the space, and select the ‘Edit’ button. The page will open for editing.
   This will open up the page in your current default mode.

2. If the current edit mode is not your default, you can make it your default by clicking the ‘Make Default’ link beside the tabs.

The Wiki Markup button cannot be hidden in the editor window.

Recording Change Comments

A change comment is a short description that details the changes made to a page during an edit. Change comments are a useful way of keeping track of the history of a page.

A ‘change comment’ is not the same as a comment added to a page. Refer to Commenting on a Page for information about that type of comment.

Cannot update or remove a change comment

Once a change comment has been added and the page has been saved, it is not possible to update or remove the change comment.

Entering a Change Comment
You can enter change comments in the field located below the edit screen:

**Screenshot: Entering change comments**

<table>
<thead>
<tr>
<th>Comment:</th>
<th>Added the cheese macro</th>
</tr>
</thead>
</table>

**Viewing a Change Comment**

Once a comment has been added, it becomes visible in the view mode of the page, so that users are aware of the most recent changes made to a page. If a comment has been recorded, you will see a 'show comment' link below the page title. Click the link to view the comment.

**Screenshot: The 'show comment' link**

Take me back to Confluence User Guide
Creating a New Page

To create a page, you need the 'Create Pages' permission which is assigned by a space administrator from the Space Administration screens. See space permissions or contact a space administrator for more information.

You can also read more about writing pages.

There are few ways to add a new page, described in more detail below:

- Using the Add Page Option
- Using an Undefined Link to Create a Page
- Importing an Office Document into One or More Confluence Pages

Using the Add Page Option

To add a page,

1. Go to the 'Add Page' option. To do this:
   - Go to a page in the space, open the 'Add' menu and select 'Page'. The 'Add Page' screen opens.
   - Alternatively, you can go to the Dashboard and click the 'Add Page' link located beside each space. In this case, Confluence will add the page at the root of the space.
   - The 'Add Page' links are only displayed if you have permission to create pages for the space.
2. Enter a name (title) for your page.
3. By default, Confluence will add the page as a child of the page you are viewing. If you need to move the new page to a different space or a different parent, you can edit the 'Location'. Refer to the instructions on moving a page.
4. Enter content for your page using Wiki Markup or the Rich Text editor. See Writing Confluence pages.
5. Click 'Preview' if you want to see a preview of what the page will look like before saving it.
6. Click 'Save'.

Pages with large amounts of text content

One user reported having problems saving a page that contained approximately 700 kilobytes (700,000 characters) or more of text content. Refer to CONF-16467 for more information. Some browsers appear to be more susceptible to this issue than others. While it is highly unlikely that your page content will ever reach this size, if you work with large pages, structuring your content into separate pages will help to avoid this issue.

Using an Undefined Link to Create a Page

In Confluence, you can add a link which points to a page that you intend to create later. You might also use such a link to prompt other Confluence users to create pages. This type of link is called an undefined link.

To add an undefined link for later creation of a page,

1. Add a link, by typing a page name between angle brackets `[]` into your page body, specifying the name of a page which does not exist. See example below.
2. Save the page which contains the undefined link. Confluence indicates undefined links by colouring them red.
3. When you (or another user) click on the link, the 'Add Page' screen appears.
4. You can then follow the steps outlined above to enter the page name, add content and save the page.

Here is an example of an undefined link:

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>[Link to new page]</td>
<td>[Link to new page]</td>
</tr>
</tbody>
</table>

Screenshot: Adding a page
Page names

- Confluence does not accept the following characters in the title of a page:

  :,:/@,"\|^#;[\]{},<>

- A page must not start with the following characters:

  $,,~

- Page names must be unique within a space. We are aware that this is a limitation, and there's a feature request at CONF-5926. If you like, you can vote for this feature and add yourself as a watcher for future updates. You can also vote for the improvement request CONF-9458 to remove the restrictions on characters.

Importing an Office Document into One or More Confluence Pages

The Office Connector allows you to import a Word document into Confluence, optionally creating one or more new pages. See Importing an Office Document into Confluence.

Confluence Notation Guide Overview
Editing an Existing Page
Working with Page Families
Working with Drafts Overview

A draft is a snapshot version of a page which Confluence saves automatically at regular intervals while you are editing the page. Confluence saves these interim versions even if you do not save the page yourself. This is useful to prevent you losing work if your Confluence site experiences a problem.

At regular intervals, Confluence will automatically save the page you are editing and maintain a copy of it as a draft. If some system failure or error prevents you from saving your changes, you can retrieve the draft and continue working on it.

- Drafts are created while you are adding and editing a page or news item.
  
  Each time Confluence saves a draft of your page, it displays a message and the time of the last save. The message appears near the 'Save' button on the edit screen.

  *Screenshot: Message displaying the time when the draft was last saved*

  Draft saved at 11:37 AM  
  Save  
  Cancel

Whenever you edit a page and click one of the other page tabs, Confluence will automatically save a draft. When you click on the 'Edit' tab again, Confluence will let you know that a version of the page you are editing was not saved and will give you the option to resume editing.

- By default, Confluence saves a draft of your page once every thirty seconds. However, a Confluence administrator can configure how often drafts are saved.

- A draft is only available to you if you have been working on a page and have not yet saved your changes.

- You cannot create a draft explicitly.

- Drafts are listed in the 'Drafts' tab of your profile. Only you can view and edit your drafts.

- Once you have resumed editing a draft, or chosen to discard it, it is removed from this view.

Concurrent Editing and Merging Changes

Resuming the Editing of a Draft

Confluence will save a draft of the page even if you haven't successfully added the page yet.

There are two ways to resume editing the page:

1. To see your drafts, go to your name at the top of the Confluence screen. Select 'Drafts' from the dropdown menu as shown here. A draft of the page will be listed with an option to 'Resume Editing'.

   RELATED TOPICS

   Working with Drafts Overview  
   Viewing Drafts

Confluence 3.0 Documentation
1. If you had not yet entered a page title, the draft will be listed without a title.

<table>
<thead>
<tr>
<th>Title</th>
<th>Last Saved Date</th>
<th>Operations</th>
</tr>
</thead>
</table>

2. If you do not resume editing the page as described above: When you next click 'Add Page' in that space, Confluence will ask you if you want to resume editing the page that wasn't saved. You can choose to resume editing. This will restore the page.

What happens if I am editing the draft of a page that has since been updated?

When this happens, Confluence will display a message informing you that you are editing an outdated page. If there are no conflicts between the two versions, Confluence will give you the option to 'Merge and Resume editing'.

If there are any conflicts, Confluence will give you the option to 'View the Conflict' or to 'Discard' your changes.

Viewing Drafts

To see your drafts, go to your name at the top of the Confluence screen. Select 'Drafts' from the dropdown menu.

Your drafts will appear, listed on the 'Drafts' tab in your user profile.
Introduction to Confluence's WebDAV Client Integration

WebDAV allows users to access Confluence content via a WebDAV client, such as 'My Network Places' in Microsoft Windows. Provided that the user has permission, they will be able to read and write to spaces, pages and attachments in Confluence. Users will be asked to log in and the standard Confluence content access permissions will apply to the equivalent content available through the WebDAV client.

By default, all WebDAV clients have permission to write to Confluence. Write permissions include the ability for a WebDAV client to create, edit, move or delete content associated with spaces, pages and attachments in a Confluence installation.

This page provides instructions on how you can set up a WebDAV client natively for a range of different operating systems. WebDAV clients typically appear as drives in your operating system's file browser application, such as 'Windows Explorer' in Microsoft Windows, 'Finder' in Mac OS or 'Konqueror' in Linux.

Setting Up a WebDAV Client in Microsoft Windows

This section covers the two methods for configuring a WebDAV client natively in Microsoft Windows:

- As a network drive
- As a web folder

If possible, use the network drive method as this will enable more comprehensive WebDAV client interaction with Confluence than that provided by a web folder. However, your Confluence instance must meet several environmental constraints if you use this method. If you cannot configure your instance to meet these requirements, then use the web folder method or third-party WebDAV client software.

Windows Network Drive

To map a Confluence WebDAV client network drive, your Confluence instance must be configured so that all of the following criteria is met:

- Uses HTTP (not HTTPS)
- Listens on port 80 (not 8080, which is the default port value used by the popular application server Apache Tomcat that runs many Confluence installations and Confluence Standalone distributions)
- Has no context root

The reason for these restrictions results from limitations in Microsoft's Mini-Redirector component. For more information, please refer to Microsoft's server discovery issue.
To map a Confluence WebDAV client network drive in Microsoft Windows,

1. In Windows XP, go to My Computer -> Tools menu -> Map Network Drive. In Windows Vista, go to Computer -> Map Network Drive. The 'Map Network Drive' dialog box opens.
2. Specify the following input to map the WebDAV client as a network drive:
   - Drive: <Any drive letter> (for example, Z:)
   - Folder: \\<hostname>\webdav (for example, \\localhost\webdav)
3. Click 'Finish'.

When prompted for login credentials, specify your Confluence username and password.

Screenshot: A Confluence WebDAV Client Network Drive in Windows XP

Windows Web Folder

To map a Confluence WebDAV client web folder in Windows XP,

1. Go to My Network Places and choose 'Add a network place'. The 'Add Network Place Wizard' opens.
2. Click 'Next', ensure that 'Choose another network location' is selected and then click 'Next' again.
3. In the 'Internet or network address' field, enter the URL for the Confluence WebDAV location (for example, http://<confluence server url>/confluence/plugins/servlet/confluence/default or http://<confluence server url>/plugins/servlet/confluence/default) and then click 'Next'.

When prompted for login credentials, specify your Confluence username and password.
4. Provide a meaningful name for your web folder and proceed with the remainder of the wizard.
5. Click 'Finish'.

Screenshot: A Confluence WebDAV Client Web Folder in Windows XP
To map a Confluence WebDAV client web folder in Windows Vista,

This procedure is very similar to the one for Windows XP. However, the following procedure includes the slight interface differences that are specific to Windows Vista.

1. Open the 'Map Network Drive' dialog box (refer to first step of the procedure above for mapping a network drive) and choose 'Connect to a Web site that you can use to store your documents and pictures'. The 'Add Network Location' wizard opens.
2. Click 'Next', ensure that 'Choose a custom network location' is selected and then click 'Next' again.
3. In the 'Internet or network address' field, enter the URL for the Confluence WebDAV location (for example, http://<confluence server url>/confluence/plugins/servlet/confluence/default) and then click 'Next'.
4. When prompted for login credentials, specify your Confluence username and password.
5. Provide a meaningful name for your network location/web folder and proceed with the remainder of the wizard.
6. Click 'Finish'.

Setting up a WebDAV client in Mac OS

To set up a Confluence WebDAV client in Mac OS,

1. Open the Finder.
2. From Go on the Finder Menu, select Connect to Server or press Command+K, which will also bring up this dialog box.
3. In the 'Server Address' field, enter the URL for the Confluence WebDAV location (for example, http://<confluence server url>/confluence/plugins/servlet/confluence/default or http://<confluence server url>/plugins/servlet/confluence/default) and click 'Connect'.
4. When prompted for login credentials, specify your Confluence username and password.

Screenshot: Setting Up a WebDAV Client in Mac OS
Setting up a WebDAV client in Linux or Unix

There are many tools and mechanisms available for configuring WebDAV clients in these operating systems. Therefore, we have chosen to demonstrate this using the file manager Konqueror, which is part of the Linux K Desktop Environment.

To set up a Confluence WebDAV client in Konqueror,

1. Open Konqueror.
2. In the 'Location' field, enter the URL for the Confluence WebDAV location using the 'protocol' webdavs (for example, webdavs://<confluence server url>/confluence/plugins/servlet/confluence/default or webdavs://<confluence server url>/plugins/servlet/confluence/default) and press Enter.

   If prompted for login credentials, specify your Confluence username and password. You should be able to click to load many, but not all files. In practice, you would normally save a modified file locally, then drag it to the Konqueror window to upload it to Confluence.

Dashboard

The Dashboard is the front page of a Confluence site. It provides an overview of the site, access to all spaces to which you have 'view' permission, and displays a list of the most recently updated content within them.

You can go to the Dashboard from any page on your site by clicking on the logo beside the page title or via the Breadcrumbs (the "You are here" path) located at the top of every page.

The dashboard is divided into five sections:

1. The Welcome Message for the site, which is configured from the Administration Console.
2. A list of the spaces within the site to which you have access, presented via convenient tabs: 'My', 'Team', 'New' or 'All' spaces. See Customising the Dashboard.
3. A list of the most Recently Updated documents on the site from the spaces listed. For example, if you click on the tab 'Team', the recently updated content from your team spaces will be listed here.
4. A list of your Favourite Pages. See Working with Favourites.
5. Useful links:

   a. Create a space — see Setting up a New Global Space
   b. — see Using the RSS Feed Builder
   c. — see Searching the People Directory

The Dashboard is the only place in Confluence from where you can:

- access all existing spaces on the site.
- add a new space to the site.

By default, the Dashboard is also the site homepage. However, you can set any other page in Confluence as the homepage via the Space Admin tab or your User Profile settings.
Customising the Dashboard

You can customise the Dashboard to provide access to the content on the site that is most relevant to you.

1. If you are using Confluence Hosted for Small Business, please note that some Confluence features are excluded from the Confluence Hosted for Small Business edition. See the feature comparisons on our website and in our documentation.

On this page:
- Displaying your Favourite Spaces
- Displaying your Team's Spaces
- Displaying your Favourite Pages
- Global Modifications

Displaying your Favourite Spaces

Mark some spaces as favourite. See Adding Favourites. Once you have marked your favourite spaces, you can click on the 'My' tab in the spaces section of the Dashboard to view a list of only your favourite spaces. The 'Recently updated' section in this view will also display content only from these spaces.

Displaying your Team's Spaces
Add a team label to the spaces important to your team. See **Adding a Team Label**. Team labels are used to group together related spaces. For example, you may want to group together all spaces relating to a project team.

Once you have added team labels, you can click on the 'Team' tab in the spaces section, select a team from the drop down menu, and have only the list of spaces pertaining to that team displayed. The 'Recently updated' section in this view will also display content only from these spaces.

The Dashboard remembers which one of the views, 'My', 'Team', 'All' or 'New' you were most recently viewing. So if you clicked the 'My' tab on this visit, next time around, as soon as you log in to Confluence, only the list of your favourite spaces and the recently modified content within them will be displayed to you.

**Displaying your Favourite Pages**

Mark your favourite pages. See **Adding Favourites**. Whichever view you are in, the Dashboard will display a list of your five most recently added favourite pages, so you can access those pages easily.

**Global Modifications**

If you are a Confluence Administrator, you can modify files to add content to the global dashboard. See **Customising the dashboard for Administrators**.

<tr>
<td><img src="image" alt="News icon" /></td>
<td>View a piece of news.</td>
</tr>
</tbody>
</table>
Working with Spaces Overview

In Confluence, content is organised into spaces. There are two types of spaces:

- **Global** spaces are areas on your site into which you can group content items (pages, attachments, news, etc) based on any theme or topic of your choice. For example, you may want separate areas on your site for each team or project within your organisation. In Confluence, you can set up a different space for each team or project. You can build content for each of these spaces individually, decide who its users are, and even archive mail separately within each. There is no limit to the number of global spaces you can create within Confluence!
Personal spaces belong to particular users, and rather than being listed on the Dashboard (see below), are available from the People Directory. They can contain pages and news items, be searched and browsed. They can be kept private, or opened up so the whole world can view and edit them, just like global spaces.

Confluence treats each space as an independently managed wiki. This means that each space functions autonomously within your site.

Each space:

- Has its own pages, news items, comments, bookmarks (if the Bookmarks Plugin is enabled), RSS feeds and mail (mail applies to global spaces only).
- Has its own access control settings, so you can set different levels of access to different spaces.
- Can be separately exported to PDF, HTML or XML.

You can view all the global spaces within a site via the Dashboard. You also group global spaces together into 'Team Spaces' or 'My Spaces' to enable easy access to the content that is most relevant to you. See Customising the Dashboard.

Here is an example of how you could categorise information using spaces:

<table>
<thead>
<tr>
<th>Spaces:</th>
<th>My</th>
<th>Team</th>
<th>New (1)</th>
<th>All</th>
</tr>
</thead>
<tbody>
<tr>
<td>Confluence (DOC)</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Confluence 1.4 User Guide (CONF14)</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Confluence 2.0 User Guide (CONF20)</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Documentation Staging (DOCPRIV)</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Documentation Staging 2 (DOCPRIV2)</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

'My' spaces are spaces that you have nominated as your favourites.

Administering Spaces

To view the space administration menu,

Go to the ‘Space Admin’ tab of the Browse Space view. To do this:

- Go to a page in the space, open the ‘Browse’ menu and select ‘Space Admin’. The ‘Space Administration’ view will open.

‘Space Admin’ is only displayed if you are a space administrator.

All the options pertaining to the management of a space are listed in the left panel. Click on a link to take you to the corresponding screen.

To administer a personal space,

For personal spaces, the options available are divided into three categories under these headings:

1. Space Operations
   - Edit a space’s details
   - Edit space labels and team labels
To administer a global space,

Note that you need to be a space administrator to perform administrative functions relating to a global space.

For global spaces, the options available are divided into five categories under these headings:

1. **Space Operations**
   - Edit a space's details
   - Edit space labels and team labels
   - Remove a space
   - Purge or restore content from trash

2. **Security**
   - View or set space permissions
   - View restricted pages

3. **Mail**
   - Manage mail accounts
   - Import mail

4. **Look and Feel**
   - Apply a theme
   - Change the colour scheme
   - Edit the space's layouts
   - Change the space's logo

5. **Import**
   - Importing Pages from Disk

*Screenshot: Space Administration menu for a global space*
Browsing a space

The 'Browse Space' view gives you access to:

- Space-wide views of the content of the space — pages, news, labels, attachments, bookmarks and mail.
- Summary information about the space.
- Advanced space management tools.
- Tools to administer the space (for space administrators only).

The components of the Browse Space view are organised into a number of blue tabs.

Go to the 'Browse Space' view. There are two ways to browse a space:

- Go to a page in the space and select the option you want from the 'Browse' menu. The corresponding tab of the 'Browse Space' view will open.
- Or click the icon next to the space name on the Dashboard. The 'Pages' tab of the 'Browse Space' view will open.

Screenshot: Browsing a space — 'Advanced' tab
The tabs that are displayed will depend on your Confluence site configuration, the type of space you are viewing and the space permissions granted to you for the space.

### Editing Space Details

You need to be a space administrator to edit the details of a space.

To edit the details of a space,
1. Click the 'Browse Space' link for the space. This is located at the top of every page and beside the space link on the Dashboard.
2. Go to the 'Space Admin' tab and click 'Edit Space Details' in the left-hand panel. This brings up a new screen where you can:
   - Enter a different name for the space.
   - Enter or modify the space description.
   - Select a new home page for the space from the drop-down menu. This is the default page to which users are directed when they click the link to the space from the Dashboard.
   - If you set this field to blank (no selection) then the default home page will be the 'Pages' tab of the 'Browse Space' page.
3. Click 'Save'.

**Note**

You cannot edit the key or the creator's name.

**RELATED TOPICS**

Viewing Space Details

**Managing Orphaned Pages**

An orphaned page is a page without any incoming links. What this means is that unless you know that this page exists, you are not likely to come across it in the space during the natural course of navigation.

When you are working in a large space with a number of pages, it is difficult to keep track of all of them. An orphaned page may be redundant or need to be referred to from another page. Confluence allows you to view all the orphaned pages in a space so you can "tidy up" the space by either deleting pages or by reorganising them.

To view the orphaned pages in a space,

1. Click on the 'Browse Space' link for the space. This is located at the top of every page and beside the space link on the dashboard.
2. Go to the 'Advanced' tab and click on 'Orphaned Pages' from the left panel.

You can:

- delete an orphaned page by clicking on the 'trash' icon beside it.
- give an orphaned page a parent — see Changing Parent of a Page.

**Screenshot : Managing Orphaned Pages**

**RELATED TOPICS**

Managing Undefined Pages
Browsing a space
Managing Undefined Pages

In Confluence, you can create links to pages that you intend to create later. This is a useful facility as it allows you to create links first and enter content for those pages later. These are 'undefined links' and are indicated with this sign to remind you that those pages need to be created.

For example, [Link to new page]

Because you may be working with a large number of pages each with a number of links, this view gives a consolidated report of all the undefined pages so you can manage your space better.

To view the undefined links in a space,

1. Click on the 'Browse Space' link for the space.
2. Go to the 'Advanced' tab and click on 'Undefined Links' from the left panel. This will display a list of all the undefined pages in the space.
   
   Click on the 'Add Page' icon beside a page to add content.

Viewing Space Details

To view a space's details,

1. Click the 'Browse Space' link for the space. This is located at the top of every page and beside the space link on the dashboard.
2. Go to the 'Advanced' tab and click 'Space details' in the left-hand panel.

The following details are displayed:

- The Name of the space.
- The Key used to refer to the space. This key is a shorthand name for the space that is used for web urls, reports, and when linking content between spaces. Note that personal space keys always contain a '~', whereas global space keys never do.
- Any Labels defined for this space. Optional.
- The Homepage of the space. Optional. This is the default page to which users are directed when they click on the link to the space from the dashboard. If this field is empty (not displayed) then the default home page is the 'Pages' tab of the 'Browse Space' page.
- The Creator of the space.
- The Space Description: Optional. This is a short description of the space used to provide users with an idea of the space's contents.

Here is an example:

Screenshot : Space Details
Converting a Global Space to a Personal Space

Generally, the easiest way to create your personal space is to follow the instructions described in Setting up your Personal Space. However, sometimes you may need to convert an existing global space into a personal space, particularly if you used Confluence before the introduction of personal spaces in version 2.2.

To convert a global space to a personal space, you require the following permissions:

- ‘Personal Space’ permission, which is assigned by a Confluence administrator from the Administration Console. See Security or contact a Confluence administrator for more information.
- ‘Space Admin’ permission, which is assigned by a space administrator.

To convert a global space to a personal space,

1. Go to the global space.
2. Go to the ‘Space Admin’ tab of the Browse Space view. To do this:
   - Go to a page in the space, open the ‘Browse’ menu and select ‘Space Admin’. The ‘Space Administration’ view will open.
   - ‘Space Admin’ is only displayed if you are a space administrator.
3. Click the ‘Edit Space Details’ link in the left panel.
4. In the ‘Convert to Personal Space’ section, in the lower half of the screen:
   - Choose whether to Update Links to pages in this space (recommended).
   - Choose the User whose personal space this global space will become.
   - Click the ‘Convert Space’ button.

Screenshot: Converting a Global Space to a Personal Space

Convert to Personal Space

Convert this space into a Personal Space for yourself or another user. Note that every user can only have one personal space. If you select a user, this space will be converted into your own Personal Space.

You can choose to update all existing links to pages in this space. This operation might take a few minutes to complete.

Update Links:  
Choose Owner:  
Add
Convert Space
Note that the ability to archive mail and import pages from disk applies only to global spaces, so the 'Mail' and 'Import' sections in the above screenshot do not appear in the 'Space Admin' tab for personal spaces. Please see Working with Spaces Overview for information about the differences between global spaces and personal spaces.

### Deleting a Space

Deleting a space permanently removes the space and all of its contents.

⚠️ **Warning**

Use caution while deleting a space, and always create an XML Space Backup before proceeding. Once deleted, there is no way to restore a space unless you have made an XML Space Backup.

You need to be a space administrator to delete a space.

**To delete a space,**

1. Go to the 'Space Admin' tab of the Browse Space view. To do this:
   - Go to a page in the space, open the 'Browse' menu and select 'Space Admin'. The 'Space Administration' view will open.
   - 'Space Admin' is only displayed if you are a space administrator.
2. Click on the 'Remove Space' link in the left panel under the heading 'Space Operations'.
3. Click 'OK' when the confirmation screen is brought up.

### Guidelines For Partitioning Content Into Spaces & Pages

Brief guidelines for grouping content into the Confluence space and page format used by Confluence.

**Partitioning Guidelines**

To ensure maintainable and logical spaces, content should be broken into spaces by:

1. Evaluating permissions across the wiki content. If members require conflicting access, for example user 1 must access content on topics A and B, while user 2 must access content for topics B and C, then the topics must be separated into three spaces.
2. Grouping content by topic, project or team.

For semi-static content, a space for each topic is fine. If there is a substantial project-related content that must be exclusive to different groups, you should use separate spaces.

**Spaces & Pages Information**
Useful notes about spaces and pages:

1. Spaces cannot be nested
2. Page permissions can prevent users who can access the space from accessing that page
3. Page permissions alone cannot keep the existence of a page secret. The page should be in a restricted space instead
4. Pages can be easily moved between spaces

Moving Content from one Space to Another

While each space in Confluence functions independently, Confluence is flexible enough to let you move content easily between spaces.

What would you like to do?

Move a Page from one Space to Another
Move a Family of Pages from one Space to Another
Move an Attachment

Browsing a space

Take me back to Confluence User Guide

Moving a family of pages from one space to another

To move page families, you require 'Create Pages' permission for each page in that family. Space Permissions are assigned by a space administrator from the Space Administration screens.

Confluence allows you to move pages around by dragging and dropping them on a tree view. When you move a parent page, all its children are automatically moved too.

To move an entire family of pages, you can:

- Move the page family to a new space, if that's what you want. You do this while editing a page.
- Move the page family to a new position in the space's tree view. You do this while editing a page or while viewing the space's Tree view.

Moving a Page from one Space to Another

You can easily move pages from one space to another within Confluence.

To move a page, you require 'Create Pages' permission which is assigned by a space administrator from the Space Administration screens. See Space permissions or contact a space administrator for more information.

To move a page to a new space, you need to edit the page's location — refer to the instructions on moving a page.

Handy Hint

Any links to the page from the current space will automatically be renamed to point to the page in the new space.

Moving Pages within a Space

This page tells you how to move a page using a space's 'Tree' view. This method allows you to move a page, or a family of pages, within a space. Alternatively, you can move a page to a new position or to a new space while in edit mode — see Moving a Page.
To move a page, you need the following permissions:

- Edit permission on the page you are moving, and
- View permission on the page's parent page. So if you are moving the page to a different parent, you need 'View' permission on the new parent.

When you move a page, its children will move as well.

### On this page:

- About the Sequential Order of Pages
- Moving a Page
- Setting Page Order to Alphabetical
- Troubleshooting

### About the Sequential Order of Pages

Confluence allows you to present your pages in any order (sequence) you choose. The position of a page is reflected in the following places:

- The Tree tab on the space's 'Pages' view
- Space exports to PDF, HTML and XML
- The children of a page
- The pagetree macro
- The children macro

### Alphabetical versus Manual Order

By default, Confluence will present your pages in alphabetical order. When you move a page to a different position, the order becomes manual for the affected page family.

When ordering pages alphabetically, Confluence actually applies a more sophisticated 'natural' order rather than a straight alphabetical order. The natural order handles numeric values correctly when doing string comparisons.

Now let's consider what happens when you add a page to a page family, by creating a new page or by moving or copying a page into the family:

- If the page family's order is alphabetical, the new page will appear in alphabetical order too.
- If the page family's order is manual, the new page will appear at the bottom of the list of pages in the family.

### Changing the Page Order

You can change the order of the pages by moving pages within the page family — simply move the page to its new position while editing the page (see Moving a Page) or while viewing pages in the space's 'Tree' view (see Moving Pages within a Space).

You can also change the order of a page-family from manual to alphabetical (see the 'Setting Page Order to Alphabetical' section on Setting a Page Family to Alphabetical Order).

### Moving a Page

To move a page within the space's 'Tree' view,

1. Go to the 'Space Pages' view for the current space. To do this:
   - Go to a page in the space, open the 'Browse' menu and select 'Pages'. The 'Space Pages' view will open.
2. Go to the 'Tree' tab.
3. A tree view opens. Find the page you want to move.
   - Hint: Click the '+' sign next to each page family to open the branches of the tree.
4. Holding down your left mouse button, click and drag the page up or down the tree. See screenshot below.
5. While dragging the page, you see one of the following:
   - A thin line between existing pages — This indicates the potential new position for the page. Release the mouse button when the page is where you want it.
   - A wide highlight over one or more existing pages — This indicates that you can drop the page into a page family. Release the mouse button to add the page to the family. The page will appear either in alphabetical sequence or as the last page in the family, depending on the family's sequential order as described below.
   - Note: The new position of the page is saved as soon as you release the mouse button.
   - To cancel the move while still holding down the mouse button, press the 'Esc' key on your keyboard.
Setting Page Order to Alphabetical

If the pages in a page family have been ordered manually, you can reset the page order to alphabetical as described below.

A page family is a set of pages under a single parent page. In this section, when we say 'page family' we mean the immediate children of the parent page, not including the grand-children.

The screenshot below shows a family of pages in non-alphabetical order under the parent 'Sample Page'. Notice the icon next to the parent 'Sample Page', giving you the option to order the pages alphabetically.

To set a page family to alphabetical order,
1. Go to the 'Space Pages' view for the current space. To do this:
   - Go to a page in the space, open the 'Browse' menu and select 'Pages'. The 'Space Pages' view will open.
2. Go to the 'Tree' tab. The tree view will open, as shown in the screenshot above.
3. Expand the branches of the tree to find the page family you want.
4. If the page family is in non-alphabetical (manual) order, the 'Sort Alphabetically' icon  will appear next to the parent page as shown in the screenshot above. Click the icon.
5. The child pages will shuffle into alphabetical order and the icon will change to the 'Undo Sorting' icon  as shown in the screenshot below. Only the immediate children of the parent page will be affected. The grand-children will not be re-ordered. (If you want to re-order the grand-children, you need to click the 'Sort Alphabetically' icon next to the parent of those pages i.e. re-ordering happens for one node at a time.)

If you change your mind, you can click the 'Undo Sorting' icon  to undo the alphabetical sort. This option is only available while you remain on the 'Tree' tab and provided that you have not performed any other action on the page family. Once you move away from this screen or do something else with the page family, such as moving children in or out of the family, the undo option is no longer available.

**Troubleshooting**

- Some people have experienced problems using the tree to move pages, after upgrading to Confluence 2.9. This is a known issue, that was fixed in Confluence 2.9.1. There is also a workaround for those who do not wish to upgrade to Confluence 2.9.1. Please see CONF-12911.

**Setting up a New Global Space**

To set up a new global space, you require 'Create Space' permission which is assigned by a Confluence administrator from the Administration Console. See Security or contact a Confluence administrator for more information.

To create a new global space,
1. Click the link ‘Create a Space’ located below the list of spaces on the Dashboard.
2. The ‘Create Space’ screen appears, as shown below. Enter the following information about your new space:
   - **Space Name**: Type a name for the space. Note that space names do not have to be unique.
   - **Space Key**: Type a simple key to identify your space (A-Z, a-z, 0-9). This key is a shorthand name for the space, used when linking content between spaces, for web URLs and for reports. The space key must be unique within the entire Confluence site.
   - **Permissions**: Leave the default settings or choose to allow only yourself to view or contribute content to this space. A space administrator can change the permissions at any time after creating the space.
   - **Theme**: Select a theme for your space. A space administrator can change the theme later too.
3. Click the ‘OK’ button. (It's at the bottom of the screen, not shown on the screenshot below.)
4. The ‘Home’ page for your new space is displayed.
   - **Note**: Your home page will automatically contain any default space content as defined by your Confluence administrator.
5. Click ‘OK’.

Next, you can start adding pages to your space.

**Screenshot: Creating a space**

- **Enter a space name**
- **Enter a space key**
- **Who can use this space?**
  - Choose who can view and comment on content:
    - Me
    - Registered users - anyone logged into Confluence
  - Choose who can contribute (create and edit) content:
    - Me
    - Registered users - anyone logged into Confluence

**Choose Theme**

To change the theme of this space, select one below:

- **Default Theme**
  - Use the globally configured look and feel. You can customise colour schemes and layouts manually.
- **Confluence Classic Theme**
  - Confluence Classic Theme (with old typography)

**RELATED TOPICS**
Setting up your Personal Space

Your personal space is a place where you can publish your own pages and news items. Once you have set up your personal space, Confluence users can reach it by clicking your name in the People Directory.

Creating your personal space

To set up your personal space, you require the 'Personal Space' permission which is assigned by a Confluence administrator from the Administration Console. Refer to the Security Overview and Global Permissions Overview topics or contact a Confluence administrator for more information.

To create your personal space,
1. Go to your name at the top of the page. (This is the 'User' menu. A dropdown list will appear when your cursor hovers over the 'User' menu.)

2. Select 'Create Personal Space' from the dropdown list. The 'Create Personal Space' view will open.

3. Enter a few details about your space:
   - Choose who can view content.
   - Choose who can contribute (create and edit) content.
   - Choose the Theme (look and feel) for your personal space.

4. Click the 'Create' button.

5. The 'Home' page for your new space is displayed.
   Note: Your home page will automatically contain any default space content as defined by your Confluence administrator.
Adding and changing content in your space

Now you can start adding pages to your personal space. You may also want to upload your photo.

Granting access to your space

When you created the space (see above), you made some preliminary decisions about who can view and contribute content to your space. You can change the permissions on your space at any time.

**Viewing all Spaces**

Once you login, the list of spaces you have permission to view is displayed on your Dashboard under the spaces section.

The list of spaces is displayed via meaningful tabs:

- **My Spaces**: Spaces you marked as your favourites.
- **Team Spaces**: Spaces pertaining to a team grouped together using team labels.
- **New**: New spaces added to the site in the last seven days.
- **All**: All the spaces on the site.

**Screenshot: Viewing Spaces**

<table>
<thead>
<tr>
<th>Spaces</th>
<th>My</th>
<th>Team</th>
<th>New (1)</th>
<th>All</th>
</tr>
</thead>
<tbody>
<tr>
<td>Confluence  (DOC)</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Confluence 1.4 User Guide (CONF14)</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Confluence 2.0 User Guide (CONF20)</td>
<td></td>
<td></td>

</tr>
<tr>
<td>Documentation Staging (DOCPRIV)</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Documentation Staging 2 (DOCPRIV2)</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- Additionally, a list of personal spaces is available via the People Directory icon on the Dashboard:

Go to the Dashboard from any page on your site simply by clicking the logo beside the page title or via the Breadcrumbs (the "you are here" path) located at the top of every page.

If you do not login, you will be treated as an 'anonymous user' and only those spaces to which an anonymous user has 'View' permission will be displayed on the Dashboard.

Permission to a space is granted by a space administrator. See Space permissions for more information.

**Handy Hint**

Use the Spaces List Macro to view the list of spaces from any other page in Confluence.
Viewing Space Activity

The Confluence Usage Tracking Plugin, which governs the Activity tab, is known to have performance issues on large installations. In Confluence 3.0, this plugin is disabled by default.

In Confluence version 2.3 and later, statistics on each space's activity are available. These include:

- How many pages and news posts have been viewed, added, edited
- Which content is the most popular (i.e. most frequently viewed)
- Which content is the most active (i.e. most frequently edited)
- Which people are the most active contributors/editors of content

To view a space's activity,

1. Go to the 'Browse Space' view. There are two ways to browse a space:
   - Go to a page in the space and select the option you want from the 'Browse' menu. The corresponding tab of the 'Browse Space' view will open.
   - Or click the icon next to the space name on the Dashboard. The 'Pages' tab of the 'Browse Space' view will open.
2. Go to the 'Activity' tab.

The number of pages and news posts that have been viewed, added and edited will be displayed graphically, showing trends over a period of time, e.g.:

*Screenshot: Number of viewed pages and news posts in a week*
Activity for week starting 31 December 2006

The top 10 most popular and most active pages and/or news posts will be listed, with a link to each, e.g.:

**Most popular content (Views)**

1. ![Confluence Documentation Home](link) (2262)
2. ![Set JAVA_HOME variable in Windows](link) (1180)
3. ![Confluence Installation Guide](link) (687)
4. ![Remote API Specification](link) (467)
5. ![User Macros](link) (436)
6. ![Installing Confluence Standalone](link) (385)
7. ![JIRA Issues Macro](link) (370)
8. ![Administrators Guide](link) (353)
9. ![Dynamic Tasklist Macro](link) (335)
10. ![Frequently Asked Questions](link) (320)

If your Confluence site is clustered, Space Activity will not be available.

Working with Attachments Overview

An attachment is any file that is included with your page. Images, Word documents, presentations, PDFs, multimedia and sound files are some examples of attachments.

Attachments are useful when you want to share information that exists in another file format.

In Confluence you can attach files to any page.

When a page you are viewing contains attachments, a small paperclip icon like this: [image] appears next to the page byline. Clicking the paperclip will take you to the ‘Attachments View’, where the full list of attachments is displayed.

Here is a summary of how to attachments work in Confluence.

- Go to the ‘Attachments’ view for the page. To do this:
  - Go to a page in the space, open the ‘Tools’ menu and select ‘Attachments’. The ‘Attachments’ view will open.
  - From this view, you can start attaching files to the page.
  - If you attach a file with the same name as an existing attachment, Confluence will create a new version of the existing attachment.
  - Once you have attached a file, you can then provide a link to it from a Confluence page.
  - When a user clicks on the link, the attachment will open, so long as the user has the software application needed to open the attachment.
  - In the case of image attachments, Confluence allows you to display attached images on the page.
  - When the attachment is an Office document, you will see a ‘View’ link next to the attachment on the Attachments view. Click the ‘View’ link to view the content of the Office document within Confluence. If you have an Office application installed, you will also be able to launch your Office editor from within Confluence. See Displaying an Office Document in Confluence and Working with the Office Connector.

Attaching Files to a Page

An attachment is any file that is included with your page. Images, word documents, presentations, PDFs, multimedia and sound files are some examples of attachments. Attachments are useful when you want to share information that exists in another file format. Read more in the Attachment Overview.

When you attach a file to a page, Confluence makes a copy of the file and stores it on the server. File attachments in Confluence are contained in the ‘Attachments’ view of a page.

To attach a file, you need the 'Create Attachments' permission which is assigned by a space administrator from the Space Administration screens. See Space Permissions or contact a space administrator for more information.

Tip: Attaching and linking files via the 'Insert Link' icon

This page tells you how to use the ‘Attachments’ view to attach a file to a page. You can also attach files via the ‘Insert Link’ icon as described in Linking to an Attachment.
Handy Hint

Changes you make to the original file after you've attached it don't affect the copy in Confluence. To update the content of the file, you will need to upload a new version.

Attaching files

To attach a file to a page,

Go to the 'Attachments' view for the page. To do this:

1. Go to a page in the space, open the 'Tools' menu and select 'Attachments'. The 'Attachments' view will open.
2. Click the 'Browse' button.
3. Browse through your files and select the file you'd like to attach.
4. Enter a description for the attachment in the 'Comment' text field (optional).
5. Click 'Attach more files' if required.

Attachment Versions

If you upload a file with the same name as an existing attachment, Confluence will rename the old file and maintain a version of it on the server. Read more about Attachment Versions and Viewing Attachment Details.

Attachment Information Icon

When a page you are viewing contains attachments, a small paperclip icon like this: ![Paperclip Icon] appears next to the page byline. Clicking the paperclip will take you to the 'Attachments View', where the full list of attachments is displayed.

Attachment Versions

An attachment is any file that is included with your page. Images, word documents, presentations, PDFs, multimedia and sound files are some examples of attachments. Attachments are useful when you want to share information that exists in another file format. Read more in the Attachment Overview.

To create a new version of an existing attachment, simply upload an attachment with the same filename.

The existing file will be kept as 'Version x', and can be accessed from the page's 'Attachments' view.

Screenshot: Attachment versions
Some additional notes:

- You cannot remove specific versions of an attachment — if you remove an attachment, all versions will be removed as well. (See feature request CONF-3079.)
- You cannot revert to a previous version of an attachment. (See feature request CONF-1943.)
- By default, attachments and their versions are stored in the `<confluence_home>/attachments` directory. (See Attachment Storage Configuration in the Administrator's Guide.) There is no limit to the number of attachments/versions, provided that there is enough disk space.

<td>Edit</td>
</tr>
</tbody>
</table>

On this page:
Usage with the Macro Browser

To insert the attachments macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'Insert' to put the macro into the page.

Once you've found the attachments macro, click 'Insert' to add it to your page.

Usage with the Wiki Markup Editor

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>{attachments}</td>
<td>Name</td>
</tr>
<tr>
<td>office1.jpg</td>
<td>94 kB</td>
</tr>
<tr>
<td>waterfall.jpg</td>
<td>1.27 MB</td>
</tr>
</tbody>
</table>

Parameters

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in **Bold** text, while their equivalents in wiki markup are indicated in *(bracketed)* text. If the latter is not shown, then in wiki markup, the parameter's name should be omitted and only its value should be added immediately after the colon symbol (:).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Filename Patterns <em>(patterns)</em></td>
<td>all</td>
<td>Specify which attachments to display using filename patterns.</td>
</tr>
<tr>
<td>Include Old Attachment Versions <em>(old)</em></td>
<td>false</td>
<td>Include old attachments versions in the list.</td>
</tr>
<tr>
<td>Sort By <em>(sortBy)</em></td>
<td>date</td>
<td>Specify the sort order for attachments. Valid values are &quot;date&quot;, &quot;size&quot; and &quot;name&quot;.</td>
</tr>
<tr>
<td>Allow Upload <em>(upload)</em></td>
<td>false</td>
<td>Adds functionality to allow the upload of new attachments.</td>
</tr>
</tbody>
</table>

Examples

1. Filter Attachments by File Name

Use a comma-separated list of regular expressions to specify the filenames of the attachments you want displayed.

```
{attachments:patterns=.*jpg,.*gif}
```

**Note**
The patterns are regular expressions, so to match a file suffix of 'jpg', use *.jpg, not *.jpeg.
Here's a detailed tutorial on regular expressions.

2. Include Old Attachments

An optional true/false value determines whether to show old versions of attachments. This is set to false by default.

Viewing the List of Attachments

When you view the page, you will see a list of attachments. When the attachment is an Office document, you will see a 'View' link as shown in the screen snippet below.

**Screenshot: List of attachments from 'Attachments' macro, including Office documents with 'View' link**

<table>
<thead>
<tr>
<th>Name</th>
<th>Size</th>
<th>Creator (Last Modifier)</th>
<th>Creation Date</th>
<th>Last Mod Date</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>document pdf</td>
<td>37 kB</td>
<td>Sarah Maddox Nov 03, 2008</td>
<td>Nov 03, 2008</td>
<td>Nov 03, 2008</td>
<td>Edit</td>
</tr>
<tr>
<td>spreadsheet xld</td>
<td>20 kB</td>
<td>Sarah Maddox Nov 03, 2008</td>
<td>Nov 03, 2008</td>
<td>Nov 03, 2008</td>
<td>Edit</td>
</tr>
<tr>
<td>document doc</td>
<td>27 kB</td>
<td>Sarah Maddox Nov 03, 2008</td>
<td>Nov 03, 2008</td>
<td>Nov 03, 2008</td>
<td>Edit</td>
</tr>
<tr>
<td>presentation.ppt</td>
<td>108 kB</td>
<td>Sarah Maddox Nov 03, 2008</td>
<td>Nov 03, 2008</td>
<td>Nov 03, 2008</td>
<td>Edit</td>
</tr>
</tbody>
</table>

Click the 'View' link to view the content of the Office document within Confluence. If you have an Office application installed, you will also be able to launch your Office editor from within Confluence. See Displaying an Office Document in Confluence and Working with the Office Connector.

Attachment Information Icon

When a page you are viewing contains attachments, a small paperclip icon like this: ![Paperclip Icon](image) appears next to the page byline. Clicking the paperclip will take you to the 'Attachments View', where the full list of attachments is displayed.

Editing Attachment Details

To edit an attachment’s details, you need ‘Create Attachments’ permission which is assigned by a space administrator from the Space Administration screens. See Space Permissions or contact a space administrator for more information.

**To edit the details of an attachment,**

1. Go to the page that contains the attachment.
2. Go to the ‘Attachments’ view for the page. To do this:
   - Go to a page in the space, open the ‘Tools’ menu and select ‘Attachments’. The ‘Attachments’ view will open.
3. Click the ‘Edit’ link beside the attachment. This will bring up a new screen.
4. Make your changes:
   - **File Name** — Rename or modify the name of the attachment.
   - **New Comment** — Update the existing comment or enter a new comment.
   - **New Content Type** — Change the content type of the attachment by entering a valid Mime type.
   - **Page** — Move the attachment to another page.
   - **Update Links?** — Choose whether you want to update links to the attachment when new versions are uploaded.
5. Click ‘OK’.

Working with Attachments

Take me back to Confluence User Guide

**Embedding Multimedia Content**

You can embed multimedia files into a Confluence page as easily as you can an image. Confluence supports these formats:

- Flash (.swf)
- Quicktime movies (.mov)
- Windows Media (.wma, .wmv)
- Real Media (.rm, .ram)
- MP3 files (.mp3)
- AVI files (.avi) You may need to enable an avi decoder within your browser

You can use other types of files, but you may need to specify the ‘classid’, ‘codebase’ and ‘pluginspage’ properties so that your web browser can recognise the file type, as described below.
For security reasons, files located on remote servers are not permitted.

Other ways to display external and internal objects
Take a look at the Office Connector for embedding Office documents and presentations onto your Confluence page. Or try the Widget Connector for displaying live content from external sites.

On this page:
- Basic Usage
- Specifying File Type and Other Properties
- Troubleshooting

Basic Usage
Attach the file to the page. You can then include it as you would include an image, like this:

```
!filename.mov!
```

Specifying File Type and Other Properties
Define the properties of the embedded object using a comma-separated list of properties. For example:

```
!filename.mov|height=800,width=600,id=media!
```

If the file does not have a meaningful extension, specify the mime type like this:

```
!filename|type=image/jpeg!
```

To play .avi files, you need to specify the dimensions and type. For example, to play a test.avi file:

```
!test.avi|height=200,width=200,id=media!
```

Advanced styling via CSS
By default, each embedded object is wrapped in a div tag. If you wish to style the div and its contents, override the embeddedObject CSS class. Specifying an ID as a property also allows you to style different embedded objects differently. CSS class names in the format embeddedObject-ID are used.

Troubleshooting
- If you get an error 'Unable to embed content of type application/octet-stream', this means the mime-type is not being correctly recognised. You can add a type parameter to the macro code to override the auto-detected mime-type. See above for an example.
- For security reasons, files located on remote servers are not permitted.

Embedding PowerPoint Presentations in a Page
Below are some ideas on how your wiki page can include information from a Microsoft PowerPoint presentation.

On this page:
- Option 1 - Office Connector for Confluence
- Option 2 - Gallery or Slide Show of JPEG or PNG Images
- Option 3 - Convert PowerPoint to HTML
**Option 1 — Office Connector for Confluence**

The Office Connector provides the most straightforward way to display PowerPoint slides.

To attach and display a PowerPoint presentation in Confluence,

1. Attach the presentation to a Confluence page:
   - View the Confluence page where you want to display your presentation.
   - Open the 'Tools' menu and select 'Attachments'.
   - Browse for your PowerPoint presentation and upload it to the Confluence page.
   You will find detailed instructions in Attaching Files to a Page.

2. Now you can display the document embedded into the Confluence page, via View File macro. The basic syntax is:

   ```
   {viewfile:myPresentation.ppt}
   ```

   Refer to the detailed instructions on the View File macro.

The Office Connector is shipped with Confluence 2.10 and later. The Office Connector plugin is supported for Confluence versions 2.8.0 and later.

**Option 2 — Gallery or Slide Show of JPEG or PNG Images**

1. Convert your PowerPoint pages into JPEG or PNG images, using 'save as' from PowerPoint (slide1.jpg, slide2.jpg...).
2. Upload the image files as attachments to your Confluence page. To upload in bulk, use the WebDAV plugin.
3. Use the Gallery macro or the Slideshow plugin to render the images as a slide show in Confluence.

✅ Optionally, you could create a page template or a user macro that uses the Slideshow plugin, so that you do not have to code this into the wiki page each time you create a new show.

The Slideshow plugin is not supported by Atlassian. Please weigh up your options carefully before deciding which way to go.

**Option 3 — Convert PowerPoint to HTML**

You can convert the PowerPoint file to web page format and embed the page inside your Confluence document.

⚠️ If you accept page edits or comments from untrustworthy users, you should not attempt this process, due to a risk of malicious user attacks via the html-include macro.

1. Review the risks associated with enabling the html-include macro here.
2. If you decide to proceed, follow the instructions to enable embedded HTML pages using the macro.
3. Select an PowerPoint converter. There are at least two applications that can convert PPT to HTML:
   - Producer for PowerPoint.
   - If you do not have the PowerPoint application on your machine, you can use the Internet Assistant for Powerpoint instead.
4. Download and install your chosen converter.
5. Follow the converter documentation to perform the HTML conversion. An Internet Assistant conversion guide can be found here. The conversion process will create a small collection of HTML pages. Each slide will have its own page, plus an index page with buttons to let you switch between slide pages.
6. If you wish, you can test the HTML presentation now by loading the index page in your browser.
7. Place the HTML files into their own directory, named uniquely by the title of your presentation.
8. Find a suitable location to host these files within your web server. Confluence hosts all files within the `<my-install-directory>/confluence/` directory, so a good example location for Confluence standalone users is to go to `<my-install-directory>/confluence/pages/` and create a subdirectory called `powerpoint`.
9. Move the HTML directory into the PowerPoint folder, e.g. `<my-install-directory>/confluence/pages/powerpoint/` containing `index.html`, `slide01.html`, etc... or similar.
10. Edit or create the page where you wish to embed the PowerPoint presentation. In wiki markup, insert the html-include macro pointing to the index page of your slides. Remember that URLs are case sensitive. For example
11. Save the page. The index page to your slides should now appear.

---

**Finding an Attachment**

An attachment is any file that is included with your page. Images, word documents, presentations, PDFs, multimedia and sound files are some examples of attachments. Attachments are useful when you want to share information that exists in another file format. Read more in the Attachment Overview.

To find an attachment, you can search the list of attachments in a space or the attachments on a specific page.

**To find an attachment associated with a space,**

1. Go to the 'Space Attachments' view for the current space. To do this:
   - Go to a page in the space, open the 'Browse' menu and select 'Attachments'. The 'Space Attachments' view will open.
   - This will display a list of all attachments in the space.
2. You can choose to view only files of a particular type:
   - Type the last part of the file name in the 'Filter By File Extension' text field. For example, enter 'gif' to see only image files of the GIF format.
   - Click 'Go'.
3. You can view the attachment itself or the page to which it is attached by clicking on the corresponding link.

**Screenshot : Space Attachments**

<table>
<thead>
<tr>
<th>Name</th>
<th>Size</th>
<th>Creator (Last Modified)</th>
<th>Creation Date</th>
<th>Last Mod. Date</th>
<th>Attached To</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.png</td>
<td>30 kb</td>
<td>Kevin Tran</td>
<td>Jul 04, 2007</td>
<td>Jul 04, 2007</td>
<td>Connecting to HSQLDB using DBVisualizer</td>
</tr>
</tbody>
</table>

**To find attachments associated with a page,**

1. Go to the 'Attachments' view for the page. To do this:
   - Go to a page in the space, open the 'Tools' menu and select 'Attachments'. The 'Attachments' view will open.
2. This will display a list of all files attached to the page.
3. Click a link to view the corresponding attachment.

**Screenshot : Page Attachments**
**Handy Hint**
If you know the title of an attachment, you might find it faster by doing a Quick Search.

**RELATED TOPICS**

**Linking to Attachments**

Once you have attached a file to a page, you can easily provide a link to it from the page.

This page tells you how to use Wiki Markup to link to an attachment. You can also use the Rich Text editor to link to an attachment.

Images are a special form of attachment. Read about displaying images on a page.

### Linking to an Attachment on a Page

You can link to images and other types of attachments like this:

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>![Linking to attachments.pdf]</td>
<td>Linking to attachments.pdf</td>
</tr>
<tr>
<td>![PDF document about linking to attachments][1] ![Linking to attachments.pdf]</td>
<td>PDF document about linking to attachments</td>
</tr>
</tbody>
</table>

Where:

'Linking to attachments.pdf' is the name of the file you want to link to.

### Linking to an Attachment on Another Page

You can link to any attachment on your Confluence site using the following syntax:

**Attached to another page in the same space:**

```
[pagetitle"attachment.ext]
```

**Attached to another page in another space:**

```
[spacekey:pagetitle"attachment.ext]
```

### Adding Link Aliases and Tips

Optionally, you can:

- use an alias to refer to the attachment.
- provide a link tip for the link.

**Example 1:**

---

1. ![Linking to attachments.pdf](attachment.ext)
2. ![PDF document about linking to attachments][1] ![Linking to attachments.pdf]
Example 2:

```
[link alias|spacekey:pagetitle^attachment.ext|link tip]
```

**Linking to a Specific Version of an Attachment**

The link format described above will always link to the current version of the attachment.

If you want to link to a particular version of an attachment you will need to use the full URL. For example:

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>[Version 1</td>
<td><a href="http://confluence.atlassian.com/download/attachments/139515/Linking+to+attachments.pdf?version=1">http://confluence.atlassian.com/download/attachments/139515/Linking+to+attachments.pdf?version=1</a></td>
</tr>
</tbody>
</table>

** RELATED TOPICS **

**Moving an Attachment**

You can move an attachment from its current location to any page within the site.

To move an attachment, you need the following permissions:

- Edit page permission on the page where the attachment currently exists.
- Create attachment permission on the space into which you are moving the attachment.

Space permissions are assigned by a space administrator from the Space Administration screens. See Space permissions or contact a space administrator for more information.

**To move an attachment,**

1. Go to the page that contains the attachment.
2. Go to the 'Tools' menu and select 'Attachments'.
3. Click the 'Edit' link beside the attachment. This will bring up a new screen, where you can:
   - Rename the attachment in the 'File Name' text field (optional).
   - Update the existing comment or enter a new comment in the 'New Comment' text field (optional).
4. Select the page to which you want to move the attachment by clicking on the Choose a Page icon. A pop-up screen allows you to locate pages anywhere within the site.
5. Under 'Update Links', select 'Yes' to ensure that any links to this attachment are maintained when you move it. Only select 'No' if you are sure that there are no links to this attachment within the current space.
6. Click 'OK'.

**Screenshot : Moving an attachment**
Choose a Page

The 'Choose a Page' window allows you to locate a page in your Confluence site. The window appears when you are moving an attachment.

To choose a page,

1. Click the page picker icon to bring up the 'Choose a Page' window. You will see the following tabs:
   - **Search**: Allows you to search for your page in all Confluence spaces.
   - **History**: Displays a list of pages recently visited by you.
   - **Recently Modified**: Displays pages most recently modified by you.
   - **Referring Pages**: Displays a list of all pages that refer to the current page.

2. Select the required page from the list of pages in one of the tabs.

Viewing Attachment Details

An attachment is any file that is included with your page. Images, word documents, presentations, PDFs, multimedia and sound files are some examples of attachments. Read more about attachments in the Attachments Overview.

There are two places where you can view attachment details.

- View the attachments in a space — this will show the files/images attached to all pages in the space.
- View the attachments for a specific page.

On this page:
- Viewing Attachments in a Space
- Viewing Attachments on a Page
- Attachment Details
- Viewing Attached Office Documents
- Attachment Information Icon

Viewing Attachments in a Space
To view the attachments associated with a space,

1. Go to the ‘Space Attachments’ view for the current space. To do this:
   - Go to a page in the space, open the ‘Browse’ menu and select ‘Attachments’. The ‘Space Attachments’ view will open.

   This will display a list of all the attachments in the space. Each attachment is displayed along with its details and the page it is attached to.

2. You can choose to view only files of a particular type:
   - Type the last part of the file name in the ‘Filter By File Extension’ text field. For example, enter ‘gif’ to see only image files of the GIF format.
   - Click ‘Go’.

Screenshot 1: Space Attachment Details

Viewing Attachments on a Page

To view the attachments associated with a page,

1. Go to the page.

2. Go to the ‘Attachments’ view for the page. To do this:
   - Go to a page in the space, open the ‘Tools’ menu and select ‘Attachments’. The ‘Attachments’ view will open.

   This will display a list of all the attachments in the page along with their details. For each attachment, links are also provided to edit the attachment’s details and to delete the attachment.

Screenshot 2: Page Attachment Details

In the screenshot above, A. D. Ministrator created the first version of harbour.jpg. John Smith uploaded the second version and Jane Smith added a comment (and is listed as the last modifier).

Attachment Details

The attachment views show the following fields. (The page view shows a different subset of fields from the space view.)

- **Name** is the name of the attached file.
- **Size** tells you how much space the attachment takes up. You can sort by size by clicking the column title.
- **Creator** is the user who attached this file. The person who uploaded each new version of a file will be acknowledged as the creator of that version. Clicking on the link takes you to their profile.
- **Last modifier** is the user who last modified the file. Actions that qualify as a modification include renaming, moving, adding/updating a comment or updating the content type.
- **Creation Date** is the date the file was attached. You can sort by date by clicking the column title.
- **Last Mod. Date** is the date the file was last modified. Please refer to definition of Last Modifier for a list of actions that qualify as a modification.
**Viewing Attached Office Documents**

When the attachment is an Office document, you will see a 'View' link as shown in the screen snippet below.

**Screenshot 3: Page attachments including Office documents with 'View' link**

Click the 'View' link to view the content of the Office document within Confluence. If you have an Office application installed, you will also be able to launch your Office editor from within Confluence. See Displaying an Office Document in Confluence and Working with the Office Connector.

**Attachment Information Icon**

When a page you are viewing contains attachments, a small paperclip icon like this: ![Paperclip Icon] appears next to the page byline. Clicking the paperclip will take you to the 'Attachments View', where the full list of attachments is displayed.

- Gallery Macro  
- Embedding PowerPoint Presentations in a Page

**RELATED TOPICS**

Working with Attachments

Take me back to Confluence User Guide

**Displaying an Image**

You can display an image from either a file attached to the Confluence page, or from another location.

This page shows you how to display an image using Confluence Notation, also known as Wiki Markup.
Using the 'Insert Image' icon

Instead of Wiki Markup, you can use the 'Insert Image' icon. This behaves in a similar way for both the Wiki Markup and the Rich Text editor, as described in Inserting an image.

To follow the instructions below, you need to edit in 'Wiki Markup' mode. Put an exclamation point before and after the image link.

Displaying an image from a remote location

You need to know the URL from which the image can be linked.

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
</table>

Displaying an image attached to a page

- First, attach the image to the page.
- Now you can display the attached image:

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>!fish.gif!</td>
<td><img src="fish.gif" alt="Fish Image" /></td>
</tr>
</tbody>
</table>

Displaying an image attached to another Confluence page

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>!Space attachments directory^fish.gif!</td>
<td><img src="fish.gif" alt="Fish Image" /></td>
</tr>
</tbody>
</table>

Where 'Space Attachments Directory' is the name of the page containing the attachment.

Usage example

What if you want to upload an image only once, but display it on many pages?

- Attach the image to a page, such as our page called the 'Space attachments directory'.
- Link to the uploaded image using the syntax described above.

To view the image, the user needs to have view permission for the page to which it is attached.

Displaying an image attached to page in a difference space

<table>
<thead>
<tr>
<th>What you need to type</th>
</tr>
</thead>
<tbody>
<tr>
<td>!SPACE:my page^myimg.jpg!</td>
</tr>
</tbody>
</table>

Formatting an image
Displaying alternative text

Use the HTML `title` attribute to specify text which is displayed when the pointer is hovering over an image. Use the `alt` attribute to specify alternative text to be included in the HTML code.

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>![fish.gif</td>
<td>title=&quot;I am a fish&quot;]!</td>
</tr>
<tr>
<td>![fish.gif</td>
<td>alt=&quot;I am a fish&quot;]!</td>
</tr>
</tbody>
</table>

**HTML image attributes**

For any image, you can also specify attributes of the HTML image tag as a comma-separated list of name=value pairs. Available image tags include:

- `align` — available values are 'left', 'right', 'bottom', 'center', 'top'.
- `border` — specify the width of the border (in pixels).
- `bordercolor` — use this with the above `border` tag to specify the colour of the image border. Specify the colours by name or by hex value. See more information about web colours. (Available with Confluence 2.6.2 and later.)
- `hspace` — specify the amount of whitespace to be inserted to the left and right of the image (in pixels).
- `vspace` — specify the amount of whitespace to be inserted above and below the image (in pixels).
- `width` — specify the width of the image (in pixels). This will override the natural width of the image.
- `height` — specify the height of the image (in pixels). This will override the natural height of the image.
- `title` — specify alternative text for the image, which is displayed when the pointer hovers over the image
- `alt` — specify alternative text, which is included in the HTML code. This text is retrievable via search, and contributes to accessibility of the page for text-only viewing.

**Image File Formats**

Confluence allows you to attach image files of any format to a page. However, your ability to display them depends on the image file formats supported by the browser you are using.

Confluence supports the following image formats for its Thumbnail and Gallery macros:

- gif
- jpeg
- png

The bmp format is not supported.

**RELATED TOPICS**

- Displaying an Image
- Displaying a Thumbnail Image
- Gallery Macro

Take me back to Confluence User Guide
Displaying a Thumbnail Image

You can display an image on a Confluence page as a thumbnail, such that when a user clicks on the thumbnail image, a new window will pop up showing the full-sized image.

This page shows you how to display a thumbnail of an image using Confluence Wiki Markup Notation. To do this, you need to add the 'thumbnail' attribute to the notation used for displaying an image to a Confluence page. This resizes the original image proportionately, allowing for a maximum height or width of 200 pixels by default.

Please Note:

- Using the 'Insert Image' icon
  Instead of Wiki Markup, you can use the 'Insert Image' icon. This behaves in a similar way for both the Wiki Markup and the Rich Text editor, as described in Inserting an image.

- Setting the size of the thumbnails for your Confluence instance
  A Confluence Administrator can change the size of thumbnails via the Administration Console. This will also affect the images displayed by the Gallery macro.

- Image formats
  Confluence will only create thumbnails for these file formats: gif, jpg, and png. The bmp format is not supported.

- Image attributes
  The HTML attributes as described in Displaying an Image override the 'thumbnail' attribute.

### Thumbnail of image attached to this page

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
</table>
| ![waterfall.jpg](attachment)
| ![waterfall.jpg](attachment) |

'waterfall.jpg' is the name of your image.

### Thumbnail of image attached to another Confluence page

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
</table>
| ![Space attachments directory^fish.gif](attachment)
| ![Space attachments directory^fish.gif](attachment) |

'Space attachments directory' is the name of the other page.

### Specifying the default alternative text for a thumbnail image

You can specify a comment for an attached image, which will be used as the default alternative text when the image is displayed as a thumbnail.

**Attaching a new image file** - Enter the relevant comment in the Comment box provided when you attach the file to the page.

**Applying a comment to existing image attachment** - The 'Attachments' tab of the page displays all attached files. Click 'Edit' in the row of the attached image entry. In the 'New Comment' text entry field, enter the default alternative text that should be displayed whenever a thumbnail of that image appears.

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
</table>
Thumbnail and Gallery Example

**Thumbnail**

You can have Confluence automatically make a thumbnail of any inline image that is attached to a page. Clicking on the image will pop up a window containing the full-size image.

![waterfall.jpg](attachment://waterfall.jpg?thumbnail)

For more information, see Displaying a Thumbnail Image.

**Image Gallery**

The `{gallery}` macro creates a gallery of thumbnails from all of the images that are attached to a page, titling each with the appropriate attachment comment.

```
{gallery:title=Some Confluence Features, and a Waterfall}
```

*Some Confluence Features, and a Waterfall*
1. Go to the page which contains the gallery of images. See Screenshot 1 below.

2. Click an image. The slide show will start by zooming in on the image you have clicked. See Screenshot 2 below.

3. Use one of the following methods to move to the next or previous image:
   - Move your mouse cursor over the image until an arrow appears on left or right of the image. Screenshot 2 below shows the arrow on the right. Click the arrow to move to the next or previous image.
   - Or press the left- and right-arrow keys on your keyboard.

4. Use one of the following methods to close the slide show:
   - Click the cross at top right of the image.
   - Or press the Escape key on your keyboard.
   - Or click somewhere on the browser window, outside the zoomed-in image.

Screenshot 2: Viewing the gallery as a slide show
Confluence tries to encourage linking by making it as simple as possible. You can link to content anywhere within Confluence or an external site just as easily, using the same syntax. Confluence also gives you the flexibility to do some pretty complicated things with links.

You can create links to and from any of the editable content on the site:

- Pages in the same space, in another space, or outside Confluence
- News items
- Comments
- User profiles or personal spaces
- Mail messages
- Attachments

You can also use a Confluence link to:

- Create a new mail message.
Links in Confluence are always denoted by square brackets. Whenever you place text between square brackets, Confluence recognises it as a link.

**Handy Hints**

- Links in Confluence will not break even when you rename pages or move them between spaces on your site!
- Looking for link type not shown above? You might find a plugin can help you.
- Your Confluence administrator can configure Confluence to display icons next to each link, distinguishing external links, user links and email links.

**RELATED TOPICS**

- Rich Text—Creating and removing a link
- Changing the Title of a Link
- Working with Anchors
- CamelCase linking
- Trackback
- Linking to Confluence Pages from Outside Confluence

Take me back to Confluence User Guide

**CamelCase linking**

CamelCase is a form of markup used in many wikis where words capitalized and compounded together without spaces LikeThis, are used to create links.

By default, CamelCasing is not enabled in Confluence. However, a site administrator can turn on CamelCasing from the Administration Console. For more information about activating CamelCase Links, see Enabling CamelCase Linking in the Administrators Guide.

To link to a page in the same space using CamelCase linking

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelCasePage</td>
<td>CamelCasePage</td>
</tr>
</tbody>
</table>

where:

`'CamelCasePage'` is the name of the page you want to link to.

To link to a page you intend to create later (undefined page) using CamelCase linking

Confluence allows you to create links first and add add content to pages later. This type of a link is an undefined link and is indicated with the plus sign. Clicking on the link will bring up a screen where you can add content for the page.

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>NonExistentPage</td>
<td>[NonExistentPage]</td>
</tr>
</tbody>
</table>

where:

`'NonExistentPage'` is the title of the page you intend to create later.

To ensure a CamelCase word does not become a link

(Confluence 2.1.3 or later)

Sometimes you may wish to use a CamelCase word in a page, but do not want it to be drawn as a link. You can accomplish this using the {nolink} macro:

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>{nolink:SomeWord}</td>
<td>SomeWord</td>
</tr>
<tr>
<td>{nl:SomeWord}</td>
<td>SomeWord</td>
</tr>
</tbody>
</table>

{nolink} and {nl} do the same thing, just use whichever you find more convenient.

The {nolink} and {nl} macros are only available in Confluence 2.1.3 or later. In versions of Confluence prior to 2.1.3, there is no way to prevent a CamelCase word from becoming a link short of disabling CamelCase linking across the entire Confluence site.
CamelCasePage

This page is a demonstration of a page that can be linked to using CamelCase linking. You can find more information on the subject here.

Changing the Title of a Link

Sometimes, you may need to change the default labels for links if they are not particularly informative or attractive, and especially if you are including the links in the middle of your own text.

To change the title of a link,

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>[the current release notes</td>
<td>Sample Release Notes]</td>
</tr>
</tbody>
</table>

Where:

- 'the current release notes' is your new label.
- 'Sample Release Notes' is the name of the page you want to link to.

Example: Changing the title of a news item

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>[an article on the subject</td>
<td>2007/06/25/Sample News]</td>
</tr>
</tbody>
</table>

Where:

- 'an article on the subject' is how you want to refer to the news item
- '2005/08/26' is the date the news item was published.
- 'Sample News' is the actual title of the news item

Example: Combining inter-space links and labelled links

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
</table>

Where:

- 'User Guide for a previous version of Confluence' is your label.
- 'CONF27' is the space key of the space the page you want to link to is located.
- 'Confluence 2.7 User Guide' is the name of the page in that space.

Sample Release Notes

Start of release notes content

End of release notes content

**Linking an Image**

This page tells you how to link an image to another page or URL. When the user clicks the image, they will jump to the linked page. You can also read the full instructions on attaching a file to a page and displaying an image on a page.

To link an image to another page, you will embed the `image` markup inside the `linking markup`.

### To add a link from an image on a page.

The syntax below will display the attached image called 'dochome.gif' and will also link the displayed image to the 'Confluence Documentation Home' page. So when a user clicks the image, they will go to the linked page.

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>![dochome.gif](Confluence Documentation Home)</td>
<td>![Confluence Documentation Home](Confluence Documentation Home)</td>
</tr>
</tbody>
</table>

### To add a link from an image attached to another page.

The syntax below will display the image called 'fish.gif', which is attached to the page called 'Displaying an image'. The syntax will also link the displayed image to the home page of the 'DOC' space. So when a user clicks the image, they will go to the linked page.

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="" alt="Displaying an Image" /></td>
<td><img src="" alt="DOC:Displaying an Image" /></td>
</tr>
</tbody>
</table>

ℹ️ The colon in the example is used to specify the space key ('DOC'). The page name then defaults to the home page for the space.

**Linking to Confluence Pages from Outside Confluence**

Sometimes you may want to link to a Confluence page from outside Confluence, e.g. from within another website or from within an email. In this case, you may want to link to a ‘permanent’ URL (also called a ‘permalink’), in case the name of the Confluence page changes.

(Note: if you are linking to a page from within another Confluence page, see Linking to Pages Within the Same Space or Linking to Pages in Another Space — links created in this way will be automatically updated if the page is renamed.)

### To link to a page’s ‘permanent’ URL,

1. Go to the 'Information' view for the page. To do this:
   - Go to a page in the space, open the 'Tools' menu and select 'Info'. The 'Information' view will open.
2. Copy the 'Tiny Link' and paste it into your email or external web page. This will create a link to the latest version of your Confluence page.

**RELATED TOPICS**

- Link to a Page within a Space

Take me back to Confluence User Guide
Linking to Pages in Another Space

This page tells you how to use Confluence Notation to link to a Confluence page. Instead, you can also use the Rich Text editor.

In Confluence notation, links are always denoted by square brackets. Whenever you place text between square brackets, Confluence recognizes it as a link.

💡 You can display your own text instead of the page name: Inside the square brackets, insert the required text followed by a vertical bar and then the page name. The second example shows this.

### To link to a page in a different space

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>[DS: Brief Overview of Confluence]</td>
<td>Brief Overview of Confluence</td>
</tr>
<tr>
<td>[Here's an overview</td>
<td>DS: Brief Overview of Confluence]</td>
</tr>
</tbody>
</table>

where:

'DS' is the space key of the space you are linking to, in this instance, the Demonstration Space.

'Confluence Overview' is the name of the page in the space, 'DS'.

---

### To link to the homepage of another space

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>[DS:]</td>
<td>Demonstration Space</td>
</tr>
<tr>
<td>[demo home page</td>
<td>DS:]</td>
</tr>
</tbody>
</table>

where:

'DS' is the space key of the space you are linking to, in this instance, the Demonstration Space.

💡 The space key is the short name displayed in parentheses beside each space name on the dashboard, and in various other places across the site.

### Handy Hint

You can also create a link to any Confluence page by clicking 'Insert Link' when you are in the 'Edit' mode of a page. A pop-screen allows you to select pages from anywhere within Confluence. Selecting a page creates a link to that page.

---

Linking to Pages Within the Same Space

This page tells you how to use Wiki Markup to link to a Confluence page from within another Confluence page. Instead of Wiki Markup, you can use the Rich Text editor.

### Linking to a Confluence Page

In Wiki Markup, links are denoted by square brackets. Whenever you place text between square brackets, Confluence recognises it as a link.

💡 You can display your own text instead of the page name: Inside the square brackets, insert the required text followed by a vertical bar and then the page name. The second example below shows this.

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
</table>

In the above examples, 'Confluence User Guide' is the name of the page you want to link to.
Using an Undefined Link to Create a Page

In Confluence, you can add a link which points to a page that you intend to create later. You might also use such a link to prompt other Confluence users to create pages. This type of link is called an undefined link.

To add an undefined link for later creation of a page,

1. Add a link, specifying the name of a page which does not exist. See example below.
2. Save the page which contains the undefined link. Confluence indicates undefined links by colouring them red.
3. When you (or another user) click on the link, the 'Add Page' screen appears.
4. You can then follow the steps outlined above to enter the page name, add content and save the page.

Here is an example of an undefined link:

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>[Link to new page]</td>
<td>[Link to new page]</td>
</tr>
</tbody>
</table>

You can also create a link to any Confluence page by clicking 'Insert Link' when you are editing a page. A popup screen allows you to select pages from anywhere within Confluence. Selecting a page creates a link to that page.

Linking to Personal User Spaces and User Profiles

You need to edit in 'Wiki Markup' mode to create a link to a user's personal space (or user profile).

You can link to a user's personal space (or user profile) easily if you know their username.

To link to a user's personal space,

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>~username</td>
<td>username</td>
</tr>
</tbody>
</table>

If the user does not have a personal space, then the link will go to their user profile.

RELATED TOPICS

- User Profile Overview

Take me back to Confluence User Guide

Linking to Web Pages

This page tells you how to use Confluence Notation to link to a web page. Instead, you can also use the Rich Text editor.

In Confluence notation, links are always denoted by square brackets. Whenever you place text between square brackets, Confluence recognizes it as a link.

You can display your own text instead of the URL: Inside the square brackets, insert the required text followed by a vertical bar and then the URL. The second example shows this.

To link to a web page outside Confluence,

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
</table>
Where:

'http://www.atlassian.com/software/confluence' is the URL that you want to link to.

Confluence will also try to find URLs within the text of the page and convert them into links, but it may have trouble separating the link from its surrounding text, especially when punctuation is involved. Putting the link inside square brackets will ensure that it is interpreted the right way.

**RELATED TOPICS**

Working with Links Overview

Take me back to Confluence User Guide

**Trackback**

Trackback is a mechanism by which two sites can stay informed each time one site refers to the other by means of trackback 'pings'.

In Confluence, Trackback is enabled by a [site administrator](http://www.atlassian.com/software/confluence) from the Administration Console. When Trackback is enabled, any time you link to an external webpage that supports Trackback Autodiscovery, Confluence will send a Trackback ping to that page to inform it that it has been linked to.

Confluence pages also support Trackback Autodiscovery, and when Trackback is enabled can receive trackback pings sent by other sites.

**To see who has sent a Trackback ping to a Confluence page,**

1. Go to the page.
2. Go to the 'Information' view for the page. To do this:
   * Go to a page in the space, open the 'Tools' menu and select 'Info'. The 'Information' view will open.
3. Any Trackback pings the page has received will be listed under the page's **Incoming Links**

See more information about the Information View.

**Using a link to create a new mail message**

You can insert the HTML 'mailto' tag inside a Confluence link using 'Wiki Markup' as shown below.

💡 You can display your own text instead of the 'mailto' tag: Inside the square brackets, insert the required text followed by a vertical bar and then the 'mailto' tag. The second example shows this.

**Examples**

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>[<a href="mailto:jsmith@non.existent.corp.com">mailto:jsmith@non.existent.corp.com</a>]</td>
<td><a href="mailto:jsmith@non.existent.corp.com">jsmith@non.existent.corp.com</a></td>
</tr>
<tr>
<td>[Sales</td>
<td><a href="mailto:jsmith@non.existent.corp.com">mailto:jsmith@non.existent.corp.com</a>]</td>
</tr>
</tbody>
</table>

Working with Links Overview
Linking to Mail

Take me back to Confluence User Guide
Working with Anchors

The Anchor Macro allows you to link to specific parts of a page. Anchor links can be especially useful when navigating between sections of a long document or when you want to link to a segment of a page and not to the page as a whole.

Anchors are invisible to the reader when the page is rendered.

Anchors are made up of two parts:

- The link
- The content to which you are linking.

On this page:

- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
- Parameters
- Examples

Usage with the Macro Browser

To insert the anchor macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'Insert' to put the macro into the page.

Once you've found the anchor macro, click 'Insert' to add it to your page.

Usage with the Wiki Markup Editor

The following code creates an anchor called "here", but you can substitute this with whatever name you like.

```
{anchor:here}
```

Once an anchor is in the page, you can link to it by putting #here (or whatever anchor name you choose) at the end of a link pointing to that page.

Parameters

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in **Bold** text, while their equivalents in wiki markup are indicated in *(bracketed)* text. If the latter is not shown, then in wiki markup, the parameter's name should be omitted and only its value should be added immediately after the colon symbol (:).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anchor Name</td>
<td>None; name must be supplied</td>
<td>This is the name of the anchor that you will link to.</td>
</tr>
</tbody>
</table>

Examples

In the next example, there are two anchors in this page called "top" and "bottom", which you can link to like so:

```
[#top]
[#bottom]
```

These links come out like this: top bottom.

More examples follow.

Linking to an anchor in the same page
Linking to an anchor in another page

```
[nameofpage#anchorname]
```

Linking to an anchor in a page in another space

```
[spacekey:nameofpage#anchorname]
```

Linking to headings

Confluence treats all headings as anchors. So you don't have to place an anchor but simply link to it like this:

```
[#textofheading]
```

**Warning**

Page titles and links to other spaces can be combined with anchors and attachments, but you can't use attachments and anchors in the same link.

Note that if you are adding an anchor to the site welcome message, it must be to another page. Internal-only links such as (anchor:bottom) will not render.

**RELATED TOPICS**

Working with Links Overview

Take me back to the Confluence User Guide.

**Working with Labels Overview**

Labels are user-defined tag words that can be assigned to pages and spaces. You can use labels to categorise, identify or bookmark content in Confluence.

For example, you can assign the label 'accounting' to all accounts-related pages on the site. You can then browse all pages with the label 'accounting' in an individual space or across the site, do a search based on it, and even use it to filter information when you subscribe to a Confluence RSS feed.

Because labels are user-defined, you can add any word (or even make up your own) that helps you identify the content in the site.

Labels can be added or removed without affecting the page content.

There are two different types of labels:

- **Global labels** — see Adding a Global Label. A global label is available to all users across the site. Once a global label is added, any user with permission to view a page can also view its labels. Any user with permission to edit a page can add a global label to a page.
- **Personal labels** — see Adding a Personal Label. A personal label is only available to the user that created it. Any user with 'view' permission can add a personal label to a page. The personal labels start with 'my:'.

The following screenshot shows the labels at the bottom of the page's content:
Here are some of the advantages of using labels:

- Labels are user-defined which means that you decide what information is relevant to you and how you are going to label it.
- You can group pages without having to restructure the site.
- Labels are easy to add and edit, and do not affect the actual content of the page.
- You can use labels to filter information during a search.
- You can add as many labels as you like to a page.
- The RSS feed builder allows you to create a news feed based on labels.

Take me back to Confluence User Guide

**Adding a Global Label**

Any user with 'edit' permission for a page can add a global label to it.

To add a global label,

1. View the page. If the page already has labels, these will be listed at the bottom of the page below the page content.
2. Click the 'Add Labels' or the 'Edit' link beside the list of labels.
3. An input field will open below the existing labels. If available, it will also show you a list of 'suggested labels'. These are the labels that you have used recently and the most popular labels in the space. Your personal labels will also appear here if you have used them frequently or recently. Check if you want to use any of the suggested labels. Click a label to add it to the page.
4. If you want to add a new label, simply type it in and click 'Add'. As you type, the drop-down field will display the label closest to the word you are typing. It is possible another user may have added the same label or a similar label which you can select and reuse.
5. Click 'Done'.

```plaintext

Confluence Overview

**Labels**
- Installable example, admin, my stuff

### Children (2)
- Hide Children
- View in Hierarchy
- Add Child Page

- Page using Search Macro
- Sample Child Page

---

 nuts:cheese
Labels are always in lowercase. Even if you use uppercase characters, Confluence will convert these to lowercase when it adds the label.

Screenshot: Adding a Label

**Labels** Done

Enter labels to add to this page:

| Suggested labels: installation keys fisheye fun new to crucible festival year charity foundation |

Looking for a label? Just start typing.

**RELATED TOPICS**

- Adding a Personal Label
- Removing a label from a page
- Adding a Space Label
- Adding a Team Label

**Adding a Personal Label**

This page tells you about personal labels. You can also read about global labels.

You can use personal labels to mark content that you personally are interested in.

Any user with 'view' permission can add a personal label. Personal labels are visible only to the user who created them. To differentiate them from global labels, personal labels include the prefix 'my:' in the label name.

You can view your personal labels from your user profile.

Here are some examples of personal labels:

- my:sales
- my:stuff
- my:trivia

To add a personal label,

1. View the page which you want to label.
2. Click the 'Add Labels' or the 'Edit' link beside 'Labels'.
3. This will open up a form with an input field and a list of 'suggested labels'. An input field will open below the existing labels. If available, it will also show you a list of 'suggested labels'. These are the labels that you have used recently and the most popular labels in the space. Your personal labels will also appear here if you have used them frequently or recently. Check if you want to use any of the suggested labels. Click a label to add it to the page.
4. If you want to add a new personal label, type it in using the format 'my:label'. You can enter more than one label, separated by commas.
5. Click 'Add' to add the label.
6. Click 'Done' when you have finished, if you want to close the label input field.

**Labels are always lower case**

Even if you use uppercase characters, Confluence will convert these to lowercase when it adds the label.

Screenshot: Adding a Label
Adding a Space Label

To add a Space Label,

1. Go to the 'Space Admin' tab of the Browse Space view. To do this:
   - Go to a page in the space, open the 'Browse' menu and select 'Space Admin'. The 'Space Administration' view will open.

2. Click 'Edit Space Details'. This will take you to a new screen.

3. Click 'Edit Space Labels' in the left navigation frame. In the input field displayed under the heading 'Labels', type in your label and click 'Add'. A list of suggested labels is also displayed in the form. Click on the label to add it.

Screenshot: Adding a space label
For example, if you have one or more spaces on the site that the Sales team may be interested in, you can group all these spaces together under the label 'sales'.

On the Dashboard, you can then choose 'Sales' from the drop down menu under the 'Team' tab in the spaces list, and have only the list of spaces relevant to the Sales team displayed. The 'Recently Updated' section will also display content only from these spaces.

You will need to add the same label all the spaces you want to group together.

To add a Team Label,

1. Go to the 'Space Admin' tab of the Browse Space view. To do this:
   - Go to a page in the space, open the 'Browse' menu and select 'Space Admin'. The 'Space Administration' view will open.
   - 'Space Admin' is only displayed if you are a space administrator.
2. Click 'Edit Space Details'. This will take you to a new screen.
3. Click 'Edit Space Labels' in the left navigation frame.
4. In the input field displayed under 'Team Labels', type in your label and click 'Add'. A list of 'Suggested Labels' is also displayed in the form. Click on the label to add it.

**Screenshot: Adding a team label**

**Team Labels**

Team labels will appear in the drop down box inside the team tab on your dashboard. They can be used to group together related spaces for project teams.

No team labels added to this space.

**Screenshot: List of team related spaces on the dashboard**

**Spaces:**

- My
- Team
- All

A team label is used to group together a list of spaces relevant to a project team. You can display a team's spaces by selecting a label from below:

**View Spaces for Team:**

- **Confluence** (DOC)
- **Confluence 4.0 User Guide** (CONF4)
- **Confluence Community** (DOC)
- **Confluence Extensions** (CONTEXT)
- **Documentation Staging** (DOCPRIV)
Categorising Wiki Content Using Labels

Labels allow users to sub-categorise pages and reference content across multiple categories as well as Spaces.

**Label Example:**

For the purpose of this example, imagine we have a Space with pages of content on various type of vehicles.

**Vehicles Space**

(pages are in bold, while the labels are in blue)

- Cars **vehicle-type**
  - Toyota Prius **vehicle car**
  - Honda Civic **vehicle car**
  - Porshe Carrera **vehicle car**
- Motorbikes **vehicle-type**
  - Harley Davidson Sportster **vehicle motorbike**
  - Suzuki GSX-R **vehicle motorbike**

This page hierarchy can then be cross-categorised using labels, with pages referenced using the **Content by Label Macro**.

<table>
<thead>
<tr>
<th>If you want to list...</th>
<th>You would use the wiki markup:</th>
<th>These would be the pages that you would get:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vehicle types</td>
<td><code>{contentbylabel:label=vehicle-type}</code></td>
<td>Cars, Motorbikes</td>
</tr>
<tr>
<td>All vehicles</td>
<td><code>{contentbylabel:label=vehicle}</code></td>
<td>Toyota Prius, Honda Civic, Porshe Carrera, Harley Davidson Sportster, Suzuki GSX-R</td>
</tr>
<tr>
<td>All cars</td>
<td><code>{contentbylabel:label=car}</code></td>
<td>Toyota Prius, Honda Civic, Porshe Carrera</td>
</tr>
</tbody>
</table>

**RELATED TOPICS**

Working with Labels Overview

Working with Macros

Take me back to the Confluence User Guide.

**Content by Label Macro**

The **Content by Label macro** lists content which has been tagged with specific labels.

**On this page:**

- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
- Parameters
- Examples
  - 1. Show content from a specific space
  - 2. Show only results in current space
  - 3. Show results from all spaces
  - 4. Show only content of a specified type
  - 5. Do not show the labels in the results
  - 6. Do not show the space names in the results
  - 7. Display excerpts in the results
  - 8. Specify the maximum number of results to display
  - 9. Sort by modification date
  - 10. Change the sort order

**Usage with the Macro Browser**

To insert the content by label macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'insert' to put the macro into the page.

Once you've found the content by label macro, click 'insert' to add it to your page.

**Usage with the Wiki Markup Editor**

To display all pages with the label needs-fixing, use:

```
{contentbylabel:label=needs-fixing|showLabels=false|showSpace=false|maxResults=99|space=@self}
```

Below is a working example of the 'Content by Label' macro. In the example, we have restricted the display to 5 results. By default, Confluence lists all the labels for each result displayed. See the optional parameters below for more information.

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>{contentbylabel:label=needs-fixing</td>
<td>showLabels=false</td>
</tr>
</tbody>
</table>
Parameters

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in **Bold** text, while their equivalents in wiki markup are indicated in *(bracketed)* text. If the latter is not shown, then in wiki markup, the parameter's name should be omitted and only its value should be added immediately after the colon symbol ( : ).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>(author)</strong></td>
<td>None</td>
<td>Filter the results by author. The macro will display only the pages etc which are written or updated by the author(s) you specify here. You can specify one or more authors, separated by a comma.</td>
</tr>
<tr>
<td><strong>Label(s) (label) or (labels)</strong></td>
<td>None</td>
<td>This parameter is required. Use this parameter to filter the results by label. The macro will display only the pages etc which are tagged with the label(s) you specify here. You can specify one or more label values, separated by a comma or a space.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- To exclude content which matches a given label, put a minus sign (-) immediately in front of that label value. For example: if you specify a label value of <code>-badpage</code> you will get only content which is not labelled with 'badpage'.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- To indicate that the results <strong>must</strong> match a given label value, put a plus sign (+) immediately in front of that label value. For example: if you specify a label value of <code>+superpage,+goodpage</code> you will get only content which has at least two labels, being 'superpage' and 'goodpage'.</td>
</tr>
<tr>
<td><strong>Maximum Number of Pages (max) or (maxResults)</strong></td>
<td>15</td>
<td>Specify the maximum number of results to be displayed. Note that the results are sorted first, and then the maximum parameter is applied.</td>
</tr>
<tr>
<td><strong>(operator)</strong></td>
<td>OR</td>
<td>The operator to apply to the supplied lists of labels. By default, a page with <strong>any</strong> of the non-prefixed labels (that is, labels without a plus (+) or minus (-) sign immediately preceding it) will be listed. By using <code>operator=AND</code>, only pages with <strong>all</strong> of the supplied non-prefixed labels will be listed.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Be aware that this parameter only modifies the behaviour of the 'Label(s)' parameter and only affects label values without a plus (+) or minus (-) sign prefix. To avoid confusion or unexpected results, it is not recommended that the operator parameter be used in conjunction with any label values prefixed with '+' or '-' signs.</strong></td>
</tr>
<tr>
<td><strong>Show Labels for Each Page (showLabels)</strong></td>
<td>true</td>
<td>Show or hide labels for results.</td>
</tr>
<tr>
<td><strong>Show Space Name for Each Page (showSpace)</strong></td>
<td>true</td>
<td>Show or hide spaces for results.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------</td>
<td>---------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Reverse Sort (reverse)</td>
<td>false</td>
<td>Use this parameter in conjunction with the sort parameter described below. Set reverse=true to change the sort from ascending to descending. This parameter is ignored if the sort parameter is not specified.</td>
</tr>
</tbody>
</table>
| Sort By (sort)               | modified| Specify how the results should be sorted. To change the sort order from ascending to descending, use the reverse parameter described above. Note: If this parameter is not specified, the sort order defaults to descending order based on the last modification date. Values:  
  - creation — Sort by the date on which the content was added.  
  - title — Sort alphabetically by title.  
  - modified — Sort by the date on which the content was last updated. |
| Restrict to these Spaces (space) or (spaces) | @all, i.e. all spaces in your Confluence site. | This parameter allows you to filter content by space. The macro will display only the pages etc. which belong to the space(s) you specify here. You can specify one or more space keys, separated by a comma or a space.  
  - To exclude content in a specific space, put a minus sign (-) immediately in front of that space key. For example: If you specify a space key of -BADSPACE you will get only content which is not in the BADSPACE.  
  - To indicate that the results must come from a specific space, put a plus sign (+) immediately in front of that space key. For example: If you specify a space key of +GOODSPACE you will get only content in GOODSPACE. (Note that this is not particularly useful, because each content item belongs to one space only. If you put a plus sign next to one space key and list other space keys too, the other space keys will be ignored.) Special values:  
    - @self — The current space.  
    - @personal — All personal spaces.  
    - @global — All global spaces.  
    - @favorite — The spaces you have marked as favourite.  
    - @favourite — The same as @favorite above.  
    - @all — All spaces in your Confluence site.  
    - * — The same as @all above.  
  | List Title (title)           | None    | Adds a title or heading to the list.                                                                                                                                                                     |
| Include these Content Types Only (type) | all     | This parameter allows you to filter content by content type. The macro will display only the content of the type you specify here. You can specify one or more types, separated by a comma or a space.  
  - To exclude content of a given content type, put a minus sign (-) immediately in front of that content type. For example: If you specify a content type of -blogpost you will get pages and all other content except for blog posts.  
  | Display Excerpts (excerpts)  | false   | Displays the first line of excerpts for each page.                                                                                                                                                      |

**Examples**

1. Show content from a specific space

```plaintext
{contentbylabel:label-dogs,cats|space=PETS}
```
2. Show only results in current space

```
{contentbylabel:label=dogs,cats|space=3self}
```

3. Show results from all spaces

```
{contentbylabel:label=dogs,cats|space=3all}
```

4. Show only content of a specified type

The code below will show only pages (but not news items or other content types) with the labels 'dogs' or 'cats':

```
{contentbylabel:label=dogs,cats|type=page}
```

5. Do not show the labels in the results

```
{contentbylabel:label=dogs,cats|showLabels=false}
```

6. Do not show the space names in the results

```
{contentbylabel:label=dogs,cats|showSpace=false}
```

7. Display excerpts in the results

```
{contentbylabel:label=dogs,cats|excerpt=true}
```

8. Specify the maximum number of results to display

```
{contentbylabel:label=dogs,cats|max=99}
```

9. Sort by modification date

```
{contentbylabel:label=dogs,cats|sort=modified}
```

10. Change the sort order

```
{contentbylabel:label=dogs,cats|sort=modified|reverse=true}
```

**Labels List Macro**

The **Labels List macro** displays a hyperlinked alphabetical index of all labels within the current space.

The label index generated consists of numerous cells, each beginning with one or more letters of the alphabet or a number. Each label within the space is grouped alphanumerically into its appropriately headed cell.

Each label in the Labels List macro links directly to its Labels page, that lists the pages on which the label occurs within the current space.

**Screenshot: Labels List Macro segment**
On this page:

- Usage with the Macro Browser
- Usage in Wiki Markup
- Parameters

**Usage with the Macro Browser**

To insert the Labels List macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon  on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'insert' to put the macro into the page.

Once you've found the Labels List macro, click 'insert' to add it to your page.

**Usage in Wiki Markup**

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>Segment of what you will get</th>
</tr>
</thead>

### Navmap Macro

The **Navmap macro** displays the list of pages associated with a specified label as a navigation map.

A label must be specified for this macro.

### On this page:

- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
- Parameters
- Examples

### Usage with the Macro Browser

To insert the navmap macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'insert' to put the macro into the page.

Once you've found the navmap macro, click 'insert' to add it to your page.
### Usage with the Wiki Markup Editor

<td>View File Macro</td>
<td>View File Macro</td>
<td>View File Macro</td>
</tr>
</tbody>
</table>
Parameters

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in **Bold** text, while their equivalents in wiki markup are indicated in *(bracketed)* text. If the latter is not shown, then in wiki markup, the parameter’s name should be omitted and only its value should be added immediately after the colon symbol (*:`*).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required?</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Label</td>
<td>yes</td>
<td>none</td>
<td>Specify the label associated with the pages you want to show in the navigation map.</td>
</tr>
<tr>
<td>Map Title <em>(title)</em></td>
<td>no</td>
<td>none</td>
<td>Specify a title for the navigation map.</td>
</tr>
<tr>
<td>Number of Cells Per Row <em>(wrapAfter)</em></td>
<td>no</td>
<td>5</td>
<td>Specify the number of cells in a row</td>
</tr>
<tr>
<td>Cell Width <em>(Pixels)</em> <em>(cellWidth)</em></td>
<td>no</td>
<td>90 px</td>
<td>Specify the cell width</td>
</tr>
<tr>
<td>Cell Height <em>(Pixels)</em> <em>(cellHeight)</em></td>
<td>no</td>
<td>60 px</td>
<td>Specify the cell height</td>
</tr>
<tr>
<td>Navigation Map Theme <em>(theme)</em></td>
<td>no</td>
<td>Confluence</td>
<td>Define a theme for the navmap.</td>
</tr>
</tbody>
</table>

If you want to create your own navmap 'look and feel' (for example, one with rounded corners), you need to add a customised navmap macro theme file to the `WEB-INF/classes/templates/macros` directory. The file name convention to use is `navmap-mytheme.vm`. Use the name of your choice for the `mytheme` part of the file name, which is also the value you use for this parameter. Hence, if your theme was called `navmap-roundededges.vm`, use the value of `roundededges` for this parameter.

Examples

1. Specify a title for the navigation map

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>{navmap:html</td>
<td>title=Regarding HTML}</td>
</tr>
<tr>
<td>---------------</td>
<td>----------------------</td>
</tr>
<tr>
<td>Advanced HTML encoding</td>
<td>Anti-XSS documentation</td>
</tr>
<tr>
<td>clover-html--report</td>
<td>clover-repot</td>
</tr>
<tr>
<td>clover-repot</td>
<td>clover-repot</td>
</tr>
<tr>
<td>Edit in Word Link Macro</td>
<td>Edit in Word Link Macro</td>
</tr>
<tr>
<td>HTML Include Macro</td>
<td>HTML Include Macro</td>
</tr>
<tr>
<td>HTML Macro</td>
<td>HTML Macro</td>
</tr>
<tr>
<td>NewsFeedMake- r</td>
<td>Using Exported HTML in Word</td>
</tr>
</tbody>
</table>
2. Specify the number of cells in a row

The default is 5 cells.

3. Specify the cell width

The default width is 90px

4. Specify the cell height

The default is 60px

Popular Labels Macro

The **popular labels** macro renders a list/heatmap of the most popular labels used throughout your Confluence site or within a space. For example:

```
{popular-labels:style=heatmap|count=15}
```

On this page:

- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
- Parameters
- Examples

**Usage with the Macro Browser**

To insert the popular labels macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'Insert' to put the macro into the page.

Once you've found the popular labels macro, click 'Insert' to add it to your page.

**Usage with the Wiki Markup Editor**

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>{popular-labels:style=heatmap</td>
<td>count=15}</td>
</tr>
</tbody>
</table>
Parameters

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

Tip: Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in **Bold** text, while their equivalents in wiki markup are indicated in *(bracketed)* text. If the latter is not shown, then in wiki markup, the parameter's name should be omitted and only its value should be added immediately after the colon symbol (:).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required?</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of Labels to Display <em>(count)</em></td>
<td>no</td>
<td>100</td>
<td>Specifies the total number of labels to display in the heatmap.</td>
</tr>
<tr>
<td>Restrict Labels to this Space Key <em>(spaceKey)</em></td>
<td>no</td>
<td>none</td>
<td>Restricts the list of popular labels to the specified space.</td>
</tr>
<tr>
<td>Style of Labels <em>(style)</em></td>
<td>no</td>
<td>list</td>
<td>Displays the list of popular labels in standard bullet-point 'list' form or as a 'heatmap'. The heatmap style uses different font sizes depending on their rank of popularity, ordered by label names. The list style orders labels by popularity (highest first).</td>
</tr>
</tbody>
</table>

Examples

Show the 5 most popular labels in all spaces as a list

```
{popular-labels:count=5}
```

- confluence
- bamboo
- build
- crowd
- administration

Show the 20 most popular labels in the DOC space as a heatmap

```
{popular-labels:spaceKey=DOC:count=20}
```
recently used labels macro

The **recently used labels** macro renders a list of the most recently used labels in a specified scope (Global/Space/Personal).

### On this page:
- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
- Parameters

### Usage with the Macro Browser

To insert the recently used labels macro into a page using the Macro Browser,

1. Open your desired Confluence page, click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'Insert' to put the macro into the page.

Once you’ve found the recently used labels macro, click 'Insert' to add it to your page.

### Usage with the Wiki Markup Editor

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>(recently-used-labels)</td>
<td>favourite, database, mysql, events, usergroup, germany, hamburg, aughh, plan, bulk</td>
</tr>
</tbody>
</table>

### Parameters

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in **Bold** text, while their equivalents in wiki markup are indicated in *(bracketed)* text. If the latter is not shown, then in wiki markup, the parameter’s name should be omitted and only its value should be added immediately after the colon symbol (:).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required?</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of Labels to Display</td>
<td>no</td>
<td>10</td>
<td>Specifies the total number of labels to display in the list.</td>
</tr>
</tbody>
</table>
Scope for Retrieving Labels (scope) | no | global | Specifies the scope of labels to be displayed in the list. Valid values include:
- global — covers all non-personal spaces in the Confluence installation.
- space — the current space.
- personal — your own personal space.

List Style (style) | no | list | Displays the list of recently used labels in a horizontal 'list' style or in a 'table' style. The table style includes additional information such as the page to which the label was added and the user who added it.

Title (title) | no | none | Adds a title to the top of the list in table style. Titles are only visible when the List Style (style) parameter has been set to table.

Navigating Pages by Label

These instructions explain how to navigate Confluence pages by label. To start, you should open the 'View Labels' page.

Browsing Labels on the View Labels Page

After clicking a label on a Confluence page, you're shown the 'Browse Space > Labels' page. Here, click 'See content from all spaces' to open the 'View Labels' page.

Adding a Label to the Results

If you click another label, a new page loads, showing pages that contain both of the labels. You can continue to add labels to the results in this way.

Subtracting a Label From the Results

Once two labels are in use, links to subtract one label from the search appear at the end of the labels list. These are easily identified because these links have a preceding minus sign, like so:

Typing URLs To Find Labelled Pages

Here is an alternative method for quickly searching for labelled pages:

To search labelled pages by typing a URL,

1. Open a new web browser window.
2. In the URL bar of your web browser, type a URL like the following to search for multiple labels in pages:

   http://CONFLUENCE_HOSTNAME/label/foo+bar

3. Press Enter.
4. The 'View Labels' page will load, showing search results on pages with the labels 'foo' and 'bar'.

Screenshot: The View Labels page
Removing a label from a page

Labels are user-defined tag words that can be assigned to pages and spaces. You can use labels to categorise, identify or bookmark content in Confluence.

You can see the existing labels, and the pages which contain the labels, by Viewing Global Labels.

To remove a label from a page,

1. Go to the page that contains the label. All labels are displayed at the bottom of the page below the page content.

2. Click 'Edit' beside the list of labels (highlighted in yellow). Each of the labels will display a ✗ mark beside it.

3. Click ✗ to remove the label, then click 'Done'

RELATED TOPICS

Removing a space label

Labels are user-defined tag words that can be assigned to pages and spaces. You can use labels to categorise, identify or bookmark content in Confluence.

This page tells you how to remove a space label. If you want to remove a label from a page, read the instructions here.

To remove a space label,
1. Go to the ‘Advanced’ view for the space. To do this:
   - Go to a page in the space, open the ‘Browse’ menu and select ‘Advanced’. The ‘Advanced’ view will open.
2. Click ‘Edit’ beside the list of Space Labels. This will take you to a new screen, showing space labels in the left panel and team labels in the right panel. There will be a ‘Remove’ link beside each label.
3. Click ‘Remove’ to remove the label.

**Screenshot : Removing a space label**

**Labels**

You can group this space with other content you’ve labelled in Confluence using the box below.

- restricta-data (remove)
- categorising (remove)
- anotherlabel (remove)

**Add Label:**

Add

**Suggested Labels:**

favourite, known-issues-appserver, soap, url, customising, locknfee, tutorial, db, debug, seraph, user, documentation, i18n, sql, confluencehome, postgresql, plugin, export, other-settings, database, confluence-label-filter

Viewing Global Labels

Any page that has labels will have them listed together in a block, with the heading ‘Labels’.

Global labels are visible to all users with ‘view’ permission and personal labels are only visible to the user that created them.

To view global labels,

1. If you are in a page that has labels, clicking on a label will take you to the 'Label' tab of the 'Browse Space' view where all pages in the space with that label will be listed.

   Click on the link ‘See content from all spaces’ to view all pages with the same label across the site.

2. Go to the ‘Browse Space’ view. There are two ways to browse a space:
   
   • Go to a page in the space and select the option you want from the ‘Browse’ menu. The corresponding tab of the ‘Browse Space’ view will open.
   
   • Or click the icon next to the space name on the Dashboard. The ‘Pages’ tab of the ‘Browse Space’ view will open.

3. Click on the ‘Labels’ tab. You have the option to view labels in one of two ways:

   • Click ‘All labels’ to view all labels in the space. From this view, you can click on a link to view an alphabetical listing of all labels across the site. Clicking on a label will list all content in the space with that label. It will also display any related labels if they exist. Related labels are labels that frequently appear on pages together. For Example, if pages labelled with ‘sales’ also tend to have the label ‘marketing’, these will be displayed as related labels.

   • Click popular labels to view a list of the most frequently used labels in that space. From here, you can also view the most popular global labels across the site.

   Confluence defaults to one of these views when you go to the ‘Labels’ tab based on your preference on your last visit to the site.

   Each of these views also displays a list of up to fifteen most ‘Recent Labels’ and ‘Popular Labels’ in the space.

**Viewing labelled pages**

The easiest way to find labelled content is to do a quick search for it. If there is a label matching your query, it will be listed above the search results. Clicking on the link will display all content in the site with that label. (Clicking additional labels on the following page will conduct another search, adding that label to your existing search. See also Navigating Pages by Label.)

- You can view all labelled content for a space by going to the 'Label' tab in the 'Browse Space' view of a space.
- You can view content labelled with personal labels by going to your 'Profile' and clicking on the 'Label' tab.

**Viewing labelled content**

Searched for database in all spaces excluding Mail.
There are 201 matches in Mail. Include these matches.
Matching labels: database
Related labels: oracle, appserver

Results 1 - 10 of 225 for database.

* Migrate to another database (Confluence)
  ... document will outline the steps to move your existing Confluence data from one database to another. This is relevant to all users who previously used the embedded database for their evaluation (or longer) and would like to move to a more robust external database (such as Oracle, Postgres ...  
  Jul 20, 2005

**Advanced label searching**

Using the Search Box to find labelled pages

In the search box, you can use the labelText: prefix to search specifically for page labels.
Searching for ...

<table>
<thead>
<tr>
<th>confluence labelText:plugin</th>
<th>contains the word confluence or has the label plugin</th>
</tr>
</thead>
<tbody>
<tr>
<td>confluence AND labelText:plugin</td>
<td>contains the word confluence and has the label plugin</td>
</tr>
<tr>
<td>labelText:import labelText:plugin</td>
<td>has the label import or has the label plugin</td>
</tr>
<tr>
<td>labelText:import AND labelText:plugin</td>
<td>has the label import and has the label plugin</td>
</tr>
</tbody>
</table>

### Typing URLs to find labelled pages

In the URL bar of your web browser, you can type URLs like the following to search for multiple labels in pages:

```
http://CONFLUENCE_HOSTNAME/label/foo+bar
```

On pressing enter, the 'View Labels' page will load, showing search results on pages with the labels foo and bar.

### Viewing personal labels

Any page that has labels (global or personal) will have them listed at the bottom of the page. Personal labels are only visible to the user that created them.

**To view your personal labels,**

1. Go to your name at the top of the page. (This is the 'User' menu. A dropdown list will appear when your cursor hovers over the 'User' menu.)
2. Select 'Labels' from the dropdown list. The 'Labels' view will open.
3. This will display all content with personal labels. You will also see a list of your personal labels along with the number of pages that contain the label. Click a link to see all content with that label.

- Viewing Popular Labels

Take me back to the Confluence User Guide.

### Viewing Popular Labels

Popular labels are labels that are frequently used. Confluence allows you to view the most popular labels both within a space and across the site.

To view popular labels,

1. Go to the 'Browse Space' view. There are two ways to browse a space:
   - Go to a page in the space and select the option you want from the 'Browse' menu. The corresponding tab of the 'Browse Space' view will open.
   - Or click the ☰️ icon next to the space name on the Dashboard. The 'Pages' tab of the 'Browse Space' view will open.

2. Click the 'Label' tab.

3. Click on the link 'popular labels'. This will list the most popular labels in the space and also display a link to view all 'global popular labels' (across the site).
   - Clicking on a label will display all content in the site with that label.
   - Click 'global popular labels' to view the most popular labels in the site.

In both these views, you have the option to sort the listing of labels to display them 'alphabetically' or in order of their 'popularity'.

The bigger the font size, the more popular the label.

**Screenshot: Viewing popular labels**

<table>
<thead>
<tr>
<th>View: Popular Labels</th>
<th>All Labels</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>Below are the 6 most popular labels used in Documentation Staging 2. The bigger the text, the more popular the label. Click on a label to see its associated content.</td>
<td></td>
</tr>
<tr>
<td>See also: global popular labels</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Orders: alphabetically</th>
<th>by popularity</th>
</tr>
</thead>
<tbody>

### Working with News Overview
Each space in Confluence can publish its own news. News items may be announcements, journal entries, status reports or any other timely information you would categorise as 'news' pertaining to a space. News items are also known as 'blog posts'.

News items for a space are contained in the 'News' tab under the Browse Space view of a space. Confluence catalogues the news items chronologically and allows you to browse news for the space by navigating a calendar.

Creating and editing a news item is just as easy as creating and editing any other page in Confluence.

**What would you like to do?**

- View news
- Add news
- Edit news
- Link to news
- Delete news

**RELATED TOPICS**

- Subscribing to RSS Feeds within Confluence
- Tracking Updates Overview
- Blog Posts Macro

Take me back to Confluence User Guide

### Adding News

To add a news item for a space, you require 'Create News' permission which is assigned by a space administrator from the Space Administration screens. See Space permissions or contact a space administrator for more information.

To add a news item,

1. Click the 'Add News' link located at the top of every page in the space. This will bring up the 'Add News' screen.
2. Enter a title for your news item in the 'Title' text field at the top.
3. Enter your content in the text-entry box using Confluence markup or Rich Text as you would for any other page in Confluence.
4. Add labels if you want to categorise information this way.
5. If you want to backdate your news item, click 'edit' next to 'Posting Day', as shown in the screenshot below. You can set the date to earlier than today, but you cannot set it to a future date. And you can only change the date when creating the news item, not when editing a news item.
6. Preview and click 'Save'.

You can view your news item by going to the 'News' tab under the 'Browse Space' view of the space.

*Screenshot: Adding a news item*
Deleting News

To delete news, you require ‘Remove News’ permission which is assigned by a space administrator from the Space Administration screens. See Space Permissions or contact a space administrator for more information.

To delete a page,

1. Go to the news item and click on the ‘Edit’ tab.
2. Click on the ‘Remove’ link located at the top of the page. This is only displayed if you have permission to remove this news item.

Handy Hint

Deleted news items are stored in the trash and can be recovered by a space administrator.
Linking to News

Take me back to [Confluence User Guide](#)

Editing News

To edit a news item, you require 'Create News' permission which is assigned by a space administrator from the Space Administration screens. See Space Permissions or contact a space administrator for more information.

To edit a news item,

1. Click the 'Browse Space' link for the space. This is located at the top of every page and beside the space link on the dashboard.
2. Go to the 'News' tab. A list of the most recent news items within the space is presented. A calendar allows you to browse other news items. Locate the news item you wish to edit and click its title. This will open up the news item.
3. Click the 'Edit' tab. This will bring up the 'Edit' screen. Use regular Confluence Markup to edit the news item.
4. 'Preview' your changes if desired, and click 'Update'.

Editing a news item is similar to editing any other page in Confluence. However, there are a few things to keep in mind:

- You cannot change the date of an existing news item, but you can backdate when adding a news item.
- You cannot move a news item to another space.
- A news item has no parent.

**RELATED TOPICS**

Editing an Existing Page
Working with News Overview
Adding News
Deleting News
Blog Posts Macro

Take me back to Confluence User Guide

Linking to News

This page tells you how to link to a news item. You can also read about including blog posts on your page.

You need to edit in 'Wiki Markup' mode to create a link to a news item.

To link to a news item,

1. You need to know the title of the news item as well as the date on which it was created.
2. Convert the date into the format: year/month/day.
3. You can now create a link to the news item, like this:

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you get</th>
</tr>
</thead>
<tbody>
<tr>
<td>![2007/06/25/Sample News]</td>
<td>Sample News</td>
</tr>
</tbody>
</table>

Where:

'2007/06/25' is the date the news item was published.
'Sample News' is the title of the news item.

**Examples of Use**

You have three options:

1. **Directly providing the URL (absolute path)**

   ![http://confluence.atlassian.com/display/DOC/2007/06/25/Sample+News]

   http://confluence.atlassian.com/display/DOC/2007/06/25/Sample+News
2. Including the alias as well

my blog

3. Using the relative path (on the same server)

Note: You must provide the entire path to the news item.

[my blog]DOC:2007/06/25/Sample News

my blog

You can also link to a whole day's news items, just by leaving out the news item's title at the end of the link.

[my blog]DOC:2007/06/25

my blog

You must create the news item first

Linking to a news item that has not been created yet will not result in a link. News items are very tightly bound to the time at which they were created, so it makes no sense to link to them before they exist.

To link to a list of news items within a given space,

You need to know the key of the space.

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
</table>

Where:
'myConfluenceURL' is the URL address of your Confluence system, e.g. 'confluence.mycompany.com'.
'ABC' is the key of the relevant space.

Try the Blog Posts macro for an in-page display of news items

If you'd rather show a dynamic list of news items on your page, instead of a link to the news items, try the Blog Posts macro.

### Working with the Office Connector

The Office Connector is bundled with Confluence 2.10 and later. It allows you to:

- Use Microsoft Office or OpenOffice to edit a Confluence page.
- Import an Office document into Confluence, converting its content to wiki format.
- Attach an Office document to a Confluence page and display its content in Confluence, without converting the content.
- Edit the attached document in the Office application, directly from the Confluence page.

Please be aware that source code is currently not available for the Confluence Office Connector.

**Table of Contents**

- Office Connector Prerequisites
- Installing the Firefox Add-On for the Office Connector
- Editing a Confluence Page in an Office Application
- Importing an Office Document into Confluence
- Displaying an Office Document in Confluence
- Editing an Office Document from Confluence
- Editing an Office Presentation from Confluence
- Editing an Office Spreadsheet from Confluence

Configuring the Office Connector in the Confluence Administration Guide

Take me back to Confluence User Guide

### Office Connector Prerequisites

The page describes the software and setup you need to use the Office Connector.
Your System Administrator can enable or disable the Office Connector or parts of it. The Office Connector options can appear in different places on your Confluence page, depending on the themes and configuration of your Confluence site. Please refer to Configuring the Office Connector in the Confluence Administration Guide and discuss any configuration problems with your administrator.

On this page:

- Overall Prerequisites
- Prerequisites for Displaying and Viewing Documents in Confluence
- Prerequisites for Importing Documents into Confluence
- Prerequisites for Editing Confluence Pages and Documents in Office

Overall Prerequisites

- Ensure that Java 5 (JDK 1.5) or higher is installed on your Confluence server.
- The WebDAV plugin must be enabled, because the Office Connector uses WebDAV to transfer information to and from Office documents. Note that the WebDAV plugin is bundled with Confluence, and can be enabled or disabled by the System Administrator. If necessary, refer to the instructions on enabling plugins and configuring the WebDAV options.
- Ensure that your Confluence server's base URL is set correctly. (Check it by going to the 'General Configuration' screen in the Confluence Administration Console, as described in Configuring the Server Base URL.) When a user edits a wiki page in Word and then uploads the page back to the Confluence server, the base URL determines where the document will be saved. If the base URL is incorrect, the documents may be saved to a different Confluence server.

Prerequisites for Displaying and Viewing Documents in Confluence

If you want to make use of the View File macro or to view Office documents attached to a wiki page, you need the setup described below.

**Browsers and Flash Player**

You can use any browser to view an Office document on a wiki page, provided that you have installed Adobe Flash Player version 9 or later. You do not need to have an Office desktop application installed on your computer, in order to view Office documents in Confluence.

**Document Types**

To be displayed in Confluence, the document needs to be valid Microsoft Office 97-2003 document, of the following types:

- .doc
- .xls
- .ppt
- .pdf

If you are using OpenOffice to create and edit the documents, you will need to save your document in Microsoft Office 97-2003 format before attaching it to a Confluence page.

Prerequisites for Importing Documents into Confluence

- Document import can import documents of the file type .doc. These must be valid binary Word 97-2003 documents.

Prerequisites for Editing Confluence Pages and Documents in Office

The Office Connector allows you to edit Office documents embedded in a wiki page or to edit a wiki page in Word. To make use of these editing capabilities, you will need the setup described below.

**Browsers**

- If you are using Firefox, you will need to install a Firefox add-on. Firefox will prompt you to do this, the first time the add-on is required. You will find instructions in Installing the Firefox Add-On for the Office Connector.

**Editors**

To edit documents, you will need to have Microsoft Office, OpenOffice or NeoOffice installed. (See the configuration matrix below.)

- If you are using Firefox, you can choose which of the above editors you want to use. The Firefox add-on allows you to configure this option for each document type. See Installing the Firefox Add-On for the Office Connector.
- If you are using Internet Explorer, you will need Microsoft Office. You cannot edit documents in OpenOffice when using IE.

**Configuration Matrix**

You need one of the following software combinations to edit Office documents from your wiki page:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Office Version</th>
<th>Browser</th>
</tr>
</thead>
</table>
1. Windows Vista, or Windows XP with Service Pack 2 or 3
2. OpenOffice 2.x, or Microsoft Office XP, 2003 or 2007 (all documents must be in Microsoft Office 97-2003 compatible format)
3. Internet Explorer 6 or 7, or Firefox 2.x or 3.0

- Mac OS X
  - NeoOffice

- Linux
  - OpenOffice 2.x
  The only known supported Office editor for Linux is OpenOffice. But in theory it should work with any WebDAV-aware application.

 Firefox 2.x or 3.0

**RELATED TOPICS**

**Configuring the Office Connector in the Confluence Administration Guide**

Take me back to Confluence User Guide

**Installing the Firefox Add-On for the Office Connector**

If you are using Firefox as your browser, you will need to install an add-on into Firefox in order to use some features of the Office Connector. You will be prompted to install the add-on the first time you try to use a function which requires it.

For an overview of all Office Connector features, please refer to Working with the Office Connector.

**On this page:**

- Installing the Firefox Add-On
- Configuring the Add-On
  - Configuring the Add-On in Windows
  - Configuring the Add-On in Mac OS X
  - Configuring the Add-On in Linux
- Security Risks

**Installing the Firefox Add-On**

You will be prompted to install the add-on the first time you try to use a function which requires it. The add-on is required for editing a wiki page in Office, or for editing an Office document which is displayed on a wiki page.

1. When you choose an option which requires the Firefox add-on, you will see a popup window like this one:

   ![Plugin Download Popup](image)

   A plugin is required to use this feature. Would you like to download it?

   - OK
   - Cancel

2. Click ‘OK’. Some browsers may now ask you to confirm the download with a message bar across the top of the page, beneath the browser's address bar.
   - You may see a message like the yellow bar shown here:
Click 'Allow'.

- Or you may see a similar message with an 'Edit Options' button like this:

  ![Edit Options message](image)

  If you see the above message, click 'Edit Options'. You will then see an 'Allowed Sites' window like this:

  ![Allowed Sites window](image)

  You can specify which web sites are allowed to install add-ons. Type the exact address of the site you want to allow and then click 'Allow'.

  ![Address of web site](image)

  This window lets you tell Firefox that your Confluence server is allowed to install add-ons into Firefox. The 'Address of web site' box should already contain the address of your Confluence server.

- Click the 'Allow' button to add your Confluence server to the list.
- Go back to your Confluence page and try to edit your Office document again, e.g. by clicking 'Edit in Word' again.

Now you will see the option to install the add-on.

3. A 'Software Installation' window will appear, asking you to confirm the installation. The window will look something like the one below, but the URL will be the address of your own Confluence server:
4. Click 'Install Now'. The installation will happen and a window will pop up asking you to restart Firefox:

5. Make sure you have saved all your Confluence pages and any other work in your browser, then restart Firefox.

6. If Firefox asks you to confirm the restart, confirm it.

7. Firefox will close all the browser windows and will then start up again. You will see a window confirming that a new add-on has been installed, like this:
Configuring the Add-On

After you have installed the add-on into Firefox, you will need to configure it. Basically, you will associate a desktop application (editor) with each relevant file type. This tells the Office Connector which application to launch when it encounters a link to an editable file. The configuration is slightly different for each operating system, as described below.

Configuring the Add-On in Windows

The add-on can will automatically configure itself on Windows via the system registry. The first time you edit a new file type, the add-on will look up the default editor for that file type and make that the permanent setting.

If you want to override the registry settings, or if for some reason the automatic configuration is not working, you can configure the Firefox add-on manually.

1. In Firefox, go to the ‘Tools’ menu and select ‘WebDAV Launcher Options’, as shown in this screenshot:

2. A ‘WebDAV Launcher Options’ window will appear, allowing you to associate a specific file type (file extension) with a desktop application (editor). The window looks like this one:
3. In the 'File Extension' box, enter the extension for a particular file type. For example, you may want to associate the 'doc' file extension with Microsoft Word. To do this, you would type 'doc' in the File Extension text box:

4. Enter the 'Application Path' — Use one of the following methods to specify the associated application for editing the given file type:
   - Click the 'Auto' button to load the associated application from the Windows registry.
   - Alternatively, you can click the 'Browse' button to find the application on your computer.
   - Or you can manually type in the path to the application's executable file.
4. Click the 'Add' button. The file extension association will be added to the list. In the picture below you can see that the 'doc' extension has been associated with 'C:\Program Files\Microsoft Office\OFFICE11\WINWORD.EXE'. This is the path to the Microsoft Word 2003 executable on a specific Windows machine.

5. **Configuring the Add-On in Mac OS X**

The only supported Office editor for Mac OS X is NeoOffice. (See Office Connector Prerequisites.)

The add-on will try to configure itself automatically by looking under /Applications/NeoOffice, which is the default installation location for NeoOffice.

If the automatic configuration does not work, you will need to associate your NeoOffice executable with each file type.

The configuration procedure is similar to Windows, as shown above. Note that there is no 'Auto' button in Mac OS X.

**Configuring the Add-On in Linux**

The only known supported Office editor for Linux is OpenOffice. (See Office Connector Prerequisites.)
There is no automatic configuration on Linux. You will need to associate each file type with your Office editor in Firefox. Note that there is no ‘Auto’ button in Linux.

The configuration procedure is similar to Windows, as shown above.

For both Ubuntu and OpenSUSE, the configuration will look something like this:

<table>
<thead>
<tr>
<th>File Extension</th>
<th>Application Path</th>
</tr>
</thead>
<tbody>
<tr>
<td>doc</td>
<td>/usr/bin/oowriter</td>
</tr>
<tr>
<td>ppt</td>
<td>/usr/bin/ooimpress</td>
</tr>
<tr>
<td>xls</td>
<td>/usr/bin/oocalc</td>
</tr>
</tbody>
</table>

Security Risks

Please be aware that there are security risks in installing this add-on to Firefox. Internet Explorer is exposed to the same risks, because it can directly open Office documents. By installing the add-in into Firefox, you are exposing Firefox to the same risks.

Summary of the risks:

- Office documents can contain macro viruses. Before opening an Office document, make sure that you trust the source of the document.
- There are known flaws in the Office file formats and Microsoft Office that an attacker can exploit to gain control of your machine. Microsoft has fixed the known exploits in the latest Service Packs for all Microsoft Office versions. But new exploitations may arise at any time. Again, be sure that you trust the source of a document before opening it.

The add-on tries to reduce the risk by supporting the following:

- **Same origin policy** — The add-on can only open documents from the same host that initiated the action.

- **Digital signature** — The add-on is digitally signed. When you install the add-on please verify that it is signed by Benryan Software Inc.

- **Prompt the user for confirmation** — You will always be warned before a file is opened. Please read these warnings carefully before opening a file. The warning tells you the complete URL of the file as well as the complete application path of the application opening the file.

**Related Topics**

- Working with the Office Connector
- Office Connector Prerequisites
- Installing the Firefox Add-On for the Office Connector
- Editing a Confluence Page in an Office Application
- Importing an Office Document into Confluence
The Office Connector in Confluence allows you to edit a wiki page in Microsoft Word or in another Office application. This allows you to open the Confluence page in the Office editor of your choice and use the Office editor’s rich editing functionality to update the wiki page. You can then save the page directly back to Confluence.

This is just one of the ways Confluence can interact with Office documents. For an overview of all Office Connector features, please refer to Working with the Office Connector.

On this page:
- Prerequisites
- Editing a Confluence Page in an Office Application
- Troubleshooting

Prerequisites

The Office Connector allows you to edit Office documents embedded in a wiki page or to edit a wiki page in Word. To make use of these editing capabilities, you will need the setup described below.

Browsers

- If you are using Firefox, you will need to install a Firefox add-on. Firefox will prompt you to do this, the first time the add-on is required. You will find instructions in Installing the Firefox Add-On for the Office Connector.

Editors

To edit documents, you will need to have Microsoft Office, OpenOffice or NeoOffice installed. (See the configuration matrix below.)

- If you are using Firefox, you can choose which of the above editors you want to use. The Firefox add-on allows you to configure this option for each document type. See Installing the Firefox Add-On for the Office Connector.
- If you are using Internet Explorer, you will need Microsoft Office. You cannot edit documents in OpenOffice when using IE.

Configuration Matrix

You need one of the following software combinations to edit Office documents from your wiki page:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Office Version</th>
<th>Browser</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows Vista, or</td>
<td>OpenOffice 2.x, or</td>

<td></td>
</tr>
<tr>
<td></td>
<td>WebDAV-aware application.</td>
<td></td>
</tr>
</tbody>
</table>

Editing a Confluence Page in an Office Application

To edit a Confluence page in your Office editor,
1. View the Confluence page that you want to edit.

2. Open the 'Tools' menu and select 'Edit in Word'.

   The 'Edit in Word' option can appear in different places on your Confluence page, depending on the themes and configuration of your Confluence site. By default, the 'Edit in Word' option appears in the 'Tools' menu, as described above. Other possible locations are described in Configuring the Office Connector in the Confluence Administration Guide.

   [Screenshot: 'Edit in Word' option in the 'Tools' menu]
3. A window will pop up, asking you to confirm that you want to open this document.

Screenshot: Confirmation window in Firefox

[Image of Warning message]

This poses a security risk. If you didn’t initiate this action or you don’t trust the source of the file, please click Cancel.

4. Click ‘OK’. Your Office application will open, containing the content of the Confluence page as rich text.

5. Make the necessary changes, then save the document. The content will be saved back into Confluence.

Tips: All you need to do is save the document, via the ‘Save’ button or Ctrl-S or whatever. You do not need to do a ‘Save As’ and navigate back to the WebDAV repository. Your Office application knows where the document came from and does the work of saving back to the WebDAV file system.

6. Reload the Confluence page to see that your changes have been applied.

Troubleshooting

Problems? Please refer to our guide to the Office Connector limitations and known issues.

Configuring the Office Connector in the Confluence Administration Guide

Take me back to Confluence User Guide
**Importing an Office Document into Confluence**

The Office Connector in Confluence allows you to import an Office document into Confluence, so that the document's content is copied onto one or more Confluence pages.

This is just one of the ways Confluence can interact with Office documents. For an overview of all Office Connector features, please refer to Working with the Office Connector.

Your System Administrator can enable or disable the Office Connector or parts of it. The Office Connector options can appear in different places on your Confluence page, depending on the themes and configuration of your Confluence site. Please refer to Configuring the Office Connector in the Confluence Administration Guide and discuss any configuration problems with your administrator.

**On this page:**
- Prerequisites for the Document Import Feature
- Importing an Office Document into Confluence
  - Importing an Office Document onto a Single Wiki Page
  - Splitting an Office Document into Multiple Wiki Pages
  - Creating a New Wiki Page on Import

**Prerequisites for the Document Import Feature**

- Document import can import documents of the file type `.doc`. These must be valid binary Word 97-2003 documents.

Above are the prerequisites for the Office Connector's Document Import feature. For a full list of Office Connector prerequisites and limitations, please refer to:

- Office Connector Prerequisites
- Office Connector Limitations and Known Issues

**Importing an Office Document into Confluence**

The simplest way to import an Office document is to import the entire content of the document into a single wiki page. By default, the content of the document will replace any existing content on the wiki page.

More advanced options allow you to import the content into a new page, to split a single document into more than one wiki page, and to resolve conflicts in the titles of your pages.

These options are described below.

**Importing an Office Document onto a Single Wiki Page**

The simplest way to import an Office document is to import the entire content of the document into a single wiki page.

This method will replace any existing content on the wiki page.

To import an Office document onto a single wiki page,

1. Create a page in Confluence (see Creating a New Page) or go to an existing page whose content you want replaced.
2. Open the 'Tools' menu and select 'Doc Import'. The Office Connector import screen will appear.
3. Click the 'Browse' button and find the Office document on your local drive or network.
4. Click the 'Open' or 'Upload' button provided by your browser. The path and file name of the document will now appear in the text box on the Office Connector import screen.
5. Click the 'Import' button on the Office Connector import screen.
6. When the upload has finished, the content of the Office document will have been transformed into Confluence page content. You can now view and edit this page in the normal way, using the Confluence Rich Text Editor or Wiki Markup. There is no connection between the original Office document and this wiki page.

**Screenshot: Empty page ready for import**
Splitting an Office Document into Multiple Wiki Pages

When importing an Office document, you can split a single document into more than one wiki page, based on the heading styles in the document.

By default, the page names will be the same as the heading text. This may result in a conflict, if a page already exists with the same title. You can instruct the importer how to handle such conflicts.

To import an Office document into multiple wiki pages,
1. Create a page in Confluence (see Creating a New Page) or go to an existing page whose content you want replaced.

2. Open the 'Tools' menu and select 'Doc Import'. The Office Connector import screen will appear.

3. Click the 'Browse' button and find the Office document on your local drive or network.

4. Click the 'Open' or 'Upload' button provided by your browser. The path and file name of the document will now appear in the text box on the Office Connector import screen.

5. Click the 'Advanced' button on the Office Connector import screen. The Advanced options screen appears.

6. Choose a 'Root Page Title'. This will be the name of the top-most page created.

7. Under 'Title Conflicts', select one of the following options:
   - 'Imported pages become new versions of existing pages with the same title' — If a page already exists in Confluence with a title equal to the new page, then the content of the Office document will overwrite the content on the existing page. Page history will be preserved.
   - 'Imported pages should be auto-renamed if their titles conflict with existing pages' — Confluence will assign new names to any new page which would otherwise have a duplicate name. The content of existing pages will remain unchanged.
   - 'Delete existing pages with the same title as imported pages' — Before creating the new page, Confluence will remove any existing page which has the same title. This will remove the page history as well as the content.

8. In the dropdown list next to the 'Split' option, select the required heading level. Confluence will create a new wiki page for each occurrence of this heading level in your Office document. For example, if you choose 'Level 1' and your Office document has 5 level-1 headings then Confluence will create 5 pages, with titles equal to the text of the headings.

9. Check the 'Document Outline', which shows the structure of your document based on its heading styles. Each bullet point in the 'Document Outline' represents a new page after import into Confluence.

10. Click the 'Import' button.

11. When the upload has finished, the content of the Office document will have been transformed into Confluence page(s). You can now view and edit the page(s) in the normal way, using the Confluence Rich Text Editor or Wiki Markup. There is no connection between the original Office document and the wiki page(s) derived from it.

**Screenshot: Splitting a single Office document into multiple wiki pages**

---

**Creating a New Wiki Page on Import**

When you import a document into an existing wiki page, the content of the document will replace any existing content on the wiki page. You can use the advanced import options to create a new page instead.

The new page will become a child of the space's home page.

**To import an Office document into a new wiki page,**
1. Go to any existing page in the Confluence space where you want to import content.
2. Open the 'Tools' menu and select 'Doc Import'. The Office Connector import screen will appear.
3. Click the 'Browse' button and find the Office document on your local drive or network.
4. Click the 'Open' or 'Upload' button provided by your browser. The path and file name of the document will now appear in the text box on the Office Connector import screen.
5. Click the 'Advanced' button on the Office Connector import screen. The Advanced options screen appears.
6. For 'Root Page Title', enter a title for your new page.
7. For the 'Where to Import' option, choose 'Import as new page in current space'.
8. Click the 'Import' button.
9. When the upload has finished, the content of the Office document will have been transformed into a new Confluence page, as a child of the space's home page. You can now view and edit the page in the normal way, using the Confluence Rich Text Editor or Wiki Markup. There is no connection between the original Office document and the wiki page derived from it.

Displaying an Office Document in Confluence

You can display and view an Office document that is attached to a Confluence page. If you have an Office application installed, you will also be able to edit the Office document in your Office application.

This is just one of the ways Confluence can interact with Office documents. For an overview of all Office Connector features, please refer to Working with the Office Connector.

Your System Administrator can enable or disable the Office Connector or parts of it. The Office Connector options can appear in different places on your Confluence page, depending on the themes and configuration of your Confluence site. Please refer to Configuring the Office Connector in the Confluence Administration Guide and discuss any configuration problems with your administrator.

On this page:
Prerequisites

If you want to make use of the View File macro or to view Office documents attached to a wiki page, you need the setup described below.

Browsers and Flash Player

You can use any browser to view an Office document on a wiki page, provided that you have installed Adobe Flash Player version 9 or later. You do not need to have an Office desktop application installed on your computer, in order to view Office documents in Confluence.

Document Types

To be displayed in Confluence, the document needs to be valid Microsoft Office 97-2003 document, of the following types:

- .doc
- .xls
- .ppt
- .pdf

If you are using OpenOffice to create and edit the documents, you will need to save your document in Microsoft Office 97-2003 format before attaching it to a Confluence page.

Attaching and Displaying an Office Document

To attach and display an Office document in Confluence,

1. Attach the Office document to a Confluence page:
   - View the Confluence page where you want to display your document.
   - Open the 'Tools' menu and select 'Attachments'.
   - Browse for your Office document and upload it to the Confluence page.
   - You will find detailed instructions in Attaching Files to a Page.

2. Now you have two options for displaying the attached document:
   - You can display the document embedded into the Confluence page, via the Office Word, Office Excel, Office PowerPoint or View PDF macros in the macro browser. Refer to the detailed instructions on the View File macro.
   - You can also display a list of attachments via the attachments macro. People viewing the page will be able to click the 'View' link to see the Office or PDF document in Confluence.

   Alternatively, you can use the Wiki Markup syntax `{attachments}`.

Viewing and Editing the Attached Office Document

If an Office document is attached to a Confluence page, you can view the attached Office document from within Confluence. View the Office document in one of the following ways:

- Search for the Office document by file name, then click the 'View' link next to the Office document on the Search results page. (See Searching Confluence.)
- View the list of attachments for a specific Confluence page, then click the 'View' link next to the Office document on the Attachments page. (See Viewing Attachment Details.)
- View a list of attachments displayed on a page via the Attachments macro, then click the 'View' link next to the Office document in the list of attachments. (See Displaying List of Attachments in a Page.)
- View a Confluence page which has the Office document embedded in the page via the View File macro. (See View File Macro.)

Any Confluence user who has an Office application installed will also be able to launch their Office editor from within Confluence:

- Editing an Office Document from Confluence.
- Editing an Office Presentation from Confluence.
- Editing an Office Spreadsheet from Confluence.

- Troubleshooting

Prerequisites for Editing an Attached Office Document

The Office Connector allows you to edit Office documents embedded in a wiki page or to edit a wiki page in Word. To make use of these editing capabilities, you will need the setup described below.

**Browsers**
- If you are using Firefox, you will need to install a Firefox add-on. Firefox will prompt you to do this, the first time the add-on is required. You will find instructions in Installing the Firefox Add-On for the Office Connector.

**Editors**
To edit documents, you will need to have Microsoft Office, OpenOffice or NeoOffice installed. (See the configuration matrix below.)
- If you are using Firefox, you can choose which of the above editors you want to use. The Firefox add-on allows you to configure this option for each document type. See Installing the Firefox Add-On for the Office Connector.
- If you are using Internet Explorer, you will need Microsoft Office. You cannot edit documents in OpenOffice when using IE.

**Configuration Matrix**
You need one of the following software combinations to edit Office documents from your wiki page:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Office Version</th>
<th>Browser</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows Vista, or Windows XP with Service Pack 2 or 3</td>
<td>OpenOffice 2.x, or Microsoft Office XP, 2003 or 2007 (all documents must be in Microsoft Office 97-2003 compatible format)</td>
<td>Internet Explorer 6 or 7, or Firefox 2.x or 3.0</td>
</tr>
<tr>
<td>Mac OS X</td>
<td>NeoOffice</td>
<td>Firefox 2.x or 3.0</td>
</tr>
<tr>
<td>Linux</td>
<td>OpenOffice 2.x</td>
<td>Firefox 2.x or 3.0</td>
</tr>
</tbody>
</table>

The only known supported Office editor for Linux is OpenOffice. But in theory it should work with any WebDAV-aware application.

**Step 1. View the Office Document in Confluence**
If an Office document is attached to a Confluence page, you can view the attached Office document from within Confluence. View the Office document in one of the following ways:

- Search for the Office document by file name, then click the 'View' link next to the Office document on the Search results page. (See Searching Confluence.)
- View the list of attachments for a specific Confluence page, then click the 'View' link next to the Office document on the Attachments page. (See Viewing Attachment Details.)
- View a list of attachments displayed on a page via the Attachments macro, then click the 'View' link next to the Office document in the list of attachments. (See Displaying List of Attachments in a Page.)
- View a Confluence page which has the Office document embedded in the page via the View File macro. (See View File Macro.)

**Step 2. Open the Document in your Office Application**

To edit the Office document in your Office application,

1. Move your mouse pointer to the top of the document embedded in the Confluence page, until the hidden title bar appears.

_Screenshot: The title bar showing 'document.doc' above an embedded Office document_
2. Click the title bar above the embedded document. A window will pop up, asking you to confirm that you want to open this document.

_Screenshot: Confirmation window in Firefox_

**Warning!**

The following location is going to be opened on your computer:

By the program:

C:\Program Files\Microsoft Office\OFFICE11\WINWORD.EXE

This poses a security risk. If you didn't initiate this action or you don't trust the source of the file, please click Cancel.

[OK] [Cancel]

_Screenshot: Confirmation window in Internet Explorer_

**File Download**

Some files can harm your computer. If the file information looks suspicious or you do not fully trust the source, do not open the file.

You are opening the following file:

File name: document.doc
From: qa-eac.atlassian.com

[OK] [Cancel]
3. Click 'OK'. Now you may be asked to log in to your Confluence server.

![Screenshot: Logging in to Confluence]

4. Enter your Confluence username and password, then click 'OK'.
5. The Office document will open in your Office application.
6. Make the necessary changes, then save the document. It will be saved back into Confluence.

Configuring the Office Connector in the Confluence Administration Guide

Take me back to Confluence User Guide

Working with Bookmarks

Bookmarks will only be available if your Confluence administrator has enabled the Social Bookmarking plugin.

The Social Bookmarking plugin allows you to share bookmarks with your team. You can create a bookmark and save it in a Confluence space. To send the bookmark to other Confluence users, simply label it for their personal spaces or for public spaces. You can also subscribe to a bookmarks RSS feed.

A bookmark is a page which points to a website or other URL. The website or URL can be within or external to Confluence. The bookmark can also contain comments from the person who created the bookmark, telling you why the website is interesting.
Ask a colleague to bookmark interesting things for you while you're away

Going away, and don't want to monitor all your RSS feeds or watch the pages while you're on holiday?

- Ask a friend or a colleague to bookmark the news items and other sites that they think you should know about.
- When you get back, scan your bookmarks at your leisure. No worries that the important items will drop off your RSS feeds or clog your mailbox!

The plugin documentation gives an overview of the bookmark functionality. In addition, here are some detailed instructions:

- Adding a bookmark
- Adding a bookmark icon to your browser
- Viewing bookmarks
- Subscribing to a bookmarks feed
- Editing a bookmark
- Commenting on a bookmark
- Removing a bookmark
- Displaying bookmarks on a Confluence page

The .bookmarks page

You may notice that your space has a page called '.bookmarks'. This page is a container for all the bookmarks in the space. Do not delete or move this page, or you will lose all your bookmarks.

**Adding a bookmark**

The Social Bookmarking plugin allows you to share bookmarks with your team. You can create a bookmark and save it in a Confluence space. To send the bookmark to other Confluence users, simply label it for their personal spaces or for public spaces. You can also subscribe to a bookmarks RSS feed.

A bookmark is a page which points to a website or other URL. The website or URL can be within or external to Confluence. The bookmark can also contain comments from the person who created the bookmark, telling you why the website is interesting.

Permission to create bookmarks

You can save a bookmark in any space where you can create a page.
You can label a bookmark for any space, using the space key as described below.

You can add a bookmark via:

1. A bookmark icon on your browser toolbar. This is the quickest way.
2. A space's 'Add Bookmark' action.
3. The 'Add Bookmark' link on the 'Space Bookmarks' screen.

Where will the bookmark be stored? You can:

- Choose the space where the bookmark will be saved, and also
- optionally, send the bookmark to a colleague by labelling it for their personal space or label the bookmark for a global space.

To add a bookmark via the bookmark icon,
1. If you haven't already done so, add the bookmark icon to your browser toolbar.
2. Go to the website you're interested in.
3. Click the bookmark icon on your browser toolbar.

   ![Bookmarklet.png](https://www.example.com/bookmarklet.png) (Internet Explorer)

   ![BookmarkletFF.png](https://www.example.com/bookmarkletFF.png) (Firefox)
4. If you're not already logged in to Confluence, the Confluence login screen will appear. Log in as usual.
5. The 'Add Bookmark' screen will appear. Complete the information and save the bookmark, as described below.

To add a bookmark via a space's 'Add Bookmark' link,

1. Go to any Confluence page.
2. Click the 'Add Bookmark' link at the top right of the screen:

   ![Browse Space](https://www.example.com/browse-space.png) ![Add Page](https://www.example.com/add-page.png) ![Add News](https://www.example.com/add-news.png) ![Add Bookmark](https://www.example.com/add-bookmark.png)
3. The 'Add Bookmark' screen will appear. Complete the information and save the bookmark, as described below.

To add a bookmark via the 'Add Bookmark' link on the 'Space Bookmarks' screen,

1. Go to 'Browse Space' and click the 'Bookmarks' tab.
2. The 'Space Bookmarks' screen will appear. Click 'Add Bookmark' on the right of the screen.

   ![Add Bookmark](https://www.example.com/add-bookmark.png)
3. The 'Add Bookmark' screen will appear. Complete the information and save the bookmark, as described below.

To save, label and send the bookmark,

1. Add the bookmark using one of the methods described above.
2. The 'Add Bookmark' screen will appear, as shown below. Complete the following information:
   - **Title** – Enter a name for the bookmark. If you used the bookmark icon, the title will be set automatically.
     This title will appear on the 'Space Bookmarks' screen when you are viewing the bookmarks, to identify the bookmark.
     The bookmark is actually a page within the space. The bookmark title must be a unique page title within the space.
   - **URL** – Enter the URL of the website or other location which you find interesting or want to share with a colleague.
     If you used the bookmark icon on your browser toolbar, the URL will automatically be set to the website you were visiting.
   - **Space** – Choose the Confluence space where you want to save the bookmark. It will default to your personal space.
     The bookmark will appear on the 'Bookmarks in <spacename>' tab of this space. See Viewing Bookmarks.
   - **Description** – Enter any comments or message about this bookmark e.g. why you are sending the bookmark, or what is interesting about the website.
   - **Labels** – You can use the labels in two ways:
     - To send the bookmark to a particular Confluence space. Use 'for_spacekey' to send the bookmark to a global space, e.g. for_sales. Use 'for_~username' to send the bookmark to a Confluence user's personal space, e.g. for_~joebloggs.
     - To categorise the bookmark in the way we usually use labels.
3. Click the 'Save' button.
4. The bookmark will be saved in Confluence. You can view the bookmark on the 'Space Bookmarks' screen for the space you chose from the dropdown list. If you added a 'for_spacekey' label, the bookmark will also appear on the 'Space Bookmarks' screen for that space.
5. If you used the bookmark icon on your browser toolbar, you will be returned to the website you have just bookmarked.

Screenshot: Adding a bookmark
### Adding a Bookmark Icon to your Browser

The Social Bookmarking plugin allows you to share bookmarks with your team. You can create a bookmark and save it in a Confluence space. To send the bookmark to other Confluence users, simply label it for their personal spaces or for public spaces. You can also subscribe to a bookmarks RSS feed.

A bookmark is a page which points to a website or other URL. The website or URL can be within or external to Confluence. The bookmark can also contain comments from the person who created the bookmark, telling you why the website is interesting.

You can **add a bookmark icon on your browser toolbar.** This will make adding a bookmark quick and easy:

- When you want to create a bookmark pointing to a website, you don't have to leave the website. Just click the icon on your toolbar.
- The website title and URL will be automatically copied from the website to your bookmark.
- When you've finished adding the bookmark, you will be automatically returned to the website.

The bookmark icon will look something like this:

**Internet Explorer:**

![Bookmark in Confluence](image)

**Firefox:**

![Bookmark in Confluence](image)

There are two ways to add the icon to the browser toolbar:

- Drag the 'Bookmark in Confluence' link from the 'Space Bookmarks' page onto the browser toolbar. This method works for most browsers, including Firefox. Read the full instructions.
- Manually add the 'Bookmark in Confluence' link to your browser's 'Favorites - Links' folder. This method works for Internet Explorer 7. Read the full instructions.

You can change the bookmark name from 'Bookmark in Confluence' to something else, if you want to. Just use your browser's own functions for editing/organising bookmarks and bookmark properties.

Adding a Bookmark to your Browser’s Favorites

When using bookmarks in Confluence, you will find it useful to put a bookmark icon on your browser toolbar. Read an overview of adding the icon to your toolbar.

This page tells you how to add the Confluence bookmark link to your ‘Links’ folder within your browser’s ‘Favorites’. This will ensure that the link and its icon appear on the ‘Links’ toolbar. We are using Internet Explorer 7 as an example browser.

To add the bookmarks link to your Links folder,

1. First make sure that your browser’s ‘Links’ toolbar is showing: In IE7, click ‘Tools’ in the browser menu bar, then select ‘Toolbars’ and put a check mark next to ‘Links’.
2. Go to ‘Browse Space’ for any Confluence space and click the ‘Bookmarks’ tab.
3. The ‘Space Bookmarks’ screen will appear. Right-click the ‘Bookmark in Confluence’ link on the right of the screen, and select ‘Add to Favorites’...
4. The ‘Add a Favorite’ window appears. Edit the ‘Name’ to something like ‘Bookmark in Confluence’.
5. Select ‘Links’ from the ‘Create in’ dropdown list.
6. Click the ‘Add’ button.
7. The bookmark icon appears in your browser’s ‘Links’ toolbar:

You can change the bookmark name from ‘Bookmark in Confluence’ to something else, if you want to. Just use your browser’s own functions for editing/organising bookmarks and bookmark properties.

Screenshot: Showing the Links toolbar in IE7

This is the Links toolbar (empty at the moment)

Make sure the Links toolbar is showing in your browser

Screenshot: Adding the link to Favorites Links in IE7
Drag a Bookmark Link to your Browser

When using bookmarks in Confluence, you will find it useful to put a bookmark icon on your browser toolbar. Read an overview of adding the icon to your toolbar.

This page tells you how to drag the bookmark link from Confluence to the browser toolbar, using Firefox as an example browser.

To drag the link onto your browser toolbar,

1. First make sure that your browser's 'Bookmarks Toolbar' is shown.
   In Firefox, click 'View' in the browser menu bar, then select 'Toolbars' and put a check mark next to 'Bookmarks Toolbar'.
2. Go to 'Browse Space' for any Confluence space and click the 'Bookmarks' tab.
3. The 'Space Bookmarks' screen will appear. Click the 'Bookmark in Confluence' link on the right of the screen, and drag it onto the browser's 'Bookmarks Toolbar'.
4. The bookmark icon looks something like this:

   ![Bookmark in Confluence](image)

You can change the bookmark name from 'Bookmark in Confluence' to something else, if you want to. Just use your browser's own functions for editing/organising bookmarks and bookmark properties.

Editing or Commenting on a Bookmark

Permissions

In order to edit a bookmark, you must have **'create page permissions** for the space in which the bookmark was saved. In order to comment on a bookmark, you must have **'create comments permissions** for the space in which the bookmark was saved.

You can edit or comment on a bookmark by going to either of the following spaces:

- The space in which the bookmark was saved.
- The space for which the bookmark was labelled (if the bookmark was labelled for a space).

To edit or comment on a bookmark,

1. Go to 'Browse Space' and click the 'Bookmarks' tab.
2. The 'Space Bookmarks' screen will appear. Click one of the following tabs:
   - 'Bookmarks in <space name>': to display all the bookmarks which have been saved in this space.
   - 'Links for <space name>': to display all the bookmarks which have been labelled for this space.
3. To edit a bookmark:
   - Click 'Edit' next to the bookmark title.
   - The 'Update Bookmark' screen appears. Edit the information then click the 'Save' button.
4. To comment on a bookmark, do one of the following:
   - Click 'Comments' under the bookmark on the 'Space Bookmarks' screen.
   - Or click 'View Bookmark Page' on the 'Space Bookmarks' screen, then click 'Add Comment' on the bookmark page.

Screenshot: Editing or commenting on a bookmark
Removing a Bookmark

Permission to remove a bookmark

In order to remove a bookmark, you must have 'remove page' permissions for the space in which the bookmark was saved.

You can remove a bookmark by going to either of the following spaces:

- The space in which the bookmark was saved.
- The space for which the bookmark was labelled (if the bookmark was labelled for a space).

When you remove a bookmark, it disappears from all spaces i.e. the space in which it was saved and any spaces for which it was labelled.

To remove a bookmark,

1. Go to 'Browse Space' and click the 'Bookmarks' tab.
2. The 'Space Bookmarks' screen will appear. Click one of the following tabs:
   - 'Bookmarks in <space name>' – to display all the bookmarks which have been saved in this space.
   - 'Links for <space name>' – to display all the bookmarks which have been labelled for this space.
3. Click 'Remove' next to the bookmark title.
4. A confirmation screen appears, showing you the number of incoming links to the bookmark page. Click 'nn incoming link(s)' to see more information about the links.
5. Click 'OK' on the confirmation screen to remove the bookmark.

Screenshot: Deleting a bookmark
Subscribing to a Bookmarks RSS Feed

The Social Bookmarking plugin allows you to share bookmarks with your team. You can create a bookmark and save it in a Confluence space. To send the bookmark to other Confluence users, simply label it for their personal spaces or for public spaces. You can also subscribe to a bookmarks RSS feed.

A bookmark is a page which points to a website or other URL. The website or URL can be within or external to Confluence. The bookmark can also contain comments from the person who created the bookmark, telling you why the website is interesting.

What is an RSS feed?
RSS is a format used by a number of organisations to share news. You can subscribe to an ‘RSS feed’ and then use an ‘RSS reader’ to view the information in the feed. A feed is a URL (web address) which supplies the news upon request. A reader is a program which displays the news for you. Your reader may be on a website, an addon to your browser, part of your email program, or a stand-alone program.

More information:
- Overview of RSS on Wikipedia.
- Working with RSS in Confluence

The bookmarks feed is in RSS2 format. There are two feeds in each space:

- A feed for the bookmarks saved in a particular space. This might be:
  - Your personal space, where you store all the bookmarks of interest to you, as well as the bookmarks you have sent to other people.
  - A global space, where you or other people store bookmarks relevant to that space.
- A feed for the bookmarks labelled for a particular space. This might be:
  - Your personal space, where you can see the bookmarks other people have sent to you.
  - A global space, where you or other people have sent bookmarks relevant to that space.

To subscribe to the bookmarks saved in a particular space,
1. Go to 'Browse' and select 'Bookmarks' from the dropdown list. The 'Space Bookmarks' screen will appear.
2. Click the 'Bookmarks in <space name>' link.
3. This will display all the bookmarks which have been saved in this space. Get your feed from the link labelled 'Bookmark RSS Feed'. There are a few ways to add the feed to your RSS reader:
   • Drag the link into your RSS reader.
   • Or right-click the link and copy the link location, then paste it into your RSS reader.
   • Or click the link to open the feed in your browser. Then copy the feed URL from the browser's address bar and paste it into your RSS reader.

To subscribe to the bookmarks labelled for a particular space,

1. Go to 'Browse' and select 'Bookmarks' from the dropdown list. The 'Space Bookmarks' screen will appear.
2. Click the 'Links for <space name>' link.
3. This will display all the bookmarks which have been labelled for this space. Get your feed from the link labelled 'Bookmark RSS Feed'. There are a few ways to add the feed to your RSS reader:
   • Drag the link into your RSS reader.
   • Or right-click the link and copy the link location, then paste it into your RSS reader.
   • Or click the link to open the feed in your browser. Then copy the feed URL from the browser's address bar and paste it into your RSS reader.

**Viewing Bookmarks**

The **Social Bookmarking** plugin allows you to share bookmarks with your team. You can create a bookmark and save it in a Confluence space. To send the bookmark to other Confluence users, simply label it for their personal spaces or for public spaces. You can also subscribe to a bookmarks RSS feed.

A **bookmark** is a page which points to a website or other URL. The website or URL can be within or external to Confluence. The bookmark can also contain comments from the person who created the bookmark, telling you why the website is interesting.

This page tells you how to **view a list of bookmarks** in a space. If you want to include a list of macros on your Confluence page, use the **Bookmarks Macro**.

When viewing bookmarks, you can:

- View the bookmarks saved in a particular space. This might be:
• Your personal space, where you store all the bookmarks of interest to you, as well as the bookmarks you have sent to other people.
• A global space, where you or other people store bookmarks relevant to that space.
• View the bookmarks labelled for a particular space. This might be:
  • Your personal space, where you can see the bookmarks other people have sent to you.
  • A global space, where you or other people have sent bookmarks relevant to that space.
• Go to the bookmarked website or URL.

To view the bookmarks saved in a particular space,

1. Go to ‘Browse Space’ and click the ‘Bookmarks’ tab.
2. The ‘Space Bookmarks’ screen will appear. Click the ‘Bookmarks in <space name>’ tab.
3. This will display all the bookmarks which have been saved in this space, ordered by date with the most recent shown first. Click ‘View Bookmark Page’ if you want to open the Confluence page for this bookmark.

To view the bookmarks labelled for a particular space,

1. Go to ‘Browse Space’ and click the ‘Bookmarks’ tab.
2. The ‘Space Bookmarks’ screen will appear. Click the ‘Links for <space name>’ tab.
3. This will display all the bookmarks which have been labelled for this space, ordered by date with the most recent shown first. Click ‘View Bookmark Page’ if you want to open the Confluence page for this bookmark.

To go to the bookmarked website or URL,

1. Click the bookmark title. This is the bold, underlined name shown above the bookmark description on the ‘Space Bookmarks’ screen.
2. The website or other URL will open in your browser.

Take me back to Confluence User Guide

Working with Macros

Macros perform programmatic functions within a page and can be used to generate complex content structures or dynamic content.
Macros allow you to add extra functionality or include dynamic content in a page. For example, the Attachments macro will list a page's attachments in the page itself, so that readers do not have to visit the Attachments tab.

### On this page:
- Including a Macro in your Page
  - Including Macros with the Macro Browser
  - Including Macros with the Confluence Editor
  - Macro Parameters
  - Case Sensitivity in Macro Parameters
- Macros Shipped with your Confluence Installation
- Information about Other Macros
- Writing your own Macros

#### Including a Macro in your Page

There are two ways to include a macro in your page. You can add macros using the visual Macro Browser, or by manually typing a macro command into the editor.

##### Including Macros with the Macro Browser

To insert a macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'Insert' to put the macro into the page.

Once you've found the macro you want, click 'Insert' to add it to your page.

##### Including Macros with the Confluence Editor

In the Confluence editor, a macro is simply a command wrapped inside curly braces {...}.

For instance, the Attachments Macro is written as:

```
{attachments}
```

#### Macro Parameters

Many macros allow you to include optional parameters to control the macro's output.

With the Attachments Macro, for instance, you have two optional parameters:

- To specify the file formats of the attachments displayed.
- To choose whether or not you want old versions of the attachments displayed.

These optional parameters are included within the curly braces, following a colon, like this:

```
{attachments:patterns=*.jpg}
```

When specifying more than one parameter within the same macro, use the pipe symbol (|) to separate one from the other, like this:

```
{attachments:old=true|patterns=*.jpg}
```

#### Case Sensitivity in Macro Parameters

Macro parameters are case sensitive. In most cases, the macro will expect its parameters to be in lower case. Make sure you follow the documentation for the specific macro and match the expected case, otherwise the parameter may be ignored.

For example, this code correctly has the parameter 'patterns' with a lower case 'p' as expected by the Attachments Macro:

```
{attachments:patterns=*.jpg}
```

This code will not work, because the parameter 'Patterns' has an upper case 'p', which the Attachments Macro will not recognise:
Invalid macro code:

```{attachments:Patterns=.*jpg}```

## Macros Shipped with your Confluence Installation

When you download your Confluence installation file, many macros are shipped with the download. Below is a list of the macros currently shipped with Confluence. Click a macro name for details of the usage, including optional parameters and examples.

<table>
<thead>
<tr>
<th>Macro Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attachments Macro</td>
<td>Displays a list of attachments belonging to the current page.</td>
</tr>
<tr>
<td>Blog Posts Macro</td>
<td>Lists the most recent news items in the space.</td>
</tr>
<tr>
<td>Bookmarks Macro</td>
<td>Includes a list of bookmarks on a Confluence page.</td>
</tr>
<tr>
<td>Change-History Macro</td>
<td>Displays a history of updates made to a page.</td>
</tr>
<tr>
<td>Chart Macro</td>
<td>Displays a chart based on tabular data.</td>
</tr>
<tr>
<td>Cheese Macro</td>
<td>Displays the words &quot;I like cheese!&quot;</td>
</tr>
<tr>
<td>Children Display Macro</td>
<td>Displays the children and descendants of the current page.</td>
</tr>
<tr>
<td>Code Block Macro</td>
<td>Displays code in your document with the appropriate syntax highlighting.</td>
</tr>
<tr>
<td>Color Text Macro</td>
<td>Changes the colour of a block of text.</td>
</tr>
<tr>
<td>Column Macro</td>
<td>Used with the Section Macro. Defines columns within the page.</td>
</tr>
<tr>
<td>Content by Label Macro</td>
<td>Renders a list of content associated with specific labels.</td>
</tr>
<tr>
<td>Create Space Button Macro</td>
<td>Renders a create space button linked to the create space page.</td>
</tr>
<tr>
<td>Tasklist Macro</td>
<td>Displays a dynamic task list which can be modified in 'view' mode.</td>
</tr>
<tr>
<td>Edit in Word Link Macro</td>
<td>Displays an 'Edit in Word' icon on your page.</td>
</tr>
<tr>
<td>Excerpt Macro</td>
<td>Allows you to define a part of the page as the page's 'excerpt' which is then used by other macros to summarise a page's content.</td>
</tr>
<tr>
<td>Excerpt Include Macro</td>
<td>Allows you to display an excerpt from another page within the current page.</td>
</tr>
<tr>
<td>Favourite Pages Macro</td>
<td>Displays a list of your favourite pages.</td>
</tr>
<tr>
<td>Excerpt Include Macro</td>
<td>Includes one page's excerpt in another.</td>
</tr>
<tr>
<td>Gallery Macro</td>
<td>Forms a thumbnail gallery of all images attached to a page.</td>
</tr>
<tr>
<td>Global Reports Macro</td>
<td>Renders a list of links to global reports within a table.</td>
</tr>
<tr>
<td>HTML Macro</td>
<td>Renders your specified HTML code within the current page.</td>
</tr>
<tr>
<td>HTML Include Macro</td>
<td>Includes the content of an external HTML file into a Confluence page.</td>
</tr>
<tr>
<td>IM Presence Macro</td>
<td>Displays graphically when a contact is online.</td>
</tr>
<tr>
<td>Include Page Macro</td>
<td>Inserts the contents of the specified page into the current one.</td>
</tr>
<tr>
<td>Info Macro</td>
<td>Displays a block of text in a blue highlight box.</td>
</tr>
<tr>
<td>JIRA Issues Macro</td>
<td>Displays a list of JIRA issues in a page.</td>
</tr>
<tr>
<td>JIRA Portlet Macro</td>
<td>Displays a JIRA dashboard portlet in Confluence.</td>
</tr>
<tr>
<td>JUnit Report Macro</td>
<td>Display a summary of JUnit test results.</td>
</tr>
<tr>
<td>Livesearch Macro</td>
<td>Add a dynamic search box to a wiki page.</td>
</tr>
<tr>
<td>Loremipsum Macro</td>
<td>Display a few paragraphs of pseudo-Latin text.</td>
</tr>
<tr>
<td>Navmap Macro</td>
<td>Renders the list of pages associated with a specified label as a navigable map.</td>
</tr>
<tr>
<td>Noformat Macro</td>
<td>Displays a block of text in monospace font.</td>
</tr>
<tr>
<td>Nolink and nl Macros</td>
<td>Prevents the browser from automatically hyperlinking a URL.</td>
</tr>
</tbody>
</table>
### Note Macro
Displays a block of text in a yellow highlight box.

### Panel Macro
Displays a block of text within a fully customisable panel.

### Pagetree Macro
Displays a dynamic, hierarchical list of pages starting from a specified parent (root) page.

### Pagetree Search Macro
Adds a search box to your Confluence page and searches a hierarchy of pages starting from a specified parent (root) page.

### Recently Updated Macro
Displays a list of recently changed content (pages, news items, comments, etc).

### Recently Used Labels Macro
Lists labels most recently used in a specified scope (Global, Space, or Personal).

### Related Labels Macro
Lists labels frequently appearing on the same pages as the current page's labels.

### RSS Feed Macro
Displays the contents of an RSS feed.

### Search Macro
Searches Confluence, and includes the results in the page.

### Section Macro
Used with the Column Macro to define columns within the page.

### Space Details Macro
Includes the summary of a Confluence space in the page.

### Spaces List Macro
Displays a list of all spaces visible to the user.

### Tip Macro
Displays a block of text in a green highlight box.

### Userlister Macro
Displays a list of Confluence users, from an optional group.

### View File Macro
Embeds an Office document into your Confluence page.

### Warning Macro
Displays a block of text in a red highlight box.

### Web-Widget Macro
Same as the Widget macro.

### Welcome Message macro
Includes the Confluence site welcome message.

### Widget Macro
Displays videos, slide shows, twitter chats, documents and more, sourced from other web sites and displayed on your Confluence page.

### Information about Other Macros
Other macros are available as plugins or as user macros, and can be installed by your Confluence administrator.

Customers using Adaptavist macros or plugins might be interested in the [Adaptavist's Confluence user guide](#).

Some examples are:

- `{toc}` macro, provided by the [Table of Contents Plugin](#) - full documentation by CustomWare.
- `{float}` macro and others, provided by the [Composition plugin](#) - full documentation by CustomWare.

### Writing your own Macros

To learn how to write your own macro, take a look at the following documentation:

- User macros are simple template-like macros that allow you to create simple formatting macros using the Confluence web interface. Read more about [User Macros](#).
- The [Confluence Plugin Guide](#) tells you how to develop a plugin for Confluence.

### RELATED TOPICS

- [Plugin Index](#)
- [User Macros](#)

Take me back to the [Confluence User Guide](#).

### Anchor Macro

⚠️ The Anchor Macro is documented in [Working with Anchors](#).
Attachments Macro

The attachments macro is documented on Displaying List of Attachments in a Page.

Blog Posts Macro

The Blog Posts Macro allows you to display news items (blog posts) on a wiki page. Clicking on a title takes you to the news item. The blog posts macro will generate output like the screenshot below:

Screenshot: The Blog Posts Macro in Confluence

On this page:

- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
- Parameters
- Examples
  - Specify the number of news items you want displayed
  - Display short excerpts from each news item in the list
  - Display only the titles of the news item
  - Choose how far back in time Confluence should look for the news items
  - Filter items using labels
  - Filter items using spaces
  - Combine parameters to filter the news items
  - Sort the results

Usage with the Macro Browser

To insert the blog posts macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. TheMacro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'Insert' to put the macro into the page.

Usage with the Wiki Markup Editor

Simply type the following into the Wiki Markup editor:

```
{blog-posts}
```

In the example below, we show the news items from a user's personal space on this Confluence site. (The person's username is ~mryall.)

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>{blog-posts}</td>
<td></td>
</tr>
</tbody>
</table>
Parameters

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

<i>Note</i>: Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in Bold text, while their equivalents in wiki markup are indicated in (bracketed) text. If the latter is not shown, then in wiki markup, the parameter's name should be omitted and only its value should be added immediately after the colon symbol (:).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(author)</td>
<td>None</td>
<td>Filter the results by author. The macro will display only the news items which are written by the author(s) you specify here. You can specify one or more authors, separated by a comma.</td>
</tr>
<tr>
<td>Content Type to Display</td>
<td>entire</td>
<td>Available values:</td>
</tr>
<tr>
<td>(content)</td>
<td></td>
<td>- content=excerpts — Display short excerpts from each news item. After each excerpt, the words 'Read more...' will offer a link allowing the user to click through to the full news item, if the content is over 500 characters long.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- content=titles — Display a list of news items, showing titles only.</td>
</tr>
<tr>
<td>Restrict to these Labels</td>
<td>None</td>
<td>Filter the results by label. The macro will display only the news items which are tagged with the label(s) you specify here. You can specify one or more label values, separated by a comma or a space.</td>
</tr>
<tr>
<td>(label)</td>
<td></td>
<td>- To exclude content which matches a given label, put a minus sign (-) immediately in front of that label value. For example: If you specify a label value of -badpage you will get only content which is not labelled with 'badpage'.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- To indicate that the results must match a given label value, put a plus sign (+) immediately in front of that label value. For example: If you specify a label value of +superpage,+goodpage you will get only content which has at least two labels, being 'superpage' and 'goodpage'.</td>
</tr>
<tr>
<td>Restrict to these Labels</td>
<td>None</td>
<td>Exactly the same as label above.</td>
</tr>
<tr>
<td>(labels)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Maximum Number of News</td>
<td>15</td>
<td>Specify the maximum number of results to be displayed. Note that the results are sorted first, and then the maximum parameter is applied.</td>
</tr>
<tr>
<td>Items (max)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Maximum Number of News</td>
<td>15</td>
<td>Exactly the same as max above.</td>
</tr>
<tr>
<td>Items (maxResults)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Reverse Sort (reverse)</td>
<td>false</td>
<td>Use this parameter in conjunction with the sort parameter described below. Set reverse=true to change the sort from ascending to descending order.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- this parameter is ignored if the sort parameter is not specified.</td>
</tr>
<tr>
<td><strong>Sort By</strong> (sort)</td>
<td><strong>Restrict to these spaces</strong> (space)</td>
<td><strong>Time Frame</strong> (time)</td>
</tr>
<tr>
<td>-------------------</td>
<td>--------------------------------------</td>
<td>---------------------</td>
</tr>
<tr>
<td><em>creation</em></td>
<td>@self, i.e. the space which contains the page on which the macro is coded</td>
<td>no limit</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Specify how the results should be sorted. To change the sort order from ascending to descending, use the `reverse` parameter described above.

1. If this parameter is not specified, the sort order defaults to descending order based on the creation (publish) date.

Values:
- `creation` — Sort by the date on which the content was added.
- `title` — Sort alphabetically by title.
- `modified` — Sort by the date on which the content was last updated.

This parameter allows you to filter content by space. The macro will display only the pages which belong to the space(s) you specify here.

You can specify one or more space keys, separated by a comma or a space.

- To exclude content in a specific space, put a minus sign (-) immediately in front of that space key. For example: If you specify a space key of `-BADSPACE` you will get only content which is not in the BADSPACE.
- To indicate that the results **must** come from a specific space, put a plus sign (+) immediately in front of that space key. For example: If you specify a space key of `+GOODSPACE` you will get only content in GOODSPACE. (Note that this is not particularly useful, because each content item belongs to one space only. If you put a plus sign next to one space key and list other space keys too, the other space keys will be ignored.)

Special values:
- `@self` — The current space.
- `@personal` — All personal spaces.
- `@global` — All global spaces.
- `@favorite` — The spaces you have marked as `favourite`.
- `@favourite` — The same as `@favorite` above.
- `@all` — All spaces in your Confluence site.
- `@` — The same as `@all` above.

2. When specifying a personal space, remember to use the tilde (~) sign in front of the username, such as `~jbloggs` or `~jbloggs@example.com`.

Exactly the same as `space` above.

Specify how far back in time Confluence should look for the news items to be displayed.

Available values:
- `m` — Minutes
- `h` — Hours
- `d` — Days
- `w` — Weeks

For example, `time=12h` would display those news items created in the last twelve hours, and `time=7d` would show news items created in the last seven days.

Examples

1. *Specify the number of news items you want displayed*

   The following code will display a maximum of five news items:

   ```
   {blog-posts:max=5}
   ```

2. *Display short excerpts from each news item in the list*

   ```
   {blog-posts:content=excerpts}
   ```

3. *Display only the titles of the news item*
4. Choose how far back in time Confluence should look for the news items

The following code will display all news items posted in the last twelve hours.

```
{blog-posts:time=12h}
```

The following code will display all news items posted in the last 2 weeks.

```
{blog-posts:time=2w}
```

5. Filter items using labels

The following code will display news items that contain the labels 'atlassian' or the label 'confluence' (or both):

```
{blog-posts:labels=atlassian,confluence}
```

The following code will display news items that contain the labels 'atlassian' and 'confluence' — each news item must be tagged with both labels:

```
{blog-posts:labels=+atlassian,+confluence}
```

6. Filter items using spaces

The following code will display items from the 'Marketing' space (space key is MKTG) and Joe Smith's personal space (space key is ~jsmith):

```
{blog-posts:spaces=MKTG,~jsmith}
```

7. Combine parameters to filter the news items

The following code will display the latest 10 items in the 'Marketing' space (space key is MKT) with the label 'logo'. The items will be displayed as a list of titles only:

```
{blog-posts:max=10|labels=logo|spaces=MKT|content=titles}
```

8. Sort the results

Use the code below to sort the list of items by date last modified, with the most recent at the top:

```
{blog-posts:sort=modified|reverse=true}
```

**Bookmarks Macro**

This page describes the **Bookmarks Macro**, provided by the Social Bookmarking plugin. Please refer to Working with Bookmarks for details of how to add, view and subscribe to bookmarks.

Use the bookmarks macro to include a list of bookmarks on a Confluence page. By default, the macro will display the bookmarks saved in the current space. The bookmarks macro renders information as shown in the screenshot below.

**Screenshot: Bookmarks Macro**
Usage with the Macro Browser

To insert the bookmarks macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'insert' to put the macro into the page.

Once you’ve found the bookmarks macro, click 'insert' to add it to your page.

Usage with the Wiki Markup Editor

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>{bookmarks}</code></td>
<td>Testing news</td>
</tr>
</tbody>
</table>

Parameters

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in **Bold** text, while their equivalents in wiki markup are indicated in (bracketed) text. If the latter is not shown, then in wiki markup, the parameter’s name should be omitted and only its value should be added immediately after the colon symbol (:).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum Number of Bookmarks</td>
<td>15</td>
<td>The maximum number of bookmarks to display.</td>
</tr>
<tr>
<td>(max)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Search these Spaces Only</td>
<td>Current</td>
<td>A list of spaces to search for, separated by commas. The macro will display the bookmarks saved in these spaces. Meta space names @all, @personal, @global can also be used.</td>
</tr>
<tr>
<td>(spaces)</td>
<td></td>

<td>true</td>
<td>Display the space the bookmark is saved in.</td>
</tr>
<tr>
<td>Show Link to Actual Bookmark</td>
<td>true</td>
<td>Display a link to the actual bookmark page.</td>
</tr>
</tbody>
</table>

### Examples

**Specify the number of bookmarks you want displayed:**

```
{bookmarks:max=5}
```

**Specify the space(s) where the bookmarks are saved:**

The following markup will show the bookmarks in the personal space of user 'jbloggs' and in the 'sales' space.

```
{bookmarks:spaces=~jbloggs,sales}
```

**Specify the space(s) where the bookmarks are saved and the person who created the bookmarks:**

The following markup will show the bookmarks created by user 'jbloggs' in his personal space and in the 'sales' space.

```
{bookmarks:spaces=~jbloggs,sales|creators=jbloggs}
```

**Display only the bookmark titles:**

We have forced the line-breaks in this example. Your code should consist of a single line.

```
{bookmarks:showAuthor=false|showDate=false |
|showDescription=false|showEditLinks=false |
|showLabels=false|showListHeader=false |
|showSpace=false|showViewLink=false}
```
**Change-History Macro**

The **Change-History Macro** shows the history of updates made to a page — version number, author, date and comment. It displays this information inline, as shown in the following screenshot.

**Screenshot: The Change-History Macro in Confluence**

<table>
<thead>
<tr>
<th>Version</th>
<th>Date</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Current Version (v. 3)</td>
<td>Apr 01, 2009 16:55</td>
<td>Conf Admin</td>
</tr>
<tr>
<td>v. 2</td>
<td>Apr 01, 2009 13:09</td>
<td>Conf Admin</td>
</tr>
<tr>
<td>v. 1</td>
<td>Apr 01, 2009 11:03</td>
<td>Conf Admin</td>
</tr>
</tbody>
</table>

<tr>
<td>v. 1</td>
<td>Apr 17, 2008 20:28</td>
</tr>
</tbody>
</table>

There are no parameters for this macro.

**Chart Macro**

The **Chart Macro** allows you to display a chart based on tabular data. When entering the macro code, you will supply the data and choose the format of the chart.

The chart macro appears as shown in the following screenshot.

**Screenshot: The Chart Macro in Confluence**
Usage with the Macro Browser

To insert the chart macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'Insert' to put the macro into the page.
4. Once you've found the chart macro, select a type of chart from the parameter settings (listed below).
5. You will also need to manually enter your chart data as a Wiki markup table into the 'body text' field, like so:

| produce| orange| lemon| grape| pear |
|week 1 |10| 20| 30| 40 |50|
|week 2 |100|200|300|400|500|

6. Click 'Preview' to check that your settings and data are correct.
7. Finally, click 'Insert' to add the chart to your page.

Usage with the Wiki Markup Editor.

Here is a simple example of a pie chart.
Here is a simple example of a bar chart.

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>![chart:type=bar</td>
<td>title=Fish Sold]</td>
</tr>
<tr>
<td>Fish Type</td>
<td></td>
</tr>
<tr>
<td>2004</td>
<td></td>
</tr>
<tr>
<td>2005</td>
<td></td>
</tr>
<tr>
<td>Herring</td>
<td>9,500 8,300</td>
</tr>
<tr>
<td>Salmon</td>
<td>2,900 4,200</td>
</tr>
<tr>
<td>Tuna</td>
<td>1,500 1,500</td>
</tr>
<tr>
<td>![chart]</td>
<td></td>
</tr>
</tbody>
</table>

**Parameters**

- **Chart Type Parameters**
- **Display Control Parameters**
- **Title and Label Customisation Parameters**
- **Data Specification Parameters**
- **Colour Customisation Parameters**
- **Axis Customisation Parameters**
- **Pie Chart Customisation Parameters**
- **Attachment Parameters**

**Chart Type Parameters**

These parameters determine what type of chart to display and the way the chart looks.
• **type** - The type of chart to display. Both standard charts and XY charts are supported. XY charts have numerical x and y axes. The x values may optionally be time based (see the `timeSeries` parameter). The following chart types are available:

**Standard charts**

- `pie` (default)
- `bar`
- `line`
- `area`

**XY plots**

- `xyArea`
- `xyBar`
- `xyLine`
- `xyStep`
- `xyStepArea`
- `scatter`
- `timeSeries`

**Other charts**

- `gantt` - beta

• **orientation** — A bar, line, or area chart will be displayed vertically (y axis is vertical) unless 'orientation=horizontal' is specified.
• **3D** — A pie, bar, or line chart will be shown in 3D if '3D=true' is specified.
• **stacked** — A bar or area chart will be shown with stacked values if 'stacked=true' is specified.
• **showShapes** — Shapes will be shown at each data point in a line chart unless showShapes=false.
• **opacity** — A percentage value between 0 (not visible) and 100 (non-transparent) that determines how opaque the foreground areas and bars are. Defaults are:
  • 75 percent for 3D charts
  • 50 percent for non-stacked area charts
  • 100 percent for all other charts

**Display Control Parameters**

- **width** — The width of the chart in pixels (default is '300').
- **height** — The height of the chart in pixels (default is '300').
- **dataDisplay** — Default is false to not display the rendered body of the macro (usually the data tables). When dataDisplay=true or dataDisplay=after, the data will be displayed after the chart. When dataDisplay=before, the data will be displayed before the chart.
- **imageFormat** — Default is png. Format of generated image. Valid formats are png and jpg. Other formats may be also be valid if installed on your server.

**Title and Label Customisation Parameters**

- **title** — The title of the chart.
- **subTitle** — A subtitle for the chart using a smaller font.
- **xLabel** — The label to use for the x (domain) axis.
- **yLabel** — The label to use for the y (range) axis.
- **legend** — A legend will be displayed unless 'legend=false' is specified.

**Data Specification Parameters**

The data for the chart is taken from tables found when the macro body is rendered. These options control how this data is interpreted. By default, numeric and date values are interpreted according to the Confluence global default language (locale) formats. If conversion fails, other languages defined to Confluence will be tried. Additional conversion options can be specified using the parameters below.

- **tables** — Comma separated list of table ids and/or table numbers (starting at 1) contained within the body of the macro that will be used as the data for the chart. Defaults to all first level tables. If data tables are embedded in other tables, then table selection will be required. This occurs when more complex formatting is done (for example using section and column macros). See [Macros know to cause problems](#).
- **columns** — Comma separated list of column labels and/or column titles and/or column numbers for tables used for chart data. This applies to all tables processed. Defaults to all columns. Columns are enumerated starting at 1. Column label is the text for the column in the header row. Column title is the (html) title attribute for the column in the header row.
- **dataOrientation** — The data tables will be interpreted as columns (horizontally) representing domain and x values unless 'dataOrientation=vertical'.
- **timeSeries** — If 'true', the x values in an XY plot will be treated as time series data and so will be converted according date formats.
- **dateFormat** — For time series data, the date format allows for additional customization of the conversion of data to date values. By default, the Confluence language defined date formats will be used. If a dateFormat is specified, it will be the first format used to interpret date values. Specify a format that matches the format of the time series data. See [simple date format](#).
- **timePeriod** — Specify the time period for time series data. Default is 'Day'. This defines the granularity of how the data is interpreted. Valid values are: Day, Hour, Millisecond, Minute, Month, Quarter, Second, Week, Year.
- **language** — If provided, the language and country specification will be used to create additional number and date formats to be used for data conversion. This specification will be used before the default languages automatically used. Valid values are 2 character **ISO 639-1** alpha-2 codes.
- **country** — Used in combination with the language parameter. Valid values are 2 character **ISO 3166 codes**.
- **forgive** — Default is true to try to convert numeric and date values that do not totally match any of the default or user specified
formats. Specify forgive=false to enforce strict data format. Data format errors will cause the chart to not be produced.

**Colour Customisation Parameters**

See the notation guide for details on how to specify colours.

- **bgColor** — Colour (default is 'white') to use as the background of the chart.
- **borderColor** — Colour of a border around the chart. Default is to not show a border.
- **colors** — Comma separated list of colours used to customise category, sections, and series colours.

**Axis Customisation Parameters**

Depending on the chart type, the range and domain axis may be customised. These values are automatically generated based on the data but can be overridden by specifying one or more more of these parameters.

- **rangeAxisLowerBound** — range axis lower bound.
- **rangeAxisUpperBound** — range axis upper bound
- **rangeAxisTickUnit** — range axis units between axis tick marks
- **rangeAxisLabelAngle** — angle for the range axis label in degrees
- **domainAxisLowerBound** — domain axis lower bound. For a date axis, this value must be expressed in the date format specified by the dateFormat parameter. (Only used in XY Plots, standard charts will have no effect)
- **domainAxisUpperBound** — domain axis upper bound. For a date axis, this value must be expressed in the date format specified by the dateFormat parameter. (Only used in XY Plots, standard charts will have no effect)
- **domainAxisTickUnit** — domain axis units between axis tick marks. For a date axis, this value represents a count of the units specified in the timePeriod parameter. The time period unit can be overridden by specifying a trailing character: y for years, M for months, d for days, h for hours, m for minutes, s for seconds, u - milliseconds. (Only used in XY Plots, standard charts will have no effect)
- **domainAxisLabelAngle** — angle for the domain axis label in degrees. (Only used in XY Plots, standard charts will have no effect)
- **categoryLabelPosition** — allows axis label text position for categories to be customised.
  - up45 - 45 degrees going upward
  - up90 - 90 degrees going upward
  - down45 - 45 degrees going downward
  - down90 - 90 degrees going downward
- **dateTickMarkPosition** — placement of the date tick mark.
  - start (default) — tick mark is at the start of the date period.
  - middle — tick mark is in the middle of the date period.
  - end — tick mark is at the end of the date period.

**Pie Chart Customisation Parameters**

- **pieSectionLabel** — Format for how pie section labels are displayed. The default is to show only the pie section key value. The format is a string with special replacement variables:
  - %0% is replaced by the pie section key.
  - %1% is replaced by the pie section numeric value.
  - %2% is replaced by the pie section percent value.
  - Example 1: "%0% = %1%" would display something like "Independent = 20"
  - Example 2: "%0% (%2%)" would display something like "Independent (20%)"
- **pieSectionExplode** — Comma separated list of pie keys that are to be shown exploded. Defaults to no exploded sections. Note: requires jFreeChart version 1.0.3 or higher.

**Attachment Parameters**

These are advanced options that can be used for chart versioning, to enable automation and to improve performance. Use these options carefully! Normally, the chart image is regenerated each time the page is displayed. These options allow for the generated image to be saved as an attachment and have subsequent access re-use the attachment. This can be useful especially when combined with the Cache Plugin to improve performance. Depending on the options chosen, chart images can be versioned for historical purposes.

- **attachment** — Chart image will be saved in a attachment. This advanced capability is for automation or use in combination with the cache macro. For attachment to be used, the user must be authorised to add attachments to the page specified.
  - attachmentName.png — The chart is saved as an attachment to the current page.
  - space:page*attachmentName.png — The chart is saved as an attachment to the space indicated.
- **attachmentVersion** — Defines the the versioning mechanism for saved charts.
  - new (default) Creates new version of the attachment.
  - replace — Replaces all previous versions of the chart. To replace an existing attachment, the user must be authorized to remove attachments for the page specified.
  - keep — Only saves a new attachment if an existing export of the same name does not exist. An existing attachment will not be changed or updated.
- **attachmentComment** — Comment used for a saved chart attachment.
- **thumbnail** — Default is false. If true, the chart image attachment will be shown as a thumbnail.
Macros known to be allowed in the body of the chart macro

- Include Page Macro — to include a page containing data tables
- SQL Plugin — to generate chart data using SQL select statements, note multiple sql macros are allowed in the same body.
- CSV Macro — to provide chart data from comma separated values (csv)
- Java Scripting Plugin — to generate chart data using Java code
- Excel Plugin — to provide chart data from an Excel spreadsheet
- Layout Macros — the section and column macros can be used starting with version 1.7

Macros known to cause problem if included in the body of the chart macro

If you use the section, column, scrollbar, or other advanced formatting macros in the body of the chart macro, then you must use the tables parameter to identify the tables that are to be used for chart data. This is due to the fact that these macros produce tables causing the data tables to be lower level sub-tables. The easiest approach is to assign an id to the data table and then explicitly list it in the tables parameter of the chart macro. The id of the table can be set using various macros that have Common table capabilities.

Examples

Time Series Chart

What you need to type

```markdown
{chart:type=timeSeries|dateFormat=MM/yyyy|timePeriod=Month|
dataOrientation=vertical|rangeAxisLowerBound=0|domainaxiserotateticklabel=true}

<table>
<thead>
<tr>
<th>Month</th>
<th>Revenue</th>
</tr>
</thead>
<tbody>
<tr>
<td>1/2005</td>
<td>31.8</td>
</tr>
<tr>
<td>2/2005</td>
<td>41.8</td>
</tr>
<tr>
<td>3/2005</td>
<td>51.3</td>
</tr>
<tr>
<td>4/2005</td>
<td>33.8</td>
</tr>
<tr>
<td>5/2005</td>
<td>27.6</td>
</tr>
<tr>
<td>6/2005</td>
<td>49.8</td>
</tr>
<tr>
<td>7/2005</td>
<td>51.9</td>
</tr>
<tr>
<td>8/2005</td>
<td>77.3</td>
</tr>
<tr>
<td>9/2005</td>
<td>73.8</td>
</tr>
<tr>
<td>10/2005</td>
<td>97.6</td>
</tr>
<tr>
<td>11/2005</td>
<td>101.2</td>
</tr>
<tr>
<td>12/2005</td>
<td>113.7</td>
</tr>
</tbody>
</table>
```

What you will get

![Time Series Chart](chart)

XY Line Chart

What you need to type

```markdown
{chart}

<table>
<thead>
<tr>
<th>Month</th>
<th>Expenses</th>
</tr>
</thead>
<tbody>
<tr>
<td>1/2005</td>
<td>41.1</td>
</tr>
<tr>
<td>2/2005</td>
<td>43.8</td>
</tr>
<tr>
<td>3/2005</td>
<td>45.3</td>
</tr>
<tr>
<td>4/2005</td>
<td>45.0</td>
</tr>
<tr>
<td>5/2005</td>
<td>44.6</td>
</tr>
<tr>
<td>6/2005</td>
<td>43.8</td>
</tr>
<tr>
<td>7/2005</td>
<td>51.8</td>
</tr>
<tr>
<td>8/2005</td>
<td>52.3</td>
</tr>
<tr>
<td>9/2005</td>
<td>53.8</td>
</tr>
<tr>
<td>10/2005</td>
<td>55.6</td>
</tr>
<tr>
<td>11/2005</td>
<td>61.2</td>
</tr>
<tr>
<td>12/2005</td>
<td>63.7</td>
</tr>
</tbody>
</table>
```

What you will get

![XY Line Chart](chart)
What you need to type

{chart:type=xyline}

<table>
<thead>
<tr>
<th></th>
<th>12</th>
<th>14</th>
<th>23</th>
</tr>
</thead>
<tbody>
<tr>
<td>Revenue</td>
<td>41.1</td>
<td>31.8</td>
<td>12.4</td>
</tr>
<tr>
<td>Expense</td>
<td>31.1</td>
<td>41.8</td>
<td>43.6</td>
</tr>
</tbody>
</table>

{chart}

What you will get

XY Bar Chart

What you need to type

{chart:type=xybar|opacity=60}

</tbody>
</table>
### Cheese Macro

The **Cheese Macro** simply displays the words "I like cheese!"

You can use this macro to test the Confluence macro functionality.

#### Usage with the Macro Browser

To insert the cheese macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'insert' to put the macro into the page.

Once you've found the cheese macro, click 'insert' to add it to your page.
Usage with the Wiki Markup Editor

</thead>
<tbody>
<tr>
<td>{children:all=true}</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Child Page 1</td>
</tr>
<tr>
<td></td>
<td>• Grandchild</td>
</tr>
<tr>
<td></td>
<td>• Child Page 2</td>
</tr>
</tbody>
</table>

**Parameters**
Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in **Bold** text, while their equivalents in wiki markup are indicated in *(bracketed)* text. If the latter is not shown, then in wiki markup, the parameter’s name should be omitted and only its value should be added immediately after the colon symbol (:).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Show Descendants <em>(all)</em></td>
<td>false</td>
<td>Display all descendents</td>
</tr>
<tr>
<td>Parent Page <em>(page)</em></td>
<td>current</td>
<td>Specify which page to display children for in a current space or in a different space. If the page parameter is ?, then the macro will list all the current space’s top-level pages i.e. those without parents. If the page parameter is a space key followed by a colon (e.g children:page=DOC:), then the top-level pages of that space will be listed.</td>
</tr>
<tr>
<td>Depth of Descendants <em>(depth)</em></td>
<td>none</td>
<td>Specify the depth of descendents to display. If your (children) macro includes both ‘all=true’ and ‘depth=X’ parameter-value combinations where X is a number, ‘all=true’ takes precedence. If an ‘all=false’ and ‘depth=X’ parameter-value combination is used, ‘depth=X’ takes precedence.</td>
</tr>
<tr>
<td>Number of Children <em>(first)</em></td>
<td>none</td>
<td>Restrict the number of children displayed at the top level</td>
</tr>
<tr>
<td>Heading Style <em>(style)</em></td>
<td>none</td>
<td>Specify the style in which descendents are displayed</td>
</tr>
<tr>
<td>Include Excerpts <em>(excerpt)</em></td>
<td>false</td>
<td>Display the child pages’ excerpts, if they exist</td>
</tr>
<tr>
<td>Sort Children By <em>(sort=creation)</em> <em>(sort=title)</em> <em>(sort=modified)</em></td>
<td>Manual if manually ordered, otherwise alphabetical</td>
<td>The ‘sort’ attribute is an optional attribute that allows you to configure how the children are sorted. Specify ‘creation’ to sort by content creation date, ‘title’ to sort alphabetically on title and ‘modified’ to sort of last modification date.</td>
</tr>
<tr>
<td>Reverse Sort <em>(reverse)</em></td>
<td>false</td>
<td>Use this parameter in conjunction with the ‘sort’ parameter described above. Set ‘reverse=true’ to change the sort from ascending to descending order.</td>
</tr>
</tbody>
</table>

**Examples**

1. Display all descendents of the page

   `{children:all=true}`

2a. Specify which page to display children for

   `{children:page=page-name}`

2b. Specify which page in a different space to display children for

   `{children:space-key:page-name}`

3. Specify the depth of descendents

   `{children:depth=2}`

4. Restrict the number of children displayed at the top level
5. Specify the style in which descendents are displayed
Choose from heading levels h1 to h6.

{children:depth=1|style=h3}

6. Display the child pages’ excerpts, if they exist

{children:depth=2|excerpt=true}

7. Sort children by modification date

{children:sort-creation|reverse=true}

- Usage with the Wiki Markup Editor
- Parameters
- Examples

**Usage with the Macro Browser**

To insert the code block macro into a page using the Macro Browser,
1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.

2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.

3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'insert' to put the macro into the page.

Once you've found the code block macro, click 'insert' to add it to your page.

Usage with the Wiki Markup Editor

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>```code`</td>
<td></td>
</tr>
<tr>
<td>public static void main(String[] args)  { ```code`</td>
<td></td>
</tr>
</tbody>
</table>

Parameters

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

⚠️ Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in **Bold** text, while their equivalents in wiki markup are indicated in (bracketed) text. If the latter is not shown, then in wiki markup, the parameter’s name should be omitted and only its value should be added immediately after the colon symbol ( : ).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Code Language</strong></td>
<td>Java</td>
<td>Specifies the programming language for syntax highlighting. The default language is <strong>Java</strong> but you can specify JavaScript, ActionScript, XML, HTML or SQL instead.</td>
</tr>
</tbody>
</table>

Be aware that any white space contained between the `{code}` commands is not manipulated in any way by the Code Block Macro. This is to provide the writer with flexibility over code indentation.

⚠️ All the optional parameters of the `{panel}` macro are valid for the `{code}` macro as well.

Examples

**Example 1: Java**

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>{code}</code></td>
<td></td>
</tr>
<tr>
<td>public String getFoo() { ```code`</td>
<td></td>
</tr>
<tr>
<td></td>
<td>return foo;</td>
</tr>
<tr>
<td>}</td>
<td>} ```code`</td>
</tr>
</tbody>
</table>

Adaptavist User Guide

Take me back to the Confluence User Guide.

Color Text Macro

You can use the Color Text Macro to change the colour of a block of text. Specify the colours by name or by hexadecimal value. Coloured text appears just like the line below.

Orange coloured text renders like this.

See more information about web colours.

On this page:

- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
- Parameters
- Examples

Usage with the Macro Browser

To insert the color text macro into a page using the Macro Browser,
1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'Insert' to put the macro into the page.

Once you've found the color text macro, click 'Insert' to add it to your page.

⚠️ Exact colour results may look different depending on the browser in use.

Usage with the Wiki Markup Editor

```
{color:mycolour} ... text ... {color}
```

Parameters

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in **Bold** text, while their equivalents in wiki markup are indicated in (bracketed) text. If the latter is not shown, then in wiki markup, the parameter's name should be omitted and only its value should be added immediately after the colon symbol (:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Color Name/Hexadecimal Code (color)</td>
<td>Yes</td>
<td>None</td>
<td>Colour of text. You can use names for common colours or use the hexadecimal code for a more specific colour.</td>
</tr>
</tbody>
</table>

Examples

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>{color:red}red{color}</td>
<td>red</td>
</tr>
<tr>
<td>{color:green}green{color}</td>
<td>green</td>
</tr>
<tr>
<td>{color:blue}blue{color}</td>
<td>blue</td>
</tr>
<tr>
<td>{color:orange}orange{color}</td>
<td>orange</td>
</tr>
<tr>
<td>{color:yellow}yellow{color}</td>
<td>yellow</td>
</tr>
<tr>
<td>{color:purple}purple{color}</td>
<td>purple</td>
</tr>
<tr>
<td>{color:purple}violet{color}</td>
<td>violet</td>
</tr>
<tr>
<td>{color:#FF0000}#FF0000{color}</td>
<td>#FF0000</td>
</tr>
<tr>
<td>{color:#00FF00}#00FF00{color}</td>
<td>#00FF00</td>
</tr>
<tr>
<td>{color:#0000FF}#0000FF{color}</td>
<td>#0000FF</td>
</tr>
</tbody>
</table>

Hexadecimal colour codes use a leading hash symbol (#) then two digits for the red, green and blue values respectively. For example, the brightest red colour is shown by the code FF0000, where the first two digits (FF) are the maximum value for red (255 in decimal notation), while the green and blue digit pairs both represent the absolute minimum values at 00. Similarly, the brightest green is shown by the code 00FF00, and the brightest blue is shown by the code 0000FF. Other codes are a combination of the three, leading to the full range of colour. [More information](#)

Column Macro

The **column macro** allows you to define a set of columns across a page.

A set of columns must be defined within a vertical 'section' of a page. Hence, to display a set of columns correctly across a page, each column in the set must be inserted within a single pair of **section macro** elements. Furthermore, each column in the set is defined as a pair of column macro elements.

Once you have defined your set of columns within a pair of section macro elements, you can add content to each column by inserting your content within the body of each pair of column macro elements.
The following example in Wiki Markup, shows a set of two columns defined across a section of a page,

```
{section:border=true}
{column}The content of column one is entered within the body of the first set of column elements here.
{column}The content of column two is entered within the body of the second set of column elements here.
{section}
```

which renders on the page like this:

<table>
<thead>
<tr>
<th>Content of Column One</th>
<th>Content of Column Two</th>
</tr>
</thead>
<tbody>
<tr>
<td>The content of column one is entered within the body of the first set of column elements here.</td>
<td>The content of column two is entered within the body of the second set of column elements here.</td>
</tr>
</tbody>
</table>

On this page:
- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
- Parameters

**Usage with the Macro Browser**

To insert the column macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'Insert' to put the macro into the page.

Once you've found the column macro, click 'Insert' to add it to your page.

⚠️ One or more column macros must be inserted within a section macro to be displayed correctly on a page.

**Usage with the Wiki Markup Editor**

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>{section}</code> <code>{column}</code> Column one text goes here <code>{column}</code> Column two text goes here <code>{section}</code></td>
<td>Column one text goes here Column two text goes here</td>
</tr>
</tbody>
</table>

**Parameters**

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

⚠️ Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in **Bold** text, while their equivalents in wiki markup are indicated in *(bracketed)* text. If the latter is not shown, then in wiki markup, the parameter's name should be omitted and only its value should be added immediately after the colon symbol (:).

<td>Column Width</td>
<td>no</td>
<td>100% of the page width, divided equally by the number of (column)s in the (section)</td>
<td>The width of the column. Can be specified either in pixels (e.g. <code>{column:width=400px}</code>) or as a percentage of the available page width (e.g. <code>{column:width=50%}</code>)</td>
</tr>
</tbody>
</table>

1412
Content by User Macro

The **Content by User macro** generates a tabulated list of all current content items created by a specified Confluence user throughout a Confluence installation. These items include any existing page, comment or space created by a specified user. The table generated is divided into three columns and each item listed within it is hyperlinked directly to its corresponding page, page’s comment or space’s dashboard.

---

**Please note the following points:**

- Each item in the table is represented by the name of its page or space.
- Each comment item contains two hyperlinked components separated by a greater-than sign (>). The first hyperlink leads to the page itself while the second leads directly to the comment further down the page. The second hyperlink is represented by the name of the page, preceded by Re:

Working with Macros

Take me back to the Confluence User Guide.

**Contributors Macro**

The **Contributors macro** displays a list of Confluence users who have made a contribution of some type to a page. It can also be used to list watchers of this page.

The scope of this macro can be extended to include the immediate children or descendants of the specified page. The list of contributors can be based on people who have:

- authored or edited the page(s)
- contributed comments or added labels to the page(s), or
- are simply watching the page(s)

**Screenshot: Example list of Contributors**

- Sarah Macdon
- Edwin Dawson
- Giles Gaskell
- Rosie Jamison
- Andrew Lui
- Charles Miller

In this example, the **Display Format** parameter has been set to **list**. For more information about this macro's parameters, refer to the
Parameters section below.

On this page:

- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
- Parameters

Usage with the Macro Browser

To insert the contributors macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'insert' to put the macro into the page.

Once you’ve found the contributors macro, click 'insert' to add it to your page.

Usage with the Wiki Markup Editor

```
{contributors:include=TYPE}
```

Where TYPE refers to the type of contribution made to the current page (and optionally its descendants), or watches of these pages.

Parameters

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in **Bold** text, while their equivalents in wiki markup are indicated in *(bracketed)* text. If the latter is not shown, then in wiki markup, the parameter's name should be omitted and only its value should be added immediately after the colon symbol (:).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required in Wiki Markup?</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
</table>
| Contribution Type          | no                       | authors | The type of contribution made to a page (and optionally its descendant pages), or watches of these pages. This parameter defines which people appear in the contributors list and the statistics used to order them in the list. The allowable contribution types include:
  - authors - people who authored or have edited the page(s)
  - comments - people who have added comments to the page(s)
  - labels - people who have added labels to the page(s)
  - watches - people who are watching the page(s).
  One or more contribution types can be used. |
| Sort By (order)            | no                       | count   | The criteria used to sort the contributors in the list, based on the chosen **Contribution Type**. The allowable sort criteria include:
  - count - sorts people based on the total number of edits, or comments or labels added to the page(s)
  - name - sorts people in alphabetical order
  - update - sorts people based on when they last edited, or added a comment or label to the page(s). |
| Reverse Sort (reverse)     | no                       | false   | Reverses the order of contributors in the list, sorted by the chosen **Sort By** criterion. Used only in conjunction with the **Sort By** parameter. |
| Maximum Number of Contributors (limit) | no | no limit | Restricts the number of contributors in the list to the value specified. If no number is specified, no restriction is applied. |
| Display Format (mode)      | no                       | inline  | Displays the contributors as a comma-separated line of names *(Inline)* or as a bullet-point list *(list)*. |
Show Anonymous Contributions? (showAnonymous) | no | false | Includes people who have made anonymous contributions to a page, in the list of contributors.
---
Show Count? (showCount) | no | false | Indicate the number of times each person in the list made a contribution, based on the chosen Contribution Type.
---
Show Last Contribution Time? (showLastTime) | no | false | Indicates the last time each person in the list made a contribution, based on the chosen Contribution Type.
---
Page Name (page) | no | current | The page from which to base the contributors list and its statistics. If no Page Name and Space(s) are specified, the current page is assumed.
---
Label(s) (labels) | no | none | Restricts list of contributors to those who created these labels from the specified page(s). Separate each label with a comma.
---
Space(s) (spaces) | no | current | Specify the space key of the Confluence space which contains the specified Page Name or alternatively, specify a scope of spaces to search. Space keys are case-sensitive. This parameter also takes special values, including:
  - @global — All global spaces.
  - @personal — All personal spaces.
  - @all — All spaces in your Confluence site.

You can specify one or more space keys or special values, each of which must be separated by a comma.

If no Page Name and Label(s) are specified, all pages from the specified set of spaces are included.
---
Content Type (contentType) | no | both pages and blog posts | Used to restrict page types to either pages (pages) or blog posts (blogposts). If no value is specified in the Macro Browser, both pages and blog posts are included.
---
Blog Post Date (publishDate) | no | none | Specify the publish date for a blog post. The date format required is: YYYY/MM/DD.
---
Include Page Hierarchy (scope) | no | specified page only | Includes either the immediate children or all descendants of the specified page. If no value is indicated in the Macro Browser, only the specified page is included.
---
Show Selected Pages (showPages) | no | false | Shows a list of pages returned immediately above the list of contributors.
---
Custom "None Found" Message (noneFoundMessage) | no | default "none found" message | When no contributors are found, override the default message displayed by the macro, with this one.

Contributors Summary Macro  
Working with Macros

Take me back to the Confluence User Guide.

**Contributors Summary Macro**

The **Contributors Summary macro** displays a table of contribution-based statistics for a set of pages. These statistics can be grouped according to individual pages or individual contributors.

The default scope of this macro covers an individual page, but this can be extended to include the immediate children or descendants of a specified page. The statistics cover the following types of contributions:

- edits to the page(s)
- comments added to the page(s)
- labels added to the page(s)
- people watching the page(s)

A simple example of the Contributors macro is shown in the block below, which lists statistics on the number of times each contributor has
edited, added comments and added labels to this page.

Screenshot: Example Contributors Summary table of statistics

<table>

</table>

In this example, all default parameter settings are used. For more information about this macro's parameters, refer to the Parameters section below.

On this page:

- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
- Parameters

Usage with the Macro Browser

To insert the contributors summary macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'Insert' to put the macro into the page.

Once you've found the contributors summary macro, click 'Insert' to add it to your page.

Usage with the Wiki Markup Editor

{contributors-summary:groupby=TYPE}

Where TYPE refers to the criterion used for grouping statistics associated with the current page (and optionally its descendants). This criteria can be either contributor- or page-based.

Parameters

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in Bold text, while their equivalents in wiki markup are indicated in (bracketed) text. If the latter is not shown, then in wiki markup, the parameter's name should be omitted and only its value should be added immediately after the colon symbol (:).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required in Wiki Markup?</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Group By</td>
<td>no</td>
<td>contributors</td>
<td>Specify if the table should group contribution-based statistics by contributor or page.</td>
</tr>
</tbody>
</table>
| Columns to Display (columns) | no | edits, comments and labels | The columns that should appear in the table. The statistics or type of information presented is based on the Group By parameter (above). The allowable types of contributions include:

- `edits` — number of times the contributor has edited the page(s) or number of edits made to the page.
- `edited` — list of pages edited by the contributor or list of contributors who have edited the page.
- `comments` — number of times the contributor has added comments to the page(s) or number of comments on the page.
- `commented` — list of pages to which the contributor has added comments or list of contributors who have commented on the page.
- `labels` — number of times the contributor has added labels to the page(s) or number of labels on the page.
- `labeled` — list of pages to which the contributor has added labels or list of contributors who have added a label to the page.
- `labellist` — list of labels either added by the contributor or on the page.
- `watches` — number of pages being watched by the contributor/person or number of contributors/people watching the page.
- `watching` — list of pages being watched by the contributor/person or list of contributors/people watching the page.
- `lastupdate` — the last time a contributor made an update or the page was last updated. Valid updates can include edit, comment or label modifications to a page.

One or more columns can be used.

| Sort By (order) | no | count | The criteria used for sorting items in the table. The items sorted are based on the Group By parameter (above). The allowable sort criteria include:

- `edits` — sorts items in the table based on the total number of edits made either by a contributor or to a page.
- `name` — sorts items in the table in alphabetical order, either by contributor or page name.
- `editTime` — sorts items in the table based on when the contributor last edited a page (or a specified set of pages) or when the page was last edited.
- `update` — sorts items in the table based on when the contributor last made any contribution to a page (or a specified set of pages) or when the page last had a contribution made to it.

| Reverse Sort (reverse) | no | false | Reverses the order of items in the table, sorted by the chosen Sort By criterion. (Used only in conjunction with the Sort By parameter.)

| Maximum Number of Contributors (limit) | no | no limit | Restricts the number of items in the table to the value specified. If no number is specified, no restriction is applied.

| Show Anonymous Contributions? (showAnonymous) | no | false | Includes individuals who have made anonymous contributions to a page, in the tabulated statistics.

| Page Name (page) | no | current | The page from which to calculate the contribution-based statistics. If no Page Name and Space(s) are specified, the current page is assumed.

| Label(s) (labels) | no | none | Restrict the contribution-based statistics to these labels only. Separate each label with a comma.

| Space(s) (spaces) | no | current | Specify the space key of the Confluence space which contains the specified page name or alternatively, specify a scope of spaces to search. Space keys are case-sensitive.

This parameter also takes special values, including:

- `@global` — All global spaces.
- `@personal` — All personal spaces.
- `@all` — All spaces in your Confluence site.

You can specify one or more space keys or special values, each of which must be separated by a comma.

If no Page Name and Label(s) are specified, all pages from the specified set of spaces are included.
### Content Type

**contentType**

No both pages and blog posts

Used to restrict page types to either pages (**pages**) or blog posts (**blogposts**). If no value is specified in the Macro Browser, both pages and blog posts are included.

### Blog Post Date

**publishDate**

No none

Specify the publish date for a blog post. The date format required is: YYYY/MM/DD.

### Include Page Hierarchy

**scope**

No specified page only

Includes either the immediate children or all descendants of the specified page. If no value is indicated in the Macro Browser, only the specified page is included.

### Create Space Button Macro

The **Create Space Button Macro** renders a create space icon that links to the 'create space' page. The icon appears as rendered below.

*Screenshot: The Create Space Button in Confluence*

⚠️ To display this icon, you require 'Create Space' permission which is assigned by a site administrator from the Administration Console. See Security or contact your site administrator for more information.

**On this page:**

- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
- Parameters
- Example: Specify the size of the icon displayed

**Usage with the Macro Browser**

To insert the create space button macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'insert' to put the macro into the page.

Once you've found the create space button macro, click 'insert' to add it to your page.

**Usage with the Wiki Markup Editor**

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>{create-space-button}</code></td>
<td><img src="icon.png" alt="Create Space Button Icon" /></td>
</tr>
</tbody>
</table>

**Parameters**

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

⚠️ Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in **Bold** text, while their equivalents in wiki markup are indicated in *(bracketed)* text. If the latter is not shown, then in wiki markup, the parameter's name should be omitted and only its value should be added immediately after the colon symbol ( : ).

- Working with Macros

Take me back to the Confluence User Guide.

**Documentation Link Macro**

The **Documentation Link** macro generates a customisable text link to a page on [http://confluence.atlassian.com/](http://confluence.atlassian.com/).

This macro accepts a ‘relative link’ value and automatically prefixes this value with the URL:

- [http://confluence.atlassian.com/](http://confluence.atlassian.com/)

Hence, if you used the link value display/DOC/Working+with+Macros, the resulting URL is:

- [http://confluence.atlassian.com/display/DOC/Working+with+Macros](http://confluence.atlassian.com/display/DOC/Working+with+Macros)

Documentation Links are generated against the contents of this macro’s body text, allowing you to customise the text of this link.

For example, if you view this page’s wiki markup, you will see that this link uses the Documentation Link macro and that it leads back to the parent of this page in the Confluence ‘DOC’ space.

**On this page:**

- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
- Parameters

**Usage with the Macro Browser**

To insert the Documentation Link macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click ‘insert’ to put the macro into the page.

Once you've found the Documentation Link macro and have added the required parameter values, click 'insert' to add it to your page.

**Usage with the Wiki Markup Editor**

<table>
<thead>
<tr>
<th>Example of what you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>{doc:display/DOC/Working+with+Macros}this link(doc)</td>
<td>this link</td>
</tr>
</tbody>
</table>

**Parameters**

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.
Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in **Bold** text, while their equivalents in wiki markup are indicated in *(bracketed)* text. If the latter is not shown, then in wiki markup, the parameter's name should be omitted and only its value should be added immediately after the colon symbol (:).

<table>
<thead>
<tr>
<th>Parameter</th>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Relative Link</td>
<td>yes</td>
<td>none</td>
<td>The relative link (that is, the URL portion after <a href="http://confluence.atlassian.com/">http://confluence.atlassian.com/</a>) that leads to the required page on <a href="http://confluence.atlassian.com/">http://confluence.atlassian.com/</a>.</td>
</tr>
</tbody>
</table>

**RELATED TOPICS**

Working with Macros

Take me back to the Confluence User Guide.

**Edit in Word Link Macro**

The **Edit in Word Link Macro** allows you to display an 'Edit in Word' icon on the page, like the following image: ![Edit in Word Link Macro](image)

When a user clicks the icon, Confluence will start the 'Edit in Word' feature of the **Office Connector**. This will launch Microsoft Word as an editor for the page content.

The edit in Word link macro was created specifically for use with the **Adaptavist Theme Builder**. You may find the macro useful for themes which do not supply the 'Edit in Word' option in the Confluence 'Tools' menu.

The edit in Word link macro is just one way that Confluence can interact with Microsoft Office documents. For an overview of all Office Connector features, please refer to Working with the Office Connector.

**On this page:**

- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
- Parameters
- Troubleshooting

**Usage with the Macro Browser**

To insert the edit in Word link macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon ![Macro Browser icon](icon) on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'insert' to put the macro into the page.

Once you’ve found the edit in Word link macro, click ‘insert’ to add it to your page.

**Usage with the Wiki Markup Editor**

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>{editinwordlink}</td>
<td><img src="image" alt="Edit in Word Link Macro" /></td>
</tr>
</tbody>
</table>

When your page is in view mode, it will show an icon like the one displayed above. When a user clicks the icon, Confluence will call the **Office Connector** to allow the page to be edited in the user's Office application. For more information, see Editing a Confluence Page in an Office Application.

**Parameters**

This macro accepts no parameters.

**Troubleshooting**

Problems? Please refer to our guide to the **Office Connector limitations and known issues**.

**RELATED TOPICS**
Excerpt Include Macro

The Excerpt Include macro is used to display content from one page in another.

To use this macro, the excerpt must have been defined using the Excerpt Macro and both pages must exist in the same space.

The excerpt appears as shown below:

<table>
<thead>
<tr>
<th>Excerpt Macro</th>
</tr>
</thead>
<tbody>
<tr>
<td>A short summary of this page</td>
</tr>
</tbody>
</table>

For this example, we are taking content from a page called 'Excerpt Macro', where the excerpt tags have already been placed. The title of the page is shown at the top of the panel and the text between the remote excerpt tags is rendered as the body of the text.

On this page:

- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
- Parameters
- Examples

Usage with the Macro Browser

To insert the excerpt include macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'insert' to put the macro into the page.

Once you've found the excerpt include macro, click 'insert' to add it to your page.

Usage with the Wiki Markup Editor

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>{excerpt-include:Excerpt Macro}</td>
<td>Excerpt Macro</td>
</tr>
<tr>
<td></td>
<td>A short summary of this page</td>
</tr>
</tbody>
</table>

For this example, we are taking content from a page called 'Excerpt Macro', where the excerpt tags have already been placed.

Parameters

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in Bold text, while their equivalents in wiki markup are indicated in (bracketed) text. If the latter is not shown, then in wiki markup, the parameter's name should be omitted and only its value should be added immediately after the colon symbol (·).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nopanel (nopanel)</td>
<td>false</td>
<td>Controls whether the square panel border around the excerpt should be removed. By default, the square panel is always shown.</td>
</tr>
</tbody>
</table>

Examples

Basic example
The following code renders an excerpt from this page with default settings:

```
{excerpt-include:Excerpt Macro}
```

The excerpt appears as shown below:

<table>
<thead>
<tr>
<th>Excerpt Macro</th>
</tr>
</thead>
<tbody>
<tr>
<td>A short summary of this page</td>
</tr>
</tbody>
</table>

Removing the square panel around the excerpt

By default, the excerpt is displayed within a panel. A value of "nopanel=true" displays the excerpt without the panel.

```
{excerpt-include:Excerpt Macro|nopanel=true}
```

The excerpt then appears as shown below:

A short summary of this page

**RELATED TOPICS**

Excerpt Macro

Working with Macros

Take me back to the Confluence User Guide.

**Excerpt Macro**

The Excerpt Macro is used to mark a part of a page's content for re-use. By itself, the excerpt macro does not change the display of a page. However, defining an excerpt enables other macros such as excerpt-include and blog-posts macros to display the specified content elsewhere.

ℹ️ You can only have one excerpt for a page.

**On this page:**

- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
- Parameters

**Usage with the Macro Browser**

To insert the excerpt macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'Insert' to put the macro into the page.

Once you've found the excerpt macro, click 'Insert' to add it to your page.

**Usage with the Wiki Markup Editor**

```
{excerpt}A short summary of this page{excerpt}
```

**Parameters**

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

ℹ️ Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in **Bold** text, while their equivalents in wiki markup are indicated in *(bracketed)* text. If the latter is not shown, then in wiki markup, the parameter's name should be omitted and only its value should be added immediately after the colon symbol (:).
### Favourite Pages Macro

Use the **Favourite Pages Macro** to display a list of your favourite pages.

The favourite pages macro appears as in the following screenshot.

**Screenshot: The Favourite Pages Macro in Confluence**

---

#### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hidden</td>
<td>false</td>
<td>Controls whether the text between the excerpt tags will appear on that page when users read it.</td>
</tr>
</tbody>
</table>

**Usage with the Wiki Markup Editor**

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>{favpages}</td>
<td>Favourite Pages</td>
</tr>
</tbody>
</table>

There are currently no pages on your favourites list. You can add pages to this list by clicking 🌟 on the top right of the page.

---

**Parameters**

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.
Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in **Bold** text, while their equivalents in wiki markup are indicated in *(bracketed)* text. If the latter is not shown, then in wiki markup, the parameter’s name should be omitted and only its value should be added immediately after the colon symbol (:).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(<code>maxResults</code>)</td>
<td>5</td>
<td>Specifies the maximum number of results to be displayed.</td>
</tr>
</tbody>
</table>

### Examples

**Specify the maximum number of results to be displayed**

In this example, we limit the number of results to one only.

```
{favpages:maxResults=1}
```

### Flowchart Macro

The Flowchart Macro creates diagrams composed of shapes joined by lines using the GraphViz language. This language is extremely versatile and powerful, but you can start with a really simple example as shown below, and then gradually improve your knowledge and create more advanced diagrams easily.

#### The Flowchart Macro requires the Graphviz Plugin

To use the **Flowchart Macro**, you will need to install the Graphviz plugin onto your Confluence site. This plugin is not shipped with Confluence by default, and is not officially supported by Atlassian.

- Please read more about supported and unsupported plugins.
- You can find more information about the Graphviz plugin on the plugin documentation page.

#### Usage

1. Edit the page.
2. Switch to the Wiki Markup editor.
3. Insert two `{flowchart}` commands.
4. Between those two commands, insert a textual representation of the diagram, using the GraphViz description language.

#### Examples

These are some very basic examples of what you can achieve easily. For more advanced layouts and formatting, please refer to the resources below.

<table>
<thead>
<tr>
<th>Macro Call</th>
<th>Macro Output</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>{flowchart}</code></td>
<td>Parameters → Diagram</td>
</tr>
<tr>
<td>Parameters → Diagram</td>
<td></td>
</tr>
<tr>
<td><code>{flowchart}</code></td>
<td>Parameters → Diagram</td>
</tr>
<tr>
<td>Parameters → Diagram</td>
<td></td>
</tr>
</tbody>
</table>

Take me back to the Confluence User Guide.
(flowchart)
main -> parse -> execute
main -> init
main -> cleanup
execute -> make_string
execute -> printf
init -> make_string
main -> printf
execute -> compare
(flowchart)
GraphViz Resources

GraphViz is a powerful way of describing diagrams of any kind, using just text. There is no graphical editor, so this may not be the tool of choice for the occasional user. But if you would like to visualise your ideas regularly it is well worth reading more about the language. Have a look at the following resources on the GraphViz website, to learn more than what can be explained on this overview page.

- Gallery Of Example Diagrams
- Online Documentation
- Downloadable Introduction to GraphViz (PDF format)

Working with Macros

Gallery Macro

The Gallery Macro displays a gallery of thumbnail images in a table, based on the images attached to a Confluence page. When viewing the
page, a user can click a thumbnail image to zoom into the full-size image and then view the images as a slide show.

For more information about how your readers will view the gallery, please refer to Viewing Images as a Slide Show. See below for instructions on how to add the gallery macro to your page.

The gallery macro appears as in the screenshot below.

**Screenshot: The Gallery Macro in Confluence**

```
Some office photos, and a waterfall
```

On this page:

- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
  - Some office photos, and a waterfall
- Parameters
- Examples
  - Basic Usage, Specifying Number of Table Columns
  - Excluding an Image
  - Specifying the Images to be Included
  - Specifying a Page Name
  - Sorting the Images by File Name
  - Sorting the Images to Show Most-Recently-Modified First

**Usage with the Macro Browser**

To insert the gallery macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'insert' to put the macro into the page.

Once you've found the gallery macro, click 'insert' to add it to your page.

**Usage with the Wiki Markup Editor**

Include the following markup in your page, replacing the title with your own:

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>{gallery:title=Some office photos, and a waterfall}</code></td>
<td><code>Some office photos, and a waterfall</code></td>
</tr>
</tbody>
</table>
Some office photos, and a waterfall

Here’s an office photo

Here is the waterfall photo

Parameters

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in Bold text, while their equivalents in wiki markup are indicated in (bracketed) text. If the latter is not shown, then in wiki markup, the parameter’s name should be omitted and only its value should be added immediately after the colon symbol (:).

The full list of parameters is shown in the following table.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
</table>
### Gallery Title

**title**

Specify a title for your gallery.

### Number of Columns

**columns**

Specify the number of columns for your table.

### Images to Exclude

**exclude**

No exclusions i.e. include all the pictures on the page.

The gallery will ignore any pictures specified by `exclude=picture file name` i.e. they will not be included in the gallery. You can specify more than one picture, separated by commas. Example: `exclude=my picture.png,my picture2.gif`

### Include these Images Only

**include**

Include all the pictures on the page.

If you specifically include one or more pictures, the gallery will show only those pictures. Format is `include=picture file name`. You can specify more than one picture, separated by commas. Example: `include=my picture.png,my picture2.gif`

### Use Images in these Pages

**page**

If no page is specified, the gallery displays the images attached to the page containing the macro. Specify the title of the page which contains the images you want displayed. If the page is in the same space as the page containing the macro, use the format `page=My Page`. To specify a page in a different space, use `page=SPACEKEY:My Page Name`, such as `page=DOC:Gallery Macro`

### Reverse Sort

**reverseSort**

Nothing, i.e. sort order is ascending

Used in conjunction with `sort` parameter above. Use `reverseSort` to reverse the sort order, from ascending to descending.

### Sort Images By

**sort**

None i.e. the sort order is unspecified and therefore unpredictable.

Specify an attribute to sort the images by that attribute. Sort order is ascending, unless you specify the `reverseSort` parameter (see below). Options are:

- `name` – file name.
- `comment` – comment linked to the attached file.
- `date` – date/time last modified.
- `size` – size of the attached file.

---

If the actual name of an attachment file or page contains a comma, you can refer to it in the `exclude`, `include`, or `page` parameters above by enclosing it in single or double quotes, for example "this,that.jpg", theother.png.

### Considerations for using the gallery macro

- The images shown in the gallery are taken from the files attached to the Confluence page. You can also specify a different page where the attachments are located. For information about attaching images to a page, see [Attaching Files to a Page](#).
- The comments below the images are drawn from the comments on the attachments. For information about adding comments to attachments, see [Attaching Files to a Page](#).
- By default, the gallery will include all the images attached to the page. You can also exclude or include images using parameters as described below.
- Only the following file formats are supported: `gif`, `png`, `jpeg`. The `bmp` format is not supported.
- You can sort your images into a particular order — see details below.
- You can specify a title for the gallery and also configure how many columns you want for the table in which your images are displayed. See below for details of the parameters to use.
- Read the rest of this page for more information.

### Examples

#### Basic Usage, Specifying Number of Table Columns

```markdown
{gallery:title=Some office photos, and a waterfall|columns=3}
```

#### Excluding an Image

```markdown
{gallery:title=Some office photos, without the waterfall|exclude=waterfall.jpg}
```

#### Specifying the Images to be Included

The macro code below will show only two images: 'office1.jpg' and 'waterfall.jpg'.

```markdown
{gallery:title=One office photo, and a waterfall|include=office1.jpg,waterfall.jpg}
```
Specifying a Page Name

By default, the images shown in the gallery are taken from the files attached to the Confluence page which contains the macro. You can also specify a different page where the attachments are located. For information about attaching images to a page, see Attaching Files to a Page.

The macro code below expects that the images are attached to a page called 'Gallery of Pictures', in the same space as the page containing the macro.

```
{gallery:title=Some office photos, and a waterfall|page=Gallery of Pictures}
```

Below, we specify a page in a different space.

```
{gallery:title=Some office photos, and a waterfall|page=DOC:Gallery of Pictures}
```

Combining the `page` and the `include` parameters, the code below will show only the two images specified, where the images are held as attachments on a different page.

```
{gallery:title=One office photo, and a waterfall|page=Gallery of Pictures|include=office1.jpg,waterfall.jpg}
```

Sorting the Images by File Name

```
{gallery:title=Some office photos, and a waterfall|sort=name}
```

Sorting the Images to Show Most-Recently-Modified First

```
{gallery:title=Some office photos, and a waterfall|sort=date|reverseSort}
```

Working with Macros

Global Reports Macro

The Global Reports Macro renders a list of links to global reports.

This includes a list of all orphaned pages in the site, a list of all undefined links in the site and RSS feeds for new pages and news items.

The global reports macro appears as shown in the screenshot below.

Screenshot: The Global Reports Macro in Confluence

On this page:

- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
- Parameters
- Examples
Usage with the Macro Browser

To insert the global reports macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'insert' to put the macro into the page.

Once you've found the global reports macro, click 'insert' to add it to your page.

Usage with the Wiki Markup Editor

<table>
<thead>
<tr>

<td>Find all pages that aren't linked from anywhere.</td>
</tr>
<tr>
<td></td>
<td>Find all undefined pages.</td>
</tr>
<tr>
<td></td>
<td>RSS Feed for new pages and blogs.</td>
</tr>
</tbody>
</table>

Parameters

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in **Bold** text, while their equivalents in wiki markup are indicated in *(bracketed)* text. If the latter is not shown, then in wiki markup, the parameter's name should be omitted and only its value should be added immediately after the colon symbol (:).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Width of Table</strong> (width)</td>
<td>99%</td>
<td>Specifies the width of the table in which the links are displayed.</td>
</tr>
</tbody>
</table>

Examples

Specify the width of the table in which the links are displayed

```
{global-reports : width=50%}
```

By default, the table width is set to 99%.

**HTML Include Macro**

The **HTML Include** macro allows you to include the contents of an external HTML file into a Confluence page.

**CAUTION: Including unknown HTML inside a webpage is dangerous.**
HTML can contain active scripting components. This means that it would be possible for a malicious attacker to present a user of your site with script that their web browser would believe came from you. Such code could be used, for example, to steal a user's authentication cookie and give the attacker their Confluence login password.
Usage

To embed an external page, type the following Wiki Markup code:

```html-include:url=http://www.example.com
```

Troubleshooting

- The HTML Include macro will only be available if it has been enabled by your Confluence administrator. Also, your Confluence Administrator can define a whitelist of trusted URLs. You will see an error message on the Confluence page, if the included URL is not in the whitelist.
- You can only use the HTML include macro for pages with absolute links. If you use the macro to include an HTML page that has relative links, navigating those links in the wiki results in a 'Page Not Found' error. See CONF-6567.

**IM Presence Macro**

The IM Presence Macro indicates graphically when a contact is signed into an Instant Messaging (IM) service. The IM presence macro appears as a small icon on the page, like this image: ![Online Now](https://example.com) - Online Now

**On this page:**

- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
- Parameters
  - RELATED TOPICS

**Usage with the Macro Browser**

To insert the IM presence macro into a page using the Macro Browser,
1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'Insert' to put the macro into the page.

Once you've found the IM presence macro, enter values for 'User ID/Screen Name' and select the service from the drop-down list. Finally, click 'Insert' to add the macro to your page.

Usage with the Wiki Markup Editor

The following instant messaging services are supported:
- AOL Instant Messenger (AIM)
- Google Talk (GTalk)
- IBM Lotus Sametime (Sametime)
- ICQ
- Skype
  - Skypeme (a status mode for Skype)
- Wildfire (also known as OpenFire)
- Yahoo! Messenger (YIM).

### Yahoo! Presence Macro

### Include Page Macro

The Include Page Macro allows you to display the contents of one Confluence page in another.

To display part of a page rather than include the whole page, use the Excerpt Macro and the Excerpt Include Macro.

To display a page's contents, you require 'View' permission for that page. This is assigned by a space administrator from the Space Administration screens. See Space Permissions or contact your Confluence space administrator for more information.

If the name of the included page is changed after you have written the macro, the page name does not change automatically in the macro. In the event of that happening, you will need to change the page name manually in the macro parameters.

### On this page:

- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
- Parameters
- Example

#### Usage with the Macro Browser

To insert the include page macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'insert' to put the macro into the page.

Once you've found the include page macro, click 'insert' to add it to your page.

### Usage with the Wiki Markup Editor

Where 'Sample Include Page' is the title of the page whose contents you want to display:

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
</table>

1435
Start of sample page content
End of sample page content

### Parameters

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

> Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in **Bold** text, while their equivalents in wiki markup are indicated in *(bracketed)* text. If the latter is not shown, then in wiki markup, the parameter's name should be omitted and only its value should be added immediately after the colon symbol (:).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Page to Include</strong></td>
<td>None</td>
<td>This is the name of the Confluence page you want to include in the current page. If the page you wish to include is located in another space, precede the name of the page with the space key value and ensure that the two values are separated by a colon. For example, <strong>DOC:Include Page Macro</strong>.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The space key value is case-sensitive.</td>
</tr>
</tbody>
</table>

Once the desired page is set, there are no further parameters for this macro.

### Example

**To display contents of a page located in another space**

Use the following code, where '**DS**' is the spacekey of the other space and 'Confluence Overview' is the name of the page you want to display.

```
{include:DS:Confluence Overview}
```

> You can include pages from personal spaces using **~username** as the space key.

JIRA Issues Macro

JIRA is the issue tracking and project management system supplied by Atlassian. The Jira Issues macro allows you to display a list of issues from a JIRA site within a page in Confluence.

In other words, if you have your own JIRA site, your Confluence page can show a list of issues from your JIRA project. You can also show a list of issues from any JIRA site to which you and your readers have access.

*Screenshot: Example of JIRA Issues shown on a Confluence page*
On this page:

- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
- Displaying a List of JIRA Issues on a Confluence Page
- Parameters
- Issues Displayed a Page at a Time
- Example
- Displaying Issues which have Restricted Viewing
- Troubleshooting

Usage with the Macro Browser

To insert the JIRA issues macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'insert' to put the macro into the page.

Once you've found the JIRA issues macro, click 'insert' to add it to your page.

Usage with the Wiki Markup Editor

The basic syntax is:

```
{jiraissues:url=<URL of your JIRA XML view>}
```

Displaying a List of JIRA Issues on a Confluence Page
Step 1 — Obtain the URL of the Issue Filter

1. Log in to your JIRA system.
2. Go to the 'Issues' screen and create a new filter. Do not modify an existing filter.
3. Set up your search parameters and use 'View' to check the issues returned.
4. Once the filter is finished, go to the Filter's 'View' tab/section in the top-left area of the JIRA interface.
5. Copy the XML link. To do this, follow the appropriate steps below:
   a. If you are using JIRA 4.0.x or later:
      - Click the 'Views' menu, right-click the 'XML' item and copy the XML link.
   b. If you are using JIRA 3.13.x or earlier:
      a. Locate the 'Current View' links section (see example below) and find the 'XML' link.
      b. Copy the 'XML' link to your clipboard.

Step 2 — Embed the Issue Filter URL onto your Confluence Page

1. Log in to your Confluence system.
2. Edit the page where you wish to display the list of JIRA issues.
3. Type the following text into a new line at the appropriate location:

```
{jrissues:url=CONTENT}
```
4. Replace "CONTENT" with the JIRA filter URL from your clipboard.
5. Customise the macro output by adding optional parameters. See below.
6. Save the Confluence page.

Parameters

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in Bold text, while their equivalents in wiki markup are indicated in (bracketed) text. If the latter is not shown, then in wiki markup, the parameter’s name should be omitted and only its value should be added immediately after the colon symbol (:).

The JIRA Issues macro allows the following parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Anonymous Retrieval</strong></td>
<td>no</td>
<td>false</td>
<td>If this parameter is set to 'true', JIRA will return only the issues which allow unrestricted viewing i.e. the issues which are visible to anonymous viewers, as determined by JIRA’s viewing restrictions. If this parameter is omitted or set to 'false', then the results depend on how your administrator has configured the communication between JIRA and Confluence. By default, Confluence will show only the JIRA issues which the user is authorised to view. See more details below.</td>
</tr>
<tr>
<td><strong>(anonymous)</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>(baseurl)</strong></td>
<td>no</td>
<td></td>
<td>The value of the ‘url’ parameter</td>
</tr>
<tr>
<td><strong>JIRA Field Columns to Display</strong></td>
<td>no</td>
<td></td>
<td>By default, the following columns are shown:</td>
</tr>
<tr>
<td><strong>(columns)</strong></td>
<td></td>
<td></td>
<td>- type</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- key</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- summary</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- assignee</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- reporter</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- priority</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- status</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- resolution</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- created</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- updated</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- due</td>
</tr>
<tr>
<td><strong>Display Total Numbers Only</strong></td>
<td>no</td>
<td>false</td>
<td>If this parameter is set to 'true', the issue list will show the number of issues in JIRA. The count will be linked to your JIRA site.</td>
</tr>
<tr>
<td><strong>(count)</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Cache</strong></td>
<td>no</td>
<td>on</td>
<td>The macro maintains a cache of the issues which result from the JIRA query. If the ‘cache’ parameter is set to ‘off’, the relevant part of the cache is cleared each time the macro is reloaded. (The value ‘false’ also works and has the same effect as ‘off’.)</td>
</tr>
<tr>
<td><strong>(cache)</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Height</strong></td>
<td>no</td>
<td>480</td>
<td>The height in pixels of the table displaying the JIRA issues. Note that this height specification is ignored in the following situations:</td>
</tr>
<tr>
<td><strong>(height)</strong></td>
<td></td>
<td></td>
<td>- If you set the ‘renderMode’ parameter (see below) to ‘static’.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- When the JIRA issues are displayed in a PDF or Word document, in an email message or in an RSS feed.</td>
</tr>
<tr>
<td><strong>(renderMode)</strong></td>
<td>no</td>
<td></td>
<td>By default, the JIRA Issues macro offers a dynamic display with the following features:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- Click the column headers to sort the output.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- Drag and drop the columns into a different order.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- Temporarily remove a column from the display.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- View a page of issues at a time, for faster response times.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Set the ‘renderMode’ parameter to ‘static’ if you want to disable the dynamic display features.</td>
</tr>
<tr>
<td><strong>Title</strong></td>
<td>no</td>
<td>JIRA Issues</td>
<td>You can customise the title text at the top of the JIRA issues table with this parameter. For instance, setting the title to ‘Bugs-to-fix’ will replace the default ‘JIRA Issues’ text. This can help provide more context to the list of issues displayed.</td>
</tr>
</tbody>
</table>

## URL (url)

<table>
<thead>
<tr>
<th>parameter</th>
<th>type</th>
<th>value</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>url</td>
<td>url</td>
<td>none</td>
<td>The URL of the XML view of your selected issues in JIRA Issue Navigator. Note: If the URL in the 'url' parameter does not contain a tempMax argument, then the value of tempMax will default to 500. If your JIRA server is version 3.12 or earlier, this means that the JIRA Issues macro will return a maximum of 500 issues. If your JIRA server is version 3.13 or later, a value of 500 means that the JIRA Issues macro will return a maximum of 500 issues per page.</td>
</tr>
</tbody>
</table>

## Width (width)

<table>
<thead>
<tr>
<th>parameter</th>
<th>type</th>
<th>value</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>width</td>
<td>width</td>
<td>100%</td>
<td>The width of the table displaying the JIRA issues. Can be indicated either as a percentage (%) or in pixels (px).</td>
</tr>
</tbody>
</table>

### Issues Displayed a Page at a Time

If you are using **JIRA 3.13 or later**, the JIRA Issues macro will retrieve and show a 'page' of issues at a time. The buttons underneath the table allow you to move to the next or previous page, or to the start or end of the list. The number of issues retrieved per page is determined by the url parameter — see the description of the macro parameters above.

If your version of JIRA is **3.12 or earlier**, the JIRA Issues macro will retrieve all the issues at once and display them as a single 'page'.

### Example

Below is an example of some macro markup code, requesting a list of issues from the Atlassian public JIRA site:

```
{ jiraissues:anonymous=true|url= http://jira.atlassian.com/sr/jira.issueviews:searchrequest-xml/temp/SearchRequest.xml?&query=jiraissues&summary=true&description=true&body=true&pid=10470&tempMax=10 |columns=type;key;summary }
```

The example code contains three parameters (see above parameter table for their meanings):

- anonymous=true
- url=<a long URL derived from the XML view of a JIRA filter>
- columns=type;key;summary

Below are the results of the above macro markup, displayed on this Confluence page:

<table>
<thead>
<tr>
<th>JIRA Issues (10 issues)</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
</tr>
<tr>
<td>CONF-1181</td>
</tr>
<tr>
<td>CONF-4472</td>
</tr>
<tr>
<td>CONF-3729</td>
</tr>
<tr>
<td>CONF-6878</td>
</tr>
<tr>
<td>CONF-2711</td>
</tr>
<tr>
<td>CONF-1595</td>
</tr>
<tr>
<td>CONF-4897</td>
</tr>
<tr>
<td>CONF-854</td>
</tr>
<tr>
<td>CONF-5303</td>
</tr>
<tr>
<td>CONF-11829</td>
</tr>
</tbody>
</table>

### Displaying Issues which have Restricted Viewing

Maybe your JIRA instance is not visible to anonymous visitors — everyone has to log in before they can see JIRA issues. Or maybe some of the JIRA issues are restricted to viewing by certain users only. This section explains how to handle JIRA issues that have restricted viewing.

**Using Confluence-to-JIRA Trusted Communication (Recommended)**

For **Confluence 2.7.0 and later** and **JIRA 3.12 and later**, your administrator can set up trusted communication between Confluence and JIRA. The entire process is described in the Confluence Administrator's Guide. Provided that your administrator has set up trusted communication, you don't need to add any extra parameters. Confluence and JIRA will work out the security between them, ensuring that the user will see only the issues they are authorised to see. Read the section below if you want more detail.
Remove the username and password from your macro markup code

Prior to Confluence 2.7, you needed to include a username and password in the macro markup code if you wanted to display JIRA issues which had restricted viewing. Once your administrator has set up trusted communication between Confluence and JIRA, you no longer need to include a username and password in the markup code for your JIRA macros.

The following options are available for determining the issues which will be retrieved from JIRA and displayed on the Confluence page:

<table>
<thead>
<tr>
<th>What you want to do</th>
<th>Macro parameter</th>
<th>URL parameter</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Display the JIRA issues which the logged-in user is authorised to see. And if the user is not logged in, display only issues which allow unrestricted viewing.</td>
<td></td>
<td></td>
<td>Do not specify any authentication parameters. In this case, the behaviour depends on the way your administrator has set up trusted communication between JIRA and Confluence. Here is a summary of the behaviour. If trusted communication is enabled, the authorisation will work seamlessly. When a logged-in user views your page, they will see only the JIRA issues they are allowed to see. And if they are not logged in, they will see only the issues which allow unrestricted viewing. If trusted communication is disabled, the Confluence page will show only the JIRA issues which allow unrestricted viewing.</td>
</tr>
<tr>
<td>Ensure that Confluence will display only the JIRA issues which allow unrestricted viewing.</td>
<td>anonymous</td>
<td></td>
<td>Regardless of who the user is (logged in or not), the Confluence page will show only anonymously-visible issues. Confluence will not attempt to set up a trusted communication link with JIRA in this case.</td>
</tr>
<tr>
<td>Use a pre-determined username and password to access the JIRA issues.</td>
<td></td>
<td>&amp;os_username=MYNAME&amp;os_password=MYPASSWORD</td>
<td>Not recommended. Prior to Confluence 2.7, this was the only way of displaying issues with restricted viewing. For Confluence 2.7 and later, this method will still work. Confluence will not attempt to set up a trusted communication link with JIRA in this case.</td>
</tr>
</tbody>
</table>

Specifying Username and Password in the JIRA URL (Not Recommended)

If you have not set up trusted communication between JIRA and Confluence and if your JIRA issues have restricted viewing (i.e. JIRA requires a login before allowing access to the issues), then you need to type a JIRA username and password into the macro markup code and save it onto the Confluence page.

Append the following parameters to the end of the search URL:

```
&os_username=MYNAME&os_password=MYPASSWORD
```

where MYNAME is a JIRA username and MYPASSWORD is the corresponding password for that username. This username and password should not include an ampersand (&) symbol.

Troubleshooting

HTTPS

The JIRA Issues macro can access a JIRA instance running under SSL as long as the Confluence server is set to accept the JIRA SSL certificate. Refer to the Confluence Knowledge Base article for more information about problems connecting to SSL services.

JIRA Portlet Macro

Working with Macros

In the Administrator's Guide:

- Configuring JIRA with Confluence
- Setting Up Trusted Communication between JIRA and Confluence

Take me back to the Confluence User Guide.

JIRA Portlet Macro

The JIRA Portlet Macro allows you to display a JIRA dashboard portlet on a Confluence page. JIRA is the issue tracking and project management system supplied by Atlassian.

On this page:

- Using JIRA 4.0
- Using JIRA 3.x
  - Obtaining the JIRA Portlet URL
  - Usage with the Macro Browser
  - Usage with the Wiki Markup Editor
  - Parameters
  - Example (for JIRA 3.13 or earlier)
  - Displaying Issues which have Restricted Viewing
    - Using Confluence-to-JIRA Trusted Communication
  - Troubleshooting
    - Ideas for new features or want more tips?
    - Logging Bugs and Requesting Support
    - Known Limitations when used with JIRA Calendar

Using JIRA 4.0

Please note the following if you intend to upgrade or have already upgraded your JIRA server to JIRA 4.0:

Setting up new JIRA portlets will not work when using Confluence 3.0 or earlier and JIRA 4.0.

Bear in mind that your existing JIRA portlet macros based on earlier versions of JIRA will continue to work in Confluence as they will still be functional in JIRA 4.0. However, due to architectural changes in JIRA 4.0, the ability to create new JIRA 4.0 portlet macros in Confluence 3.0 or earlier is not available. Please refer to JIRA-19285 and JIRA-18521 for more information.

If you would like the ability to create new JIRA 4.0 portlet macros in Confluence 3.0 or earlier, please vote for JIRA-18521. However, we intend to resolve this issue in a future release of Confluence.

Using JIRA 3.x

The JIRA portlet macro appears as shown in the screenshot below.

Screenshot: The JIRA Portlet Macro in Confluence

Obtaining the JIRA Portlet URL

The JIRA portlet macro requires a URL of the JIRA portlet content you wish to show on a Confluence page.

To obtain the JIRA portlet URL,
1. Log in to your JIRA system.
2. Add the portlet you wish to include in Confluence to your JIRA dashboard. (Once you have copied the portlet's URL into Confluence, you can remove it from your JIRA dashboard.)
3. Click 'On' beside 'Configure' on your JIRA dashboard. (If you don't see this link, you need to click the 'Manage Portal' link, click the 'Configure' button and then return to the dashboard.)
4. Right-click the title located at the top-left corner of the portlet and copy its link location. See Screenshot 1.

**Screenshot 1: Copy link location**

![Screenshot 1: Copy link location](image)

**Usage with the Macro Browser**

To insert the JIRA portlet macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'Insert' to put the macro into the page.

Once you have found the JIRA portlet macro, paste your copied JIRA portlet URL into the JIRA Portlet URL field and then click 'Insert' to add it to your page.

**Usage with the Wiki Markup Editor**

To insert the JIRA portlet macro into a page using the Wiki Markup editor,

1. Log in to your Confluence system.
2. Paste the copied JIRA portlet URL at the end of the url parameter in a {jiraportlet} macro on your Confluence page.

**Parameters**

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>JIRA Portlet URL (url)</td>
<td>yes</td>
<td>none</td>
<td>URL of the JIRA portlet, as described above. Certain JIRA portlets may require user authentication details in order to display their content. Hence you may need to append: &amp;os_username=yourJiraUsername&amp;os_password=yourJiraPassword to the end of this url.</td>
</tr>
<tr>
<td>Anonymous Retrieval (anonymous)</td>
<td>no</td>
<td>false</td>
<td>For Confluence 2.7.0 and later. If this parameter is set to 'true', JIRA will return only the issues which allow unrestricted viewing i.e. the issues which are visible to anonymous viewers, as determined by JIRA's viewing restrictions. If this parameter is omitted or set to 'false', then the results depend on how your administrator has configured the communication between JIRA and Confluence. By default, Confluence will show only the JIRA issues which the user is authorised to view. See more details below.</td>
</tr>
</tbody>
</table>
Example (for JIRA 3.13 or earlier)

Below is an example of some macro markup code, requesting a portlet from the Atlassian public JIRA site:

```plaintext
```

Below are the results of the above macro markup, displayed on this Confluence page:

Statistics: **Confluence** (Fix For Versions (non-archived))

Total Issues: 5,490

Displaying Issues which have Restricted Viewing

This section explains how to handle JIRA issues that have restricted viewing. Maybe your JIRA instance is not visible to anonymous visitors - everyone has to log in before they can see JIRA issues. Or maybe some of the JIRA issues are restricted to viewing by certain users only.

Using Confluence-to-JIRA Trusted Communication

Your administrator can set up trusted communication between Confluence and JIRA. The entire process is described in the Confluence Administrator's Guide.

Here is a relevant extract from the above page:

- **Remove the username and password from your macro markup code**
  
  Prior to Confluence 2.7, you needed to include a username and password in the macro markup code if you wanted to display JIRA issues which had restricted viewing. Once your administrator has set up trusted communication between Confluence and JIRA, you no longer need to include a username and password in the markup code for your JIRA macros.

The following options are available for determining the issues which will be retrieved from JIRA and displayed on the Confluence page:

<table>
<thead>
<tr>
<th>What you want to do</th>
<th>Macro parameter</th>
<th>URL parameter</th>
<th>Comments</th>
</tr>
</thead>
</table>

1445
Display the JIRA issues which the logged-in user is authorised to see. And if the user is not logged in, display only issues which allow unrestricted viewing.

Do not specify any authentication parameters. In this case, the behaviour depends on the way your administrator has set up trusted communication between JIRA and Confluence. Here is a summary of the behaviour. If trusted communication is enabled, the authorisation will work seamlessly. When a logged-in user views your page, they will see only the JIRA issues they are allowed to see. And if they are not logged in, they will see only the issues which allow unrestricted viewing. If trusted communication is disabled, the Confluence page will show only the JIRA issues which allow unrestricted viewing.

Ensure that Confluence will display only the JIRA issues which allow unrestricted viewing.

anonymous

Regardless of who the user is (logged in or not), the Confluence page will show only anonymously-visible issues. Confluence will not attempt to set up a trusted communication link with JIRA in this case.

Use a pre-determined username and password to access the JIRA issues.

&os_username=MYNAME&os_password=MYPASSWORD

Not recommended. Prior to Confluence 2.7, this was the only way of displaying issues with restricted viewing. For Confluence 2.7 and later, this method will still work. Confluence will not attempt to set up a trusted communication link with JIRA in this case.

Troubleshooting

Ideas for new features or want more tips?

If you have an idea for a new feature, please log it on our JIRA site. You will also find many hints and tips on our Confluence forum. Try asking a question or sharing your ideas with other Confluence users.

Logging Bugs and Requesting Support

If you have found a bug in this macro, please log it on our JIRA site. If you encounter a problem using this macro, please raise a ticket on our Support site.

Known Limitations when used with JIRA Calendar

If you are using the JIRA Portlet macro in combination with the JIRA Calendar, paging will work only if your Confluence and JIRA sites are running on the same host. Otherwise, you see error messages like Access to restricted URI.

Reason: the Calendar portlet communicates with JIRA via AJAX requests. Because of security concerns, browsers by default do not allow requests to any host different from the one the page was originally downloaded from.

There is a workaround. If you wish, you can turn off this security check in your browser. The exact way depends on your browser version, so Google for hints.

⚠️ Please consider all implications of turning off this security check before you perform this action.

There is an existing request to develop support for proxying of the AJAX requests from Confluence to JIRA. If you need this feature, please vote for this issue: JCAL-64.

JUnit Report Macro

The **JUnit Report Macro** displays a summary of JUnit test results from a directory accessible by the Confluence server. JUnit is a unit testing framework which allows programmers to ensure that individual units of Java source code are functioning correctly.

The JUnit report macro appears as shown in the screenshot below.

**Screenshot: The JUnit Report Macro in Confluence**

<table>
<thead>
<tr>
<th>Test</th>
<th>Time</th>
<th>Messages</th>
</tr>
</thead>
<tbody>
<tr>
<td>MoneyTest</td>
<td>00:03:391</td>
<td>Tests:Failures:Exceptions:</td>
</tr>
<tr>
<td>testAdd</td>
<td>00:03:0</td>
<td>1 0 0</td>
</tr>
</tbody>
</table>

When generating reports from JUnit, set the Apache Ant formatter to **'XML'**.

On this page:

- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
- Parameters
- Examples

### Usage with the Macro Browser

To insert the JUnit report macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'insert' to put the macro into the page.

Once you've found the JUnit report macro, fill in the URL fields and click 'insert' to add it to your page.

### Usage with the Wiki Markup Editor

To insert the JUnit report macro into a page using the Wiki Markup Editor,

Enter the `junitreport` code tags into your document as follows.

```markdown
{junitreport:directory=file:///*directory*/}
```

### Parameters

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in **Bold** text, while their equivalents in wiki markup are indicated in *(bracketed)* text. If the latter is not shown, then in wiki markup, the parameter’s name should be omitted and only its value should be added immediately after the colon symbol (:).

<table>
<thead>
<tr>
<th><strong>Parameter</strong></th>
<th><strong>Default</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Directory (URL) of your test result files (directory)</td>
<td>None</td>
<td>URL of a directory containing your test result files.</td>
</tr>
<tr>
<td>Report Detail (reportdetail)</td>
<td>'fixture'</td>
<td>Detail for report. Can be 'all', 'fixture', 'summary' or 'failuresonly'.</td>
</tr>
</tbody>
</table>

---

1447
URL of the test result XML file (url)

| None | URL of a particular test result XML file. For Confluence installations without anonymous user access, you can specify logon credentials as part of this parameter in the form of URL parameters:
|------|---------------------------------------------------------------------------------------------------------------------------------------------------
|      | • os_username — The username of a Confluence user with permission to access to the JUnit test results.                                                  |
|      | • os_password — The password of the Confluence user specified in the os_username parameter.                                                        |

(debug)

None | Shows the content of failures, as well as the error messages.

Examples

Loading JUnit reports from a local drive

```
{junitreport:directory-file:///C:/TEMP/}
```

⚠️ Must be a directory name and not the XML file itself.

Loading JUnit reports from a network drive

```
{junitreport:url=http://*host*/*path*}
```

Loading JUnit reports from a Confluence instance

```
{junitreport:url=http://yourConfluenceInstance.com/download/attachments/<page id>/file.xml}
```

Loading JUnit reports from a Confluence instance without anonymous user access

If your Confluence instance is not accessible by anonymous users, specify logon credentials with the os_username and os_password URL parameters (as part of the macro's url parameter). In this case, we are specifying a username of "admin" and a password of "admin".

```
{junitreport:url=http://yourConfluenceInstance.com/download/attachments/<page id>/file.xml?os_username=admin&os_password=admin}
```

⚠️ If you use both the directory and url parameters in the same macro, the directory will be used and the url parameter ignored.

Livesearch Macro

The Livesearch Macro allows you to add a search box to a Confluence page. When users enter a search term into the search box, Confluence will dynamically display matching results as they type.

The livesearch macro appears as shown in the screenshot below:

*Screenshot: The Livesearch Macro in Confluence*

On this page:

- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
- Parameters
- Examples
Usage with the Macro Browser

To insert the livesearch macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'insert' to put the macro into the page.

Once you've found the livesearch macro, click 'insert' to add it to your page.

Usage with the Wiki Markup Editor

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>{livesearch}</td>
<td></td>
</tr>
</tbody>
</table>

Parameters

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in Bold text, while their equivalents in wiki markup are indicated in (bracketed) text. If the latter is not shown, then in wiki markup, the parameter's name should be omitted and only its value should be added immediately after the colon symbol ( :).

The Livesearch macro allows the following parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID (id)</td>
<td>no</td>
<td>none</td>
<td>Uniquely identifies the Livesearch when there are multiple livesearch macros in one page.</td>
</tr>
<tr>
<td>Restrict to this Space Key (spaceKey)</td>
<td>no</td>
<td>all spaces</td>
<td>Specify a space key to limit the search to the given space.</td>
</tr>
</tbody>
</table>

Examples

Restricting the Search to a Single Space

The sample code below restricts the search to the space which has a space key of 'DS'.

```markdown
{livesearch:spaceKey=DS}
```

Loremipsum Macro

The Loremipsum macro displays a few paragraphs of pseudo-Latin text (more information). You can use this macro to generate some more-or-less meaningless text for demonstration purposes in pages showing a draft layout or arrangement of page elements. The text is deliberately non-meaningful so that it does not influence the viewer’s perception of the page arrangement or design.

A basic example of the Loremipsum macro is shown in the block below.

Without any parameters, the \{loremipsum\} macro generates three paragraphs. However, any number of paragraphs can be specified.

**On this page:**

- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
- Parameters

**Usage with the Macro Browser**

**To insert the Loremipsum macro into a page using the Macro Browser,**

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon \[\] on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'insert' to put the macro into the page.

Once you've found the Loremipsum macro, click 'insert' to add it to your page.

**Usage with the Wiki Markup Editor**

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
</table>

### Parameters

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in *Bold* text, while their equivalents in wiki markup are indicated in *(bracketed)* text. If the latter is not shown, then in wiki markup, the parameter’s name should be omitted and only its value should be added immediately after the colon symbol (:).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of Paragraphs</td>
<td>3</td>
<td>Displays paragraphs of pseudo-Latin (space-filler) text.</td>
</tr>
</tbody>
</table>

Apart from the number of paragraphs, there are no additional parameters for this macro.

### RELATED TOPICS

**Working with Macros**

Take me back to the *Confluence User Guide*.

### Metadata Macro

The **Metadata macro** allows you to embed metadata into pages and blog posts for presentation with the **Metadata Summary Macro**. Each metadata item consists of a field name and an associated value. When a metadata macro is rendered on a page, each metadata item is presented on a single line, starting with the name of the field, followed by its value, for example:

**Is-Secret**: Yes
**Author-Nickname**: Banana Split

Each metadata macro is 'labelled', allowing you to:

- insert multiple Metadata macros on a single page or blog post, each with a different label
- use the Metadata Summary macro to generate a summary based on Metadata macros tagged with a specific label.

Metadata macro 'label's are completely unrelated to page labels. A Metadata macro's label is only used by the Metadata Summary macro for the purpose of generating its summary.
As far as the Metadata Summary macro is concerned, each field only possesses a single value. Hence, if you added multiple values to a field (for example, by separating each value with a comma), the Metadata Summary macro treats this as a single value and presents it as such.

On this page:
- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
- Parameters

Usage with the Macro Browser

To insert the metadata macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'insert' to put the macro into the page.

Once you've found the metadata macro, click 'insert' to add it to your page.

Usage with the Wiki Markup Editor

```
{details:label=test}
Is-Secret: Yes
Author-Nickname: Banana Split
{details}
```

Each metadata item is added on a separate line. Separate each field and value with a colon (:) followed by a space. For example: `colour: Red`.

In the example above,
- `test` is the label of this metadata macro, which can be identified uniquely on a page in a metadata summary
- `Is-Secret` is a field of value `Yes`
- `Author-Nickname` is another field with a value of `Banana Split`.

Parameters

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in **Bold** text, while their equivalents in wiki markup are indicated in *(bracketed)* text. If the latter is not shown, then in wiki markup, the parameter's name should be omitted and only its value should be added immediately after the colon symbol (:).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required in Wiki Markup?</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Metadata Label (label)</td>
<td>yes</td>
<td>none</td>
<td>Used by the Metadata Summary macro to generate a summary based on all Metadata macros tagged with this label throughout the current space.</td>
</tr>
</tbody>
</table>

**RELATED TOPICS**

Working with Macros

Take me back to the Confluence User Guide.

**Metadata Summary Macro**

The **Metadata Summary macro** presents a tabulated summary of selected metadata, which has been embedded using the **Metadata Macro** on any page or blog post in the current Confluence space.

The left-most column of the metadata summary shows the name of each page or blog post within current space that contains the selected metadata. Each page or blog post is presented on a single row and is hyperlinked to its appropriate destination page.
Each subsequent column represents a unique field within the selected metadata. The value associated with each metadata field on a page or blog post is presented in the appropriate cell of the metadata summary table. For example, the following Metadata Summary macro shows all Metadata macros tagged with the 'test' label in the current space.

<table>
<thead>
<tr>
<th>Metadata Macro</th>
<th>Is-Secret</th>
<th>Author-Nickname</th>
<th>Author-Firstname</th>
</tr>
</thead>
<tbody>
<tr>
<td>Metadata Macro</td>
<td>Yes</td>
<td>Banana Split</td>
<td></td>
</tr>
<tr>
<td>Metadata Summary Macro</td>
<td>Strawberry Sundae</td>
<td>Fred</td>
<td></td>
</tr>
</tbody>
</table>

Metadata macro 'label's are completely unrelated to page labels. A Metadata macro's label is only used by the Metadata Summary macro for the purpose of generating its summary.

On this page:
- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
- Parameters
- Another Metadata Macro Example

Usage with the Macro Browser

To insert the metadata summary macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'insert' to put the macro into the page.

Once you've found the metadata summary macro, click 'insert' to add it to your page.

Usage with the Wiki Markup Editor

```markuptext
{details:summary:label=test}
```

This shows a metadata summary based on all Metadata macros in pages or blog posts of the current space, which have been labelled with 'test'.

Parameters

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in Bold text, while their equivalents in wiki markup are indicated in (bracketed) text. If the latter is not shown, then in wiki markup, the parameter's name should be omitted and only its value should be added immediately after the colon symbol (:).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required in Wiki Markup?</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Metadata Label</td>
<td>yes</td>
<td>none</td>
<td></td>
</tr>
<tr>
<td>(label)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Restricts the Metadata Summary macro to summarise the contents of Metadata macros throughout the current space, which have been tagged with this label only.

Another Metadata Macro Example

The following Metadata macro example generates the second line in the Metadata Summary macro (above).

**Author-Nickname**: Strawberry Sundae
**Author-Firstname**: Fred

**RELATED TOPICS**

Working with Macros
Network Macro

The **Network** macro displays a list of Network interactions between users in your Confluence site, on your Confluence page or blog.

The Network macro allows you to specify the user whose network interactions you wish to show. These interactions include the users that the specified user is following or users who are following the specified user. The Network macro depicts each listed user by their profile picture. It also provides a choice of two themes and the ability to limit the number of users in the list.

**Screenshot: Network Macro**

### Following

You are following 10 users

<table>
<thead>
<tr>
<th>User name</th>
<th>Follow</th>

<tbody>
<tr>
<td>{noformat:nopanel=true} I do not want this text formatted!</td>
<td>I do not want this text formatted!</td>
</tr>
<tr>
<td>{noformat}</td>
<td></td>
</tr>
</tbody>
</table>

Format the panel

All of the optional parameters for the Panel macro are also valid for the Noformat macro.

RELATED TOPICS

Working with Macros

Take me back to the Confluence User Guide.

Nolink and nl Macros

The Nolink (or nl) macro allows you to enter a web address or URL, without the browser automatically hyperlinking the URL.

On this page:

- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
- Parameters

Usage with the Macro Browser

To insert the Nolink macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'insert' to put the macro into the page.

Once you've found the Nolink macro and have added the required parameter values, click 'insert' to add it to your page.

Usage with the Wiki Markup Editor

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>{nolink:<a href="http://www.atlassian.com%7D">http://www.atlassian.com}</a></td>
<td><a href="http://www.atlassian.com">http://www.atlassian.com</a></td>
</tr>
<tr>
<td>{nl:<a href="http://www.atlassian.com%7D">http://www.atlassian.com}</a></td>
<td><a href="http://www.atlassian.com">http://www.atlassian.com</a></td>
</tr>
</tbody>
</table>

Parameters

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.
Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in **Bold** text, while their equivalents in wiki markup are indicated in *bracketed* text. If the latter is not shown, then in wiki markup, the parameter's name should be omitted and only its value should be added immediately after the colon symbol (:).

<table>
<thead>
<tr>

**Page Index Macro**

The **Page Index macro** creates a hyperlinked alphabetical index of all pages within the current space.

The top section of the Index contains a cell for letter of the alphabet, including separate cells for numbers and symbols. Each of these cells indicates the number of pages in which the first letter of the title matched the corresponding letter, number or symbol in the cell.

The lower section is effectively an extended version of the top section. However, each cell shows the page name followed by the first few sentences of content on that page.

Each letter, number or symbol in the top section is hyperlinked and leads to its corresponding cell in the lower section. Additionally, each page title in the lower section is hyperlinked and leads to its corresponding page in the space.

**Screenshot: Index Macro segment**

Working with Macros

Take me back to the Confluence User Guide.

Pagetree Macro

The Pagetree macro displays a dynamic, hierarchical list of pages starting from a specified parent (root) page. You can embed the page tree into your Confluence page, where it can act as a table of contents or a list of related topics.

When viewing the page tree, your reader can click a link to open the relevant page. The page's current position is highlighted in the page tree.

Below we tell you how to add the Pagetree macro to your page.

Creating a navigation panel for your space

A popular usage of the Pagetree macro is to create a navigation panel showing a table of contents for your space. Read the instructions on Adding a Navigation Sidebar.
Usage with the Macro Browser

To insert the Pagetree macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'Insert' to put the macro into the page.

Once you've found the Pagetree macro and have added the required parameter values, click 'Insert' to add it to your page.

Usage with the Wiki Markup Editor

Include the following markup in your page:

```
{pagetree}
```

There are more examples below.

Macro Parameters

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in **Bold** text, while their equivalents in wiki markup are indicated in (bracketed) text. If the latter is not shown, then in wiki markup, the parameter’s name should be omitted and only its value should be added immediately after the colon symbol (:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required?</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Include Excerpts in Page Tree (excerpt)</td>
<td>no</td>
<td>false</td>
<td>Set this value to 'true' if you want the page tree to show excerpts from each page. The excerpts must be defined on each page by the Excerpt macro.</td>
</tr>
<tr>
<td>Show Expand/Collapse Links (expandCollapseAll)</td>
<td>no</td>
<td>false</td>
<td>Set this value to 'true' if you want to display the 'expand all' and 'collapse all' links at the top of your page tree. Your readers can click these links to open or close all branches of the tree at once.</td>
</tr>
<tr>
<td>Reverse Order (reverse)</td>
<td>no</td>
<td>false</td>
<td>Use this parameter in combination with the sort parameter described below. Set this value to 'true' if you want the pages displayed in descending order rather than ascending order.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Default Value</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
<td></td>

<tr>
<td><strong>Root Page</strong></td>
<td>no</td>
<td>The home page of the space</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Specify the parent page for the page tree. The tree will include all children of the given page, plus their children and grand-children etc. The tree will not include the root page itself. Specify the page title or a special value as follows:</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Your page title — Page tree shows all pages under the specified page.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• @home — Page tree shows all pages under the home page of the space (default).</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• @self — Page tree shows all pages under the current page.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• @parent — Page tree shows all pages under the parent of the current page, including the current page.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• @none — Page tree shows all pages in the space, including orphaned pages and the home page.</td>
<td></td>
</tr>
<tr>
<td><strong>Include Search Box above Page Tree</strong></td>
<td>no false</td>
<td>Set this value to 'true' if you want to include a search box above the page tree. The search box allows your readers to enter a search term, and then searches within the page tree for the specified value.</td>
<td></td>
</tr>
<tr>
<td><strong>Sort Pages By</strong></td>
<td>no position</td>
<td>Specify the order to display the pages in the tree. This sort order is for display purposes only. It does not permanently re-arrange the page order. The value may be one of the following:</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 'bitwise' — Display the pages using standard alphabetical sorting, such as: title1, title10, title2.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 'creation' — Display the pages in order of date created.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 'modified' — Display the pages in order of date last modified.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 'natural' — Display the pages in 'natural' alphabetical order, such as: title1, title2, title10.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 'position' — Display the pages using the default Confluence sorting rules. If your pages have been ordered manually, this sort will respect the defined order. Otherwise the pages will be displayed in the 'natural' alphabetical order, such as: title1, title2, title10.</td>
<td></td>
</tr>
<tr>
<td><strong>Start Depth</strong></td>
<td>no 1</td>
<td>Enter any number greater than 0, indicating how many levels of children the tree should show when it opens for the first time.</td>
<td></td>
</tr>
</tbody>
</table>

**Examples**

**All Parameters**

Here’s an example using all the parameters:

```text
{pagetree:root=Page Name|sort=natural|excerpt=true|reverse=false|startDepth=3|expandCollapseAll=true|searchBox=true}
```

**Specifying the Parent Page by Name**

Use the following code to specify a page name for the parent or root of the tree. The tree will include all children and grand-children of the specified root. The tree will not include the specified root page itself.

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>[pagetree:root=Page Macro]</td>
<td></td>
</tr>
</tbody>
</table>

The above example is a 'live' example. It uses the child pages of this page to form the page tree.

**Showing All Pages in the Space**

Use the following code to make the page tree show all pages in the space, including orphaned pages and the home page.

```text
{pagetree:root=@none}
```

**Setting the Current Page as the Parent Page**
<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>{pagetree:root= @self}</td>
<td>{pagetree:root= @self}</td>
</tr>
</tbody>
</table>

The above example is a 'live' example. It uses the child pages of this page to form the page tree.

**Showing Excerpts from Each Page**

Use the following code if you want your page tree to include excerpts from each page. The excerpts must be defined on each page by the Excerpt macro.

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>{pagetree:root= @self</td>
<td>excerpt= true}</td>
</tr>
</tbody>
</table>

The above example is a 'live' example. It uses the child pages of this page to form the page tree.

**Allowing your Readers to Expand or Collapse All Branches**

Use the following code if you want to show the 'expand all' and 'collapse all' links at the top of your page tree.

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>{pagetree:root= @self</td>
<td>expandCollapseAll= true}</td>
</tr>
</tbody>
</table>

The above example is a 'live' example. It uses the child pages of this page to form the page tree.

**Including a Search Box**

Use the following code if you want to include a search box at the top of your page tree.

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>{pagetree:root= @self</td>
<td>searchBox= true}</td>
</tr>
</tbody>
</table>

The above example is a 'live' example. It uses the child pages of this page to form the page tree.

**Sorting the Pages in Reverse Natural Order**

Use the following code if you want to show the pages in reverse natural order.

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>{pagetree:root= @self}</td>
<td>{pagetree:root= @self}</td>
</tr>
</tbody>
</table>

The above example is a 'live' example. It uses the child pages of this page to form the page tree.
The above example is a ‘live’ example. It uses the child pages of this page to form the page tree.

### Sample Page Tree

This page is a sample, used to demonstrate the Pagetree macro.

For more information, take a look at the main page on the Pagetree Macro.

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>`{pagetree:root=@parent</td>
<td>expandCollapseAll=false}`</td>
</tr>
</tbody>
</table>

### Another Sample Page Tree

We're using this page to demonstrate the Pagetree macro.

For more information, take a look at the main page on the Pagetree Macro.

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>`{pagetree:root=@parent</td>
<td>expandCollapseAll=true}`</td>
</tr>
</tbody>
</table>

### Sample Page Tree 2

This is another sample page, used to demonstrate the Pagetree macro.

For more information, take a look at the main page on the Pagetree Macro.

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>`{pagetree:root=@parent</td>
<td>expandCollapseAll=true}`</td>
</tr>
</tbody>
</table>

### Pagetree Search Macro

The **Pagetree Search macro** allows you to add a search box to your Confluence page. When a viewer enters a search term, Confluence will search a hierarchy of pages starting from a specified parent (root) page and return the search results on a new screen.

Below we tell you how to add the Pagetree Search macro to your page.

You may be interested in the Pagetree macro
You can also add a search box as part of a dynamic page tree, which looks like a table of contents. Read the instructions on the Pagetree Macro.

On this page:
Usage with the Macro Browser

To insert the Pagetree Search macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'insert' to put the macro into the page.

Once you've found the Pagetree Search macro and have added the required parameter values, click 'insert' to add it to your page.

Usage with the Wiki Markup Editor

Include the following markup in your page:

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>{pagetreesearch}</td>
<td></td>
</tr>
</tbody>
</table>

Macro Parameters

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in **Bold** text, while their equivalents in wiki markup are indicated in *(bracketed)* text. If the latter is not shown, then in wiki markup, the parameter’s name should be omitted and only its value should be added immediately after the colon symbol (:).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required?</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name of Root Page</td>
<td>no</td>
<td>none</td>
<td>The name of the root page whose hierarchy of pages will be searched by this macro. If this not specified, the root page is the current page.</td>
</tr>
</tbody>
</table>

Panel Macro

The **Panel Macro** allows you to display a block of text within a customisable panel.

Once the Panel macro has been inserted on a page, you can only edit its parameters in Wiki Markup mode.

On this page:

- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
- Parameters

Usage with the Macro Browser

To insert the Panel macro into a page using the Macro Browser,
1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'Insert' to put the macro into the page.

Once you’ve found the Panel macro and have added the required parameter values, click ‘Insert’ to add it to your page.

Usage with the Wiki Markup Editor

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>{panel}</td>
<td>A simple panel</td>
</tr>
<tr>
<td>{panel}</td>
<td>A simple panel</td>
</tr>
<tr>
<td>{panel:title=My Title</td>
<td>borderStyle=dashed</td>
</tr>
</tbody>
</table>

Handy Hint: You can use panels within columns.

Quote Macro

The **Quote** Macro allows you to present a section of text as a quote or citation, allowing you to add further information in the form of a response. This is similar to the way people sometimes reply to email messages, by adding their responses immediately after citations of the originator's text.

For example, when adding a comment to a Confluence page or blog and you wish to cite some content on it, you can do so with this macro as follows:

```
| This is similar to the way people sometimes reply to email messages, by adding their responses immediately after citations of the originator’s text. |
| I often reply to other's email messages in this manner. |
```

On this page:
- Usage with the Macro Browser
- Usage in Wiki Markup
- Parameters

**Usage with the Macro Browser**

To insert the quote macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'Insert' to put the macro into the page.

Once you've found the quote macro, click 'insert' to add it to your page.

**Usage in Wiki Markup**

Recently Updated Dashboard Macro

The Recently Updated Dashboard macro displays a list of the most recently changed content within Confluence. It is similar to the Recently Updated macro but is intended for use on the Confluence dashboard.

On this page:

- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
- Parameters
- Examples
  - 1. Include all spaces and limit the display width to 50%
  - 2. Specify the spaces for which you want to view recently updated content
  - 3. Specify the width of the macro display
  - 4. Filter content using labels
  - 5. Display profile pictures
  - 6. Display recent comments, including profile pictures and text

Usage with the Macro Browser

To insert the recently updated dashboard macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'insert' to put the macro into the page.

Once you've found the recently updated dashboard macro and have added the required parameter values, click 'insert' to add it to your page.

Parameters

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in Bold text, while their equivalents in wiki markup are indicated in (bracketed) text. If the latter is not shown, then in wiki markup, the parameter's name should be omitted and only its value should be added immediately after the colon symbol (:).
### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required?</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Label(s)</strong> (labels)</td>
<td>no</td>
<td>none</td>
<td>Filter content by label. The macro will display only the pages etc which are tagged with the label(s) you specify here. You can specify one or more labels, separated by commas. If there are no pages matching any of the specified labels, then Confluence will ignore the labels and will list all recently updated pages, as well as showing a message, “These labels don’t exist and were ignored: xxx”. This unexpected behaviour is noted in issue CONF-10167.</td>
</tr>
<tr>
<td><strong>Show User Profile Pictures</strong> (showProfilePic)</td>
<td>no</td>
<td>false</td>
<td>Specify showProfilePic=true to display the profile pictures of the users who updated the content.</td>
</tr>
<tr>
<td><strong>Space(s)</strong> (spaces)</td>
<td>no</td>
<td>The space which contains the page on which the macro is coded</td>
<td>Filter content by space. The macro will display only the pages etc which belong to the space(s) you specify here. You can specify one or more space keys, separated by commas. &quot;*&quot; means all spaces.</td>
</tr>
<tr>
<td><strong>Include these Content Types Only</strong> (types)</td>
<td>no</td>
<td>all types</td>
<td>Filter content by type. You can specify one or more types, separated by commas. Available types are: page, blogpost or news, spacedesc, attachment, comment, mail, userinfo.</td>
</tr>
<tr>
<td><strong>Width of Table</strong> (width)</td>
<td>no</td>
<td>100%</td>
<td>Specify the width of the macro display, as a percentage of the window width.</td>
</tr>
</tbody>
</table>

### Examples

1. Include all spaces and limit the display width to 50%

The code below will show all the pages from all the spaces that have been recently updated.

```
{recently-updated-dashboard:spaces=|width=50%}
```

2. Specify the spaces for which you want to view recently updated content

```
{recently-updated-dashboard:spaces=Name1,Name2|width=50%}
```

3. Specify the width of the macro display

```
{recently-updated-dashboard:width=50%}
```

4. Filter content using labels

```
{recently-updated-dashboard:spaces=sales,marketing|labels=timesheets,summaries}
```

5. Display profile pictures

The code below will display the profile picture of the user who most recently updated the content.

```
{recently-updated-dashboard:showProfilePic=true}
```

6. Display recent comments, including profile pictures and text

The code below will display recent comments in the current space, showing the profile picture of the users who made the comments, plus the first line or two of the comment text. This is the only way to ensure that the text of the comments is displayed, using this macro.

```
{recently-updated-dashboard:types=comment|showProfilePic=true}
```
Customising the wording
If you would like to change the wording displayed by the 'Recently Updated' macro, please refer to the document on modifying the Confluence interface text.

Working with Macros

Take me back to the Confluence User Guide.

Recently Updated Macro

The **Recently Updated** macro displays a list of the most recently changed content within Confluence.

The **Recently Updated Dashboard** macro is similar to this macro, but is intended for display on the Confluence dashboard.

On this page:

- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
- Working Example of Usage
- Parameters
- Examples
  - 1. Include content from all spaces
  - 2. Include content from specific spaces
  - 3. Specify the width of the display
  - 4. Filter content using labels
  - 5. Sort the results
  - 6. Filter by content type
  - 7. Change the number of results in the list
  - 8. Display profile pictures
  - 9. Display recent comments, including profile pictures and text

Usage with the Macro Browser

**To insert the recently updated macro into a page using the Macro Browser,**

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon [ ] on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'insert' to put the macro into the page.

Once you've found the recently updated macro and have added the required parameter values, click 'insert' to add it to your page.

Usage with the Wiki Markup Editor

```
{recently-updated}
```

Working Example of Usage

Below is a working example of the 'Recently Updated' macro which by default, lists 15 results.

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
</table>
Parameters

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in Bold text, while their equivalents in wiki markup are indicated in (bracketed) text. If the latter is not shown, then in wiki markup, the parameter’s name should be omitted and only its value should be added immediately after the colon symbol (:).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required?</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Author(s) by username (author)</td>
<td>no</td>
<td>None specified i.e. display all content</td>
<td>Filter the results by author. The macro will display only the pages etc which were last modified by the author(s) you specify here. You can specify one or more authors, separated by a comma or a space.</td>
</tr>
<tr>
<td>Label(s) (label) or (labels)</td>
<td>no</td>
<td>None specified i.e. display all content</td>
<td>Filter the results by label. The macro will display only the pages etc which are tagged with the label(s) you specify here. You can specify one or more label values, separated by a comma or a space.</td>
</tr>
<tr>
<td>Maximum Number of Results (max) or (maxResults)</td>
<td>no</td>
<td>15</td>
<td>Specify the maximum number of results to be displayed. Note that the results are sorted first, and then the maximum parameter is applied. If this parameter is omitted, then a maximum of 15 results are displayed. The theoretical maximum value that this parameter can accept is 2 to the power of 31, minus 1 (or 2147483647).</td>
</tr>
</tbody>
</table>

- To exclude content which matches a given label, put a minus sign (-) immediately in front of that label value. For example: If you specify a label value of 'badpage' you will get only content which is not labelled with 'badpage'.
- To indicate that the results must match a given label value, put a plus sign (+) immediately in front of that label value. For example: If you specify a label value of superpage, goodpage you will get only content which has at least two labels, being 'superpage' and 'goodpage'.

If there are no pages matching any of the specified labels, then Confluence will ignore the labels and will list all recently updated pages, as well as showing a message, "These labels don’t exist and were ignored: xxx". This unexpected behaviour is noted in issue CONF-10167.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Reverse Sort</strong> (reverse)</td>
<td>no</td>
<td>Use this parameter in conjunction with the <code>sort</code> parameter described below. Set <code>reverse=true</code> to change the sort from ascending to descending order. This parameter is ignored if the <code>sort</code> parameter is not specified.</td>
</tr>
<tr>
<td><strong>Show User Profile Pictures</strong> (showProfilePic)</td>
<td>no</td>
<td>Specify <code>showProfilePic=true</code> to display the profile pictures of the users who updated the content.</td>
</tr>
</tbody>
</table>
| **Sort By** (sort)                            | no      | Specify how the results should be sorted. To change the sort order from ascending to descending, use the `reverse` parameter described above. If this parameter is not specified, the sort order defaults to descending order based on the last modification date. Values:  
  - `creation` — Sort by the date on which the content was added.  
  - `title` — Sort alphabetically by title.  
  - `modified` — Sort by the date on which the content was last updated. |
| **Space(s)** (space) or (spaces)              | no      | This parameter allows you to filter content by space. The macro will display only the pages etc which belong to the space(s) you specify here. You can specify one or more space keys, separated by a comma or a space.  
  - To exclude content in a specific space, put a minus sign (-) immediately in front of that space key. For example: If you specify a space key of `-BADSPACE` you will get only content which is not in the BADSPACE.  
  - To indicate that the results must come from a specific space, put a plus sign (+) immediately in front of that space key. For example: If you specify a space key of `+GOODSPACE` you will get only content in GOODSPACE. (Note that this is not particularly useful, because each content item belongs to one space only. If you put a plus sign next to one space key and list other space keys too, the other space keys will be ignored.) Special values:  
    - `@self` — The current space.  
    - `@personal` — All personal spaces.  
    - `@global` — All global spaces.  
    - `@favorite` — The spaces you have marked as favourite.  
    - `@favourite` — The same as `@favorite` above.  
    - `@all` — All spaces in your Confluence site.  
    - `*` — The same as `@all` above.  
  When specifying a personal space, remember to use the tilde (~) sign in front of the username, such as `~jbloggs ~jbloggs@example.com`. |
| **Include these Content Types Only** (type) or (types) | no      | This parameter allows you to filter content by content type. The macro will display only the content of the type you specify here. You can specify one or more types, separated by a comma or a space.  
  To exclude content of a given content type, put a minus sign (-) immediately in front of that content type. For example: if you specify a content type of `-blogpost` you will get pages and all other content except for blog posts. Available values:  
    - `page` — Pages.  
    - `blogpost` or `news` — Blog posts, also known as news items.  
    - `comment` — Comments on pages and blog posts.  
    - `mail` — Email messages.  
    - `attachment` — Attachments.  
    - `status` — Status updates made by other users. |
| **Width of Table** (width)                    | no      | Specify the width of the macro display, as a percentage of the window width. |
Confluence 3.0 Documentation

<table>
<thead>
<tr>
<th>theme (theme)</th>
<th>no</th>
<th>'concise' with the heading 'Recently Updated'</th>
<th>Choose the appearance of this macro:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td>• concise — the default list, showing the names of pages which were updated or commented on, the users who made the page modifications and time when the modifications occurred.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• social — lists recent modifications in reverse chronological order, but groups them by user into short time segments. A 'sub' list appears within each user's time segment, showing the names of pages which they updated or commented on and time when these modifications occurred.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• sidebar — lists recent updates in reverse chronological order, showing the names of pages which were updated or commented on and time when the page modifications occurred. This theme does not show authorship.</td>
</tr>
</tbody>
</table>

Examples

1. Include content from all spaces

The code below will show all the pages from all the spaces that have been recently updated:

```{recently-updated:space=all}```

2. Include content from specific spaces

Use the code below to specify the spaces for which you want to view recently updated content:

```{recently-updated:space=SPACEKEY1,SPACEKEY2}```

3. Specify the width of the display

Use the code below to limit the width of the display to 50% of the window:

```{recently-updated:width=50%}```

4. Filter content using labels

The code below will include recently updated content labelled with 'timesheets' or 'summaries', from the 'sales' and 'marketing' spaces, provided that the content is not labelled with 'obsolete':

```{recently-updated:space=sales,marketing|label=timesheets,summaries,-obsolete}```

5. Sort the results

Use the code below to sort the list of items by date last modified, with the most recent at the top:

```{recently-updated:sort=modified|reverse=true}```

6. Filter by content type

Use the code below to show pages only (not news items, comments or any other content type) and sort the list of items by date last modified, with the most recent at the top:

```{recently-updated:sort=modified|reverse=true|type=page}```

7. Change the number of results in the list

The code below changes the number of results listed (from the default value of 15) to 8:

```{recently-updated:maxResults=8}```

8. Display profile pictures

The code below will display the profile picture of the user who most recently updated the content.
9. Display recent comments, including profile pictures and text

The code below will display recent comments in the current space, showing the profile picture of the users who made the comments, plus the first line or two of the comment text.

This is the only way to ensure that the text of the comments is displayed, using this macro.

{recently-updated-dashboard:showProfilePic=true|types=comment}

Customising the wording

If you would like to change the wording displayed by the 'Recently Updated' macro, please refer to the document on modifying the Confluence interface text.

Working with Macros

Take me back to the Confluence User Guide.

RSS Feed Macro

The RSS feed macro embeds an RSS feed on a page. It can display the contents of external feeds, or of internal feeds generated by Confluence. To display blog posts or to list recently updated pages in a space, use the Feed Builder to create an internal feed, then render it using this macro.

CAUTION: Including unknown HTML inside a webpage is dangerous.

HTML inside an RSS feed can contain active scripting components. This means that it would be possible for a malicious attacker to present a user of your site with script that their web browser would believe came from you. Such code could be used, for example, to steal a user's authentication cookie and give the attacker their Confluence login password.

The RSS macro will only be available if it has been enabled by your Confluence administrator. Also, your Confluence Administrator can define a whitelist of trusted URLs. You will see an error message on the Confluence page, if the included URL is not in the whitelist.

On this page:

- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
- Parameters
- Examples
  - 1. Limit the number of entries displayed
  - 2. Show only the RSS feed titles
  - 3. Hide the feeds titlebar
- Working Example
- How Up to Date is the Feed?
- What Happens to a Page Containing a Disallowed URL?
- Authentication
- Accessing Internal HTTPS Feeds

Usage with the Macro Browser

To insert the RSS feed macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'insert' to put the macro into the page.

Once you've found the RSS feed macro and have added the required parameter values, click 'insert' to add it to your page.
Usage with the Wiki Markup Editor

Use the Wiki Markup editor to edit the page and insert the RSS macro. Replace the 'http://www.example.com/rss/' URL with your own feed link in this example:

```
{rss:url=http://www.example.com/rss/}
```

Parameters

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in **Bold** text, while their equivalents in wiki markup are indicated in (bracketed) text. If the latter is not shown, then in wiki markup, the parameter’s name should be omitted and only its value should be added immediately after the colon symbol (:).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required?</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RSS Feed URL (url)</td>
<td>yes</td>
<td>none</td>
<td>The URL of the RSS feed link you want to show.</td>
</tr>
<tr>
<td>Maximum Number of Entries (max)</td>
<td>no</td>
<td>15</td>
<td>Limit the number of entries displayed.</td>
</tr>
<tr>
<td>Show Item Titles Only (showTitlesOnly)</td>
<td>no</td>
<td>false</td>
<td>Show only the titles of the news items, not the content.</td>
</tr>
<tr>
<td>Show Name/Title of RSS Feed (titleBar)</td>
<td>no</td>
<td>true</td>
<td>Hide the feeds title bar.</td>
</tr>
</tbody>
</table>

Examples

1. Limit the number of entries displayed

```
{rss:url=http://host.com/rss.xml|max=5}
```

2. Show only the RSS feed titles

```
{rss:url=http://host.com/rss.xml|showTitlesOnly=true}
```

3. Hide the feeds titlebar

```
{rss:url=http://host.com/rss.xml|titleBar=false}
```

Working Example

What you need to type:

```
{rss:url=http://www.abc.net.au/news/syndicate/breakingrss.xml|max=5|showTitlesOnly=true}
```

What you will get:

**ABC News: Breaking Stories [RSS]**
(Latest ABC News)
- Nanoparticles damage DNA remotely: study
- Stolen Generations linked to increased violence
- Texas military base gunman 'harassed'
- Indonesia extends Oceanic Viking’s stay
- HOG heaven revs up

How Up To Date is the Feed?
By default, the RSS Feed macro caches the feed results for 60 minutes before fetching the data again.

If you wish to change the default caching, use the `{cache}` macro to define how often the RSS Feed macro fetches the feed updates. You may want to set the cache to a longer period, so that your page loads faster. Or you may want to retrieve feed results more often, if you need to see the updates sooner. You will need to install the Cache plugin onto your Confluence site.

To enable caching:

1. Using the Confluence Repository, install the 'Scripting Plugin' and the 'Utilities Plugin'.
2. For each RSS macro that you wish to cache, surround your RSS macro with a Cache macro. For example, to cache feeds for 30 minutes:

   `{cache:refresh=30m}
   {rss:url=http://rss.news.yahoo.com/rss/stocks[max=5]}
   {cache}`

   The Cache plugin page provides more information on customising the cache behaviour.

What Happens to a Page Containing a Disallowed URL?

Your Confluence Administrator can set up a whitelist of allowed URLs. If this is the case, you may see an error on the pages which contain the RSS macro.

A user can add the RSS macro or the HTML-include macro to a Confluence page. The macro code includes a URL from which the content is drawn. When the page is displayed, Confluence will check the URL against the whitelist. If the URL is not allowed, Confluence will display an error message on the page.

The error message says that Confluence "could not access the content at the URL because it is not from an allowed source" and displays the offending URL. If the person viewing the page is a Confluence Administrator, they will also see a link to the Administration page where they can configure the URL whitelist.

Here is an example of the error message, including the link shown only to Confluence Administrators:

```
Could not access the content at the URL because it is not from an allowed source.
http://feathers.wordpress.com
Configure whitelist >>
```

Here is an example of the error message, but without the link.

```
Could not access the content at the URL because it is not from an allowed source.
http://feathers.wordpress.com
You may contact your site administrator and request that this URL be added to the list of allowed sources.
```

Authentication

Adding Login Information for Confluence Feeds

You can add your Confluence username and password to the feed URL, so that the RSS Feed Macro can log in to Confluence.

⚠️ Please note that if you do this, someone with access to your RSS newsreader configuration can read your password.

Private Feeds from External Sites

RSS feeds which require authentication cannot be accessed using the RSS Macro.

Accessing Internal HTTPS Feeds

This applies only to Confluence instances which have enabled HTTPS for all content. If your site is fully HTTPS, the RSS macro cannot access internal feeds. To enable the RSS macro to access internal feeds without affecting your HTTPS setup, enable local-only HTTP access:

1. Shut down Confluence.
2. Use the SSL guide to re-enable HTTP access to Confluence. This means that Confluence will be accessible via both HTTP and HTTPS.
3. Insert a firewall rule to redirect all HTTP requests not from the Confluence server to the equivalent HTTPS URL. This ensures that users will only be able to access Confluence via HTTPS, as intended. If you have still left HTTP access for attachments enabled (to
avoid the IE download bug) you must selectively enable those URLs as well.
4. Modify your Confluence RSS macro feed link to use the HTTP URL, and restart Confluence.

**RELATED TOPICS**

- Tracking Updates Overview
- Working with Macros
- Configuring a URL Whitelist

Return to the Confluence User Guide.

**Search Macro**

The Search macro searches your Confluence site based on search terms specified in the macro code, and displays the results on the wiki page.

**On this page:**

- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
  - Found 9 search result(s) for **my_query**.
  - Parameters
    - 1. Setting a limit to the number of search results displayed
    - 2. Specifying the key of the space you want to search
    - 3. Specifying the content type
    - 4. Specifying a time period in which the content was last modified
    - 5. Limiting the search results to content created or modified by a specific user

**Usage with the Macro Browser**

**To insert the search macro into a page using the Macro Browser,**

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'insert' to put the macro into the page.

Once you've found the search macro and have added the required parameter values, click 'insert' to add it to your page.

**Usage with the Wiki Markup Editor**

In the example below, we assume that you want to search for all pages and other content types which contain the term 'my_query'.

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
</table>

Found 9 search result(s) for **my_query**.
### Parameters

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in **Bold** text, while their equivalents in wiki markup are indicated in *(bracketed)* text. If the latter is not shown, then in wiki markup, the parameter's name should be omitted and only its value should be added immediately after the colon symbol (:).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required?</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Search Terms</strong> <em>(query)</em></td>
<td>yes</td>
<td>none</td>
<td>The search terms which this macro will use to generate its results. You can refine your search query by using operators such as 'AND' and 'OR'. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- In the macro browser <strong>Search Terms</strong> entry box: <em>my_query1 AND my_query2</em></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- In wiki markup editor: <code>{search:query=my_query1 AND my_query2}</code></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>For more information, take a look at the documentation on the Confluence search syntax.</td>
</tr>
<tr>
<td><strong>Maximum Number of Results</strong> (maxLimit)</td>
<td>no</td>
<td>no limit</td>
<td>Set a limit to the number of search results displayed.</td>
</tr>
<tr>
<td><strong>Restrict to this Space Key</strong> (spacekey)</td>
<td>no</td>
<td>all</td>
<td>Specify the key of the space you want to search in. Note that this is case sensitive.</td>
</tr>
<tr>
<td><strong>Content Type</strong> (type)</td>
<td>no</td>
<td>all</td>
<td>Specify the content type. The content types are: page, comment, blogpost, attachment, userinfo (the content of user profiles only), spacedesc (the content of space descriptions only) and mail.</td>
</tr>
</tbody>
</table>
| **Last Modified** (lastModified) | no | all | Specify a period of time in weeks, days, hours and/or minutes, to see the content modified within that time frame. For example:
- 2h 35m
- 3d 30m
These are the values you can use:
- w = weeks
- d = days
- h = hours
- m = minutes
If no time category is specified, Confluence assumes minutes. If you specify more than one time period (e.g. weeks and days), the periods must be separated by a space and they can come in any order. The time categories are not case sensitive e.g. ‘4d’ is the same as ‘4D’. |
| **Restrict to this Username** (contributor) | no | all | Specify the username of a Confluence user, to show only content created or updated by that user. |

1. **Setting a limit to the number of search results displayed**
Display a limit to the number of search results displayed.

```
{search:query=my_query|maxLimit=20}
```

2. **Specifying the key of the space you want to search**
Global space: Search within the Doctemp space only.

```
{search:query=my_query|spacekey=Doctemp}
```

Personal space: Search within jsmith’s space only.

```
{search:query=my_query|spacekey=jsmith}
```

3. **Specifying the content type**
Search within comments only.

```
{search:query=my_query|type=comment}
```

4. **Specifying a time period in which the content was last modified**
Search for content modified in the last one week and two days.

```
{search:query=my_query|lastModified=1w 2d}
```

5. **Limiting the search results to content created or modified by a specific user**
Search within content created or updated by jsmith only.

```
{search:query=my_query|contributor=jsmith}
```
Permissions
When a user views the page containing the Search macro, the search results will show only pages and other content types for which the user has 'View' permission.

Working with Macros

Take me back to the Confluence User Guide.

Section Macro
The section macro allows you to define a section of a page in which you can insert one or more columns across the page.

To add sections and columns to a page:
1. Insert a pair of section macro elements to define the section of page that will contain your set of columns.
2. Within this pair of section macro elements, insert a pair of column macro elements. Repeat step 2 for each column you want to insert across this section of the page.

On this page:
- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
- Parameters

Usage with the Macro Browser
To insert the section macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'Insert' to put the macro into the page.

Once you've found the section macro and have added the required parameter values, click 'Insert' to add it to your page.

Usage with the Wiki Markup Editor

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>{section:border=true}</td>
<td>Column one text goes here</td>
</tr>
<tr>
<td>(column)Column one text goes here (column)</td>
<td>Column two text goes here</td>
</tr>
<tr>
<td>(section)Column two text goes here (column)</td>
<td></td>
</tr>
</tbody>
</table>

Parameters
Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in Bold text, while their equivalents in wiki markup are indicated in (bracketed) text. If the latter is not shown, then in wiki markup, the parameter's name should be omitted and only its value should be added immediately after the colon symbol (:\)

<table>
<thead>

Space Details Macro

The Space Details macro renders the space's details in a table within the page.

On this page:
- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
- Parameters

Usage with the Macro Browser

To insert the space details macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'Insert' to put the macro into the page.

Once you've found the space details macro, click 'Insert' to add it to your page.

Usage with the Wiki Markup Editor

<table>
<thead>

</tr>
</tbody>
</table>
Spacegraph Macro

⚠️ The Spacegraph Macro requires the Graphviz Plugin

To use the Spacegraph macro, you will need to install the Graphviz plugin onto your Confluence site. This plugin is not shipped with Confluence by default, and is not officially supported by Atlassian.

- Please read more about supported and unsupported plugins.
- You can find more information about the Graphviz plugin on the plugin documentation page.

The Spacegraph macro displays a chart of all the pages in a space and the connections between them.

For details on composing diagrams, see the GraphViz documentation.

**Spacegraph Macro**

```
{spacegraph}
```

Optional Parameter

Specify the space by including its space key in the macro

```
{spacegraph:doctemp}
```

By default, the graph of the current space is shown.

Spaces List Macro

The Spaces List Macro is used to display a list of spaces from within a page.

By default, Confluence lists the spaces from your current view of spaces on the Dashboard.

For each space listed, there is a link to browse the space, and to add a new page (if the user has permission to create pages).

**On this page:**

Creating a New Page
Working with Macros

Take me back to the Confluence User Guide.

**Table of Contents Macro**

The Table of Contents macro is documented on the CustomWare Atlassian Plugins website.

Due to an outstanding issue in the Table of Contents macro (CONF-10619), the Macro Browser's Refresh function does not render any parameter modifications. Currently, the rendering of parameter value modifications to the Table of Contents macro occurs only after the page is saved.

**Using HTML Heading Markup with the Table of Contents Macro**

The Table of Contents macro cannot handle HTML heading markup on its own. Hence, if you used the HTML and HTML Include macros to render HTML heading markup in a Confluence page, the Table of Contents macro will not create a contents list out of these headings. (For more information on about this issue, please refer to TOC-93.)

However, if you insert an HTML anchor into each HTML heading on your page (based on the following syntax), the Table of Contents macro will incorporate these headings into your contents list.

```
<h2><a name="pagename-headingname">Heading Name</a></h2>
```

The syntax for the anchor name is usually the page name and heading name separated by a hyphen, in which the page and heading names have all spaces removed and are converted to lowercase. If punctuation marks occur within a page or heading name, each mark should usually be converted to its URL escape code in the anchor name.

**Table of Contents Zone Macro**

The Table of Contents Zone macro is documented on the CustomWare Atlassian Plugins website.

Due to an outstanding issue in the Table of Contents Zone macro (CONF-10619), the Macro Browser's Refresh function does not render any parameter modifications. Currently, the rendering of parameter value modifications to the Table of Contents Zone macro occurs only after the page is saved.

**Using HTML Heading Markup with the Table of Contents Zone Macro**

The Table of Contents Zone macro cannot handle HTML heading markup on its own. Hence, if you used the HTML and HTML Include macros to render HTML heading markup in a Confluence page, the Table of Contents Zone macro will not create a contents list out of these headings. (For more information on about this issue, please refer to TOC-93.)

However, if you insert an HTML anchor into each HTML heading on your page (based on the following syntax), the Table of Contents Zone macro will incorporate these headings into your contents list.

```
<h2><a name="pagename-headingname">Heading Name</a></h2>
```

The syntax for the anchor name is usually the page name and heading name separated by a hyphen, in which the page and heading names have all spaces removed and are converted to lowercase. If punctuation marks occur within a page or heading name, each mark should usually be converted to its URL escape code in the anchor name.

**Tasklist Macro**
The Tasklist macro allows you to create and update a list of tasks on the wiki page. Users viewing the page can modify the tasks without putting the page into 'Edit' mode, provided they have the required permissions to modify the page.

Dynamic Tasklist 2 plugin is shipped with Confluence 2.8
The tasklist macro is supplied by the Dynamic Tasklist 2 plugin, which is bundled with Confluence version 2.8 and later. The new tasklist macro replaces the older tasklist and dynamictasklist macros.

On this page:
- Usage with the Macro Browser
- Usage with the Wiki Markup Editor
- Parameters
- Editing the Task List while Viewing a Page
- Sorting the Tasks
- Viewing the Progress on Tasks Completed
- Editing the Wiki Markup for a Task List

Usage with the Macro Browser

To insert the tasklist macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'insert' to put the macro into the page.

Once you've found the tasklist macro, click 'insert' to add it to your page.

Usage with the Wiki Markup Editor

To add a task list using the Wiki Markup Editor, you must first edit the page and then type the macro code:

{tasklist:NAME OF TASK LIST}

Here is an example:

What you need to type | What you will get
---|---
{tasklist:Planning a Holiday}| Planning a Holiday

Parameters

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in **Bold** text, while their equivalents in wiki markup are indicated in *(bracketed)* text. If the latter is not shown, then in wiki markup, the parameter's name should be omitted and only its value should be added immediately after the colon symbol (:).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required?</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Title</td>
<td>no</td>
<td>'Task List'</td>
<td>The name of the task list. This is displayed as the title above the list of tasks. For example: <code>{tasklist:Things to Do}</code></td>
</tr>
<tr>
<td>(width)</td>
<td>no</td>
<td>530px</td>
<td>The width of the task list. For example, in Wiki Markup: `{tasklist:Things to Do</td>
</tr>
</tbody>
</table>
Editing the Task List while Viewing a Page

While viewing a page, you can change the tasks in a task list as follows:

- **Adding a task**: Type the task description in the text box under the list name, and click the 'Add' button.
- **Completing/completing a task**: Click the checkbox next to a task to mark the task as complete. The task name will become a lighter color and the progress bar will be updated. Click the checkbox again to mark the task as uncompleted. You can also click the 'Uncheck all' button to mark all tasks as uncompleted.
- **Editing a task**: Move your mouse to hover your cursor over the task. Click the edit icon (pencil) that appears to the right of the task. The task name will become editable and the edit icon will be replaced with a save icon. Make your change and press the 'Enter' key to save or click the save icon.
- **Deleting a task**: Move your mouse to hover your cursor over the task. Click the delete icon (trash can) that appears to the right of the task.
- **Viewing details of a task**: Click the arrow icon to the left of the task name. The task details will open in an expanded view.
- **Locking a task**: Provided that the `enableLocking` parameter has been set to 'true', you can lock the task to prevent the task from being edited, deleted, or otherwise changed.

Once the task details are visible, you have more options:

- **Changing the priority**: Click the appropriate radio button — 'High', 'Medium' or 'Low'.
- **Assigning the task**: Change the assignee of the task by typing in or searching for a username.

### Screenshot: Task List showing Task Details

**Planning a Holiday**

- Book tickets
- Check passport expiry
- Apply for visa
- Buy suitcases

**Priority:**
- High
- Medium
- Low

**Assigned To:** smaddox

**Created:** Mar 28, 2008

**Sort by:** Custom

### Sorting the Tasks

There are two ways to sort the entries in the task list:

- The 'Sort by' dropdown list.
- Drag and drop.

Using the 'Sort by' dropdown list to sort the tasks:

- Click the 'Sort by' dropdown list and select one of the options:
  - **Custom**: This is the default option.
  - **Priority**: Sort the list in order of the priority you have allocated to each task.
  - **Date Created**: Sort the list in order of the dates upon which the tasks were created.
  - **Completed**: Move all completed tasks to the bottom or top of the list.
  - **Name**: Sort the list in order of the task names.
  - **Assignee**: Sort the list in order of the usernames assigned to the tasks.
- When you have selected a sort order, a new ascending/descending sequence icon appears to the right of the 'Sort by' box. Click the ascending/descending sequence icon to reverse the sort order.

Dragging and dropping a task into a new position:
• Click the ‘drag me’ handle to the right of the task name.
• Holding down the mouse button, drag the task up or down the list. Make sure the task is positioned to the left of the existing tasks. A space will open and you will be able to drop the task into its new position.

**Viewing the Progress on Tasks Completed**

The bar at the top of the task list displays two different colours, indicating the percentage of tasks completed.

_Screenshot: Progress Bar on Task List_

![Screenshot of task list with progress bar]

**Editing the Wiki Markup for a Task List**

The data for the task list is stored in the Confluence page. Most people will find it easier to add or modify tasks while viewing the page. But if you want to edit or even create the task list directly, you can do so by editing the page itself. Here is an example, showing the Wiki Markup for the above task list:

```
{tasklist:Planning a Holiday}
<table>
<thead>
<tr>
<th>Completed</th>
<th>Priority</th>
<th>Locked</th>
<th>CreatedDate</th>
<th>CompletedDate</th>
<th>Assignee</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>F</td>

<th>What you will get</th>
</tr>
</thead>
</table>

### Group: All Users

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required?</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Group(s)</td>
<td>yes</td>
<td>none</td>
<td>Use parameter name 'group' or 'groups' to specify one or more groups whose Confluence users you want to list, using a comma-separated list of group names. To see all users registered in a Confluence installation, specify an asterisk ('*') for this parameter's value.</td>
</tr>
<tr>
<td>Display Online/Offline Users</td>
<td>no</td>
<td>none</td>
<td>Specify 'true' to generate a list of online users. Specify 'false' to generate a list of offline users.</td>
</tr>
</tbody>
</table>

#### Parameters

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

- **Bold** Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in **Bold** text, while their equivalents in wiki markup are indicated in (bracketed) text. If the latter is not shown, then in wiki markup, the parameter's name should be omitted and only its value should be added immediately after the colon symbol (:).

#### Examples

**Listing all Users**

Here is an example that lists all the users registered on your Confluence site.

```plaintext
{userlister:groups=*}
```

**Specifying a Group**

Here is an example that lists the users that belong to the group 'my-staff'.

```plaintext
{userlister:groups=my-staff}
```

**Listing Only Online Users**

In order to make this feature functional, a System Administrator needs to enable the User Log In Listener for your Confluence site.

Here is an example that lists all currently online users in the 'my-staff' group.

```plaintext
{userlister:groups=my-staff|online=true}
```
List of online users can be misleading

When the parameter ‘online=true’ is used, Confluence uses a context listener to generate the list of online users. A context listener is a J2EE term for something that listens for events in the application server. We listen for session open and close events, so a user is ‘online’ if they have a session on the application server. Some application servers don’t correctly despatch close events for sessions – in these cases, the list of online users may be misleading.

Parameters

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in **Bold** text, while their equivalents in wiki markup are indicated in *(bracketed)* text. If the latter is not shown, then in wiki markup, the parameter's name should be omitted and only its value should be added immediately after the colon symbol (:).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required in Wiki Markup?</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Username</td>
<td>yes</td>
<td>none</td>
<td>The username of the Confluence user whose history of Status Updates you wish to show.</td>
</tr>
</tbody>
</table>

If you wish to list status updates made by more than just one user, you can use the **recently updated macro** in conjunction with the following parameter-value combinations:

- Include these Content Types Only — **status**
- Author(s) by username — the user(s) whose status updates you want to include in the list. If you leave this field blank, the status updates of all users will be included.

**RELATED TOPICS**

- Working with Macros
View File Macro

The view file macro allows you to embed an Office or PDF document into your Confluence page. First attach the document to a wiki page and then use the view file macro to display the document's content.

When viewing the page, users will see the content of the Office document. Users do not need to have Office installed, in order to see the content of the Office document.

Where applicable, users will be able to open the document for editing in their Office application.

This is just one of the ways Confluence can interact with Office documents. For an overview of all Office Connector features, please refer to Working with the Office Connector.

The view file macro provides several unique parameter options for some of the types of files it handles. Hence, to simplify its use, the view file macro is separated into the following four macros in the macro browser:

- Office Word
- Office Powerpoint
- Office Excel
- View PDF

On this page:

  - Basic Usage with the Wiki Markup Editor (pdf)
  - Parameters (pdf)
  - Viewing the PDF Document
- Troubleshooting

Basic Usage without the Macro Browser

To use the view file macro without the macro browser, enter it directly in the Wiki Markup or Rich Text editors based on one of the following examples, along with any parameters (described below) that suit the type of file.

```
{viewdoc:name=my document.doc}
{viewppt:name=my presentation.ppt}
{viewxls:name=my spreadsheet.xls}
{viewpdf:name=my document.pdf}
```

**Editing 'older style' {viewfile} macros**

In Confluence 3.0, the {viewfile} macro's syntax was changed to be file type-specific (as indicated by the examples above). If your Confluence site was upgraded to Confluence 3.0 and you had existing content which used the 'older style' syntax for this macro ({viewfile}), you can still edit these macros via the macro browser. Just place your cursor inside the viewfile macro's braces and click the macro browser icon to edit it. The 'edit only' version of the view file macro will open in the macro browser, allowing you to edit its specific parameters.

Example of Usage

The live example below shows how to display an Excel spreadsheet on a Confluence page. The Excel spreadsheet is attached to this
Prerequisites for Viewing and Displaying Office Documents

If you want to make use of the View File macro or to view Office documents attached to a wiki page, you need the setup described below.

**Browsers and Flash Player**

You can use any browser to view an Office document on a wiki page, provided that you have installed Adobe Flash Player version 9 or later. You do not need to have an Office desktop application installed on your computer, in order to view Office documents in Confluence.

**Document Types**

To be displayed in Confluence, the document needs to be valid Microsoft Office 97-2003 document, of the following types:

- .doc
- .xls
- .ppt
- .pdf

If you are using OpenOffice to create and edit the documents, you will need to save your document in Microsoft Office 97-2003 format before attaching it to a Confluence page.

Above are the prerequisites for viewing or displaying Office documents in Confluence. For a full list of Office Connector prerequisites and limitations, please refer to:

- Office Connector Prerequisites
- Office Connector Limitations and Known Issues

**Displaying a Word Document in Confluence**

**Usage with the Macro Browser (doc)**

To insert the Office Word macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'insert' to put the macro into the page.

Once you have found the Office Word macro and have added the required parameter values, click 'insert' to add it to your page.

**Basic Usage with the Wiki Markup Editor (doc)**

```markdown
{viewdoc:name=my document.doc}
```

**Parameters (doc)**

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

<table>
<thead>
<tr>
<th>Task</th>
<th>Monday</th>
<th>Tuesday</th>
<th>Wednesday</th>
<th>Thursday</th>
<th>Friday</th>
<th>Saturday</th>
</tr>
</thead>
<tbody>
<tr>
<td>Planning</td>
<td>5</td>
<td>3</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Design</td>
<td>3</td>
<td>5</td>
<td>2</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Development</td>
<td>6</td>
<td>5</td>
<td>5</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Testing</td>
<td>2</td>
<td>3</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Admin</td>
<td></td>
<td>1</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in **Bold** text, while their equivalents in wiki markup are indicated in *(bracketed)* text. If the latter is not shown, then in wiki markup, the parameter’s name should be omitted and only its value should be added immediately after the colon symbol (:).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required?</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>File Name</strong>&lt;br&gt;(name)</td>
<td>yes</td>
<td>none</td>
<td>The file name of the Office Word document to be displayed. The document must be attached to a wiki page on your Confluence site.</td>
</tr>
<tr>
<td><strong>Page Name</strong>&lt;br&gt;(page)</td>
<td>no</td>
<td>The page which contains the {viewdoc} macro</td>
<td>Enter a page name, if you wish to display a document which is attached to another Confluence page. For example:</td>
</tr>
<tr>
<td><strong>Space Key</strong>&lt;br&gt;(space)</td>
<td>no</td>
<td>The space of the page which contains the {viewdoc} macro</td>
<td>Enter a space key, if you wish to display a document which is attached to a page in another Confluence space. For example:</td>
</tr>
<tr>
<td><strong>Date</strong>&lt;br&gt;(date)</td>
<td>no</td>
<td>none</td>
<td>If the Page Name refers to a blog post instead of a conventional page, enter the date of the post in the form <code>mm/dd/yyyy</code>.</td>
</tr>
</tbody>
</table>

**Editing the Word Document**

When viewing a wiki page that displays an attached Office document, you can launch your Office editor directly from Confluence.

- Move your mouse pointer to the top of the document embedded in the Confluence page, until the hidden title bar appears. (See the screenshot below.)
- Click the title bar.
- Confirm your action and log in as prompted.
- The Office document will open in your Office application. Make any necessary changes, then save the document. It will be saved back into Confluence.

**Screenshot: The title bar showing 'document.doc' above an embedded Office document**

You will find detailed instructions in **Editing an Office Document from Confluence**.

**Displaying a PowerPoint Presentation in Confluence**

You can display an PowerPoint presentation on a Confluence page. By default, the presentation will be displayed as a dynamic slide show, using Adobe Flash Player. You can also choose to display just one of the slides as a static JPEG image.

**Usage with the Macro Browser (ppt)**

To insert the Office Powerpoint macro into a page using the Macro Browser,
1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'insert' to put the macro into the page.

Once you have found the Office Powerpoint macro and have added the required parameter values, click 'insert' to add it to your page.

Basic Usage with the Wiki Markup Editor (ppt)

```
{viewppt:name=my presentation.ppt}
```

Parameters (ppt)

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in **Bold** text, while their equivalents in wiki markup are indicated in *(bracketed)* text. If the latter is not shown, then in wiki markup, the parameter's name should be omitted and only its value should be added immediately after the colon symbol (:).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required?</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>File Name <em>(name)</em></td>
<td>yes</td>
<td>none</td>
<td>This file name of the Office Excel document to be displayed. The document must be attached to a wiki page on your Confluence site.</td>
</tr>
<tr>
<td>Height <em>(height)</em></td>
<td>no</td>
<td></td>
<td>Specify the height of the display, in pixels (default) or as a percentage of the window's height. For example, to specify a height of 200 pixels:</td>
</tr>
</tbody>
</table>

{viewppt:name=my presentation.ppt|height=200}
``` |
| | | | This code also specifies a height of 200 pixels: |
| | | | ```
{viewppt:name=my presentation.ppt|height=200px}
``` |
| | | | This code specifies a height of 10 percent of the window’s height: |
| | | | ```
{viewppt:name=my presentation.ppt|height=10%}
``` |
| Page Name *(page)* | no | The page which contains the {viewppt} macro | Enter a page name, if you wish to display a document which is attached to another Confluence page. For example: |
| | | | ```
{viewppt:name=my presentation.ppt|page=Sample Page}
``` |
| Slide Number *(slide)* | no | none | Specify the number of the slide which you want displayed on the Confluence page, starting with '0' for the first slide. Instead of a slide show, the page will display just the single slide represented as a JPEG image. |
| Space Key *(space)* | no | The space of the page which contains the {viewppt} macro | Enter a space key, if you wish to display a document which is attached to a page in another Confluence space. For example: |
| | | | ```
{viewppt:name=my presentation.ppt|space=DOC|page=Sample Page}
``` |
Confluence 3.0 Documentation

| Width (width) | no | Specify the width of the display, in pixels (default) or as a percentage of the window's width. For example, to specify a width and height of 200 pixels:
| {viewppt:name=my presentation.ppt|width=200|height=200} |
| This code also specifies a width and height of 200 pixels:
| {viewppt:name=my presentation.ppt|width=200px|height=200px} |
| This code specifies a width of 10 percent of the window's width:
| {viewppt:name=my presentation.ppt|width=10%} |

| Date (date) | no | none |
| If the Page Name refers to a blog post instead of a conventional page, enter the date of the post in the form mm/dd/yyyy.

Viewing the Slide Show and Editing the Presentation

When you view the PowerPoint presentation on a Confluence page, options on the bottom frame of the slide show allow you to:

- Download the presentation and save it onto your computer.
- Edit the presentation in your Office application. You will find detailed instructions in Editing an Office Presentation from Confluence.
- Move to the first, previous, next and last slides in the presentation. Or enter a slide number to move directly to that slide.
- Refresh the display.
- Open the presentation in full-screen mode. To return to normal viewing mode, press the escape key (Esc) on your keyboard.

Displaying an Excel Spreadsheet in Confluence

Usage with the Macro Browser (xls)

To insert the Office Excel macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'insert' to put the macro into the page.

Once you have found the Office Excel macro and have added the required parameter values, click 'insert' to add it to your page.

Basic Usage with the Wiki Markup Editor (xls)

{viewxls:name=my spreadsheet.xls}

Parameters (xls)

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in Bold text, while their equivalents in wiki markup are indicated in (bracketed) text. If the latter is not shown, then in wiki markup, the parameter's name should be omitted and only its value should be added immediately after the colon symbol (:).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required?</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
</table>

1501
**File Name**  
*name*  
**yes**  
none  
This is the file name of the document to be displayed. The document must be attached to a wiki page on your Confluence site.

**Last Column**  
*col*  
**no**  
Last column with content  
Enter the number of the last column you want displayed, starting from '0' as the first column. For example, the following code will show the first 3 rows and the first 3 columns:

```
{viewxls:name=my spreadsheet.xls|col=2|row=2}
```

**Show Grid?**  
*grid*  
**no**  
true  
Select the check box in the macro browser (true in Wiki Markup) to show grid lines around each cell of the Excel spreadsheet. Clear the check box in the macro browser (false in Wiki Markup) to hide these grid lines.

**Page Name**  
*page*  
**no**  
The page which contains the {viewxls} macro  
Enter a page name, if you wish to display a document which is attached to another Confluence page. For example:

```
{viewxls:name=my spreadsheet.xls|page=Sample Page}
```

**Last Row**  
*row*  
**no**  
Last row with content  
Enter the number of the last row you want displayed, starting from '0' as the first row. For example, the following code will show the first 3 rows and the first 3 columns:

```
{viewxls:name=my spreadsheet.xls|col=2|row=2}
```

**Worksheet Name**  
*sheet*  
**no**  
The first worksheet in the spreadsheet  
Enter the name of the worksheet that you want displayed.

**Space Key**  
*space*  
**no**  
The space of the page which contains the {viewxls} macro  
Enter a space key, if you wish to display a document which is attached to a page in another Confluence space. For example:

```
{viewxls:name=my spreadsheet.xls|space=DOC|page=Sample Page}
```

**Date**  
*date*  
**no**  
none  
If the **Page Name** refers to a blog post instead of a conventional page, enter the date of the post in the form **mm/dd/yyyy**.

### Editing the Excel Spreadsheet

When viewing a wiki page that displays an attached Office spreadsheet, you can launch your Office editor directly from Confluence.

- Move your mouse pointer to the top of the spreadsheet embedded in the Confluence page, until the hidden title bar appears. (See the screenshot below.)
- Click the title bar.
- Confirm your action and log in as prompted.
- The spreadsheet will open in your Office application. Make any necessary changes, then save the spreadsheet. It will be saved back into Confluence.

*Screenshot: The title bar showing 'spreadsheet.xls' above an embedded Excel spreadsheet*
1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'Insert' to put the macro into the page.

Once you have found the View PDF macro and have added the required parameter values, click 'Insert' to add it to your page.

**Basic Usage with the Wiki Markup Editor (pdf)**

```
{viewpdf:name=my_document.pdf}
```

**Parameters (pdf)**

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in **Bold** text, while their equivalents in wiki markup are indicated in *(bracketed)* text. If the latter is not shown, then in wiki markup, the parameter’s name should be omitted and only its value should be added immediately after the colon symbol (:).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required?</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>File Name</td>
<td>yes</td>
<td>none</td>
<td>This is the file name of the document to be displayed. The document must be attached to a wiki page on your Confluence site.</td>
</tr>
<tr>
<td>Page Name</td>
<td>no</td>
<td>The page which contains the {viewpdf} macro</td>
<td>Enter a page name, if you wish to display a document which is attached to another Confluence page. For example:</td>
</tr>
<tr>
<td>Space Key</td>
<td>no</td>
<td>The space of the page which contains the (viewpdf) macro</td>
<td>Enter a space key, if you wish to display a document which is attached to a page in another Confluence space. For example:</td>
</tr>
</tbody>
</table>
Viewing the PDF Document

When you view the PDF document on a Confluence page, it is displayed as a slide show. Options on the bottom frame of the slide show allow you to:

- Download the PDF file and save it onto your computer.
- Move to the first, previous, next and last pages in the document. Or enter a page number to move directly to that page.
- Refresh the display.
- Open the document in full-screen mode. To return to normal viewing mode, press the escape key (‘Esc’) on your keyboard.

**RELATED TOPICS**

- Working with Macros

Take me back to the [Confluence User Guide](#).

**Web-Widget Macro**

The **Web-Widget** macro is just another name for the **Widget macro**.

Confluence supports `web-widget` as an alias for `widget`. Your **System Administrator** can enable or disable one or both these macro names. The alias is useful for Confluence sites which use Adaptavist's **Community Bubbles plugin**, to avoid conflict with the 'widget' macro supplied by that plugin.

If the `web-widget` alias is enabled on your Confluence site, you can use `web-widget` instead of `widget` in all the examples given in the page about the **Widget macro**.

**RELATED TOPICS**
Welcome Message macro

The **Welcome Macro** allows you to include the Confluence site welcome message in your page.

The welcome message is configured by a **Confluence administrator** from the **Administration Console**.

Widget Macro

The Widget macro, or Widget Connector, allows you to embed multi-media content from other web sites into your Confluence page.

It supports content such as:

- Gadgets and other widgets: Google Gadgets, Widgetbox.
- Videos: YouTube, MySpace Video, Google Video, Yahoo Video, Dailymotion, Episodic, Vimeo, Metacafe, blip.tv, Viddler.
- Photos and images: Flickr, Skitch.com.
- Micro-blogging: Twitter, FriendFeed, BackType.
- Documents and presentations: SlideShare, SlideRocket, Scribd, presentations on Google Docs.
- Calendars: Google Calendar.
- Forms and online databases: Wufoo HTML Form Builder, Dabble DB.

On this page:

- About the Web-Widget and Widget Macros
- Troubleshooting

Usage with the Macro Browser

To insert the Widget macro into a page using the Macro Browser,

1. Open your desired Confluence page, then click the 'Edit' button. The 'Edit Page' mode opens.
2. Next, click the Macro Browser icon on the editor toolbar. The Macro Browser will open in the middle of the screen.
3. In the Macro Browser, type the name of your desired macro into the search box at the top right of the window. Macros with a matching name will appear in the centre pane. Click on the desired macro to see its options screen. Here, you can set the macro parameters then click 'Insert' to put the macro into the page.

Once you've found the Widget macro and have added the required parameter values, click 'Insert' to add it to your page.

Usage with the Wiki Markup Editor

Just type the word 'widget' in curly brackets, and give it the URL (web address) of the thing you want to display.

```
{widget:url=http://example.com/my-location}
```

If the web-widget alias is enabled on your Confluence site, you can use web-widget instead of widget. See below.

Parameters

Parameters are settings for Confluence macros that allow the user to control their content or presentation. The table below lists relevant parameters for this macro.

Parameter names are displayed differently in the macro browser interface and in wiki markup. Below, parameter names used in the macro browser are indicated in **Bold** text, while their equivalents in wiki markup are indicated in (bracketed) text. If the latter is not shown, then in wiki markup, the parameter’s name should be omitted and only its value should be added immediately after the colon symbol (:)..

</tr>
</tbody>
</table>

**Live Example of Flickr Photos**

This example shows the Widget macro in action. It displays all photos from Flickr with the tag ‘Atlassian’.

**What You Need to Type**

```
{widget:url=http://www.flickr.com/photos/tags/atlassian/height=200}
```

**What You Will Get**

**Live Example of Google Gadget**

This example shows the Widget macro in action. It lets you play with a Google Gadget, Gadzi’s Monkey Virtual Pet.

**What You Need to Type**

```
{widget:url= http://www.google.com/ig/adde?synd=open&amp;source=ggyp&amp;moduleurl=www.gadzi.com/gadgets/monkey.xml|width=250}
```

**What You Will Get**

**More Examples of Macro Code**

**Google Gadgets**

You will need to find the URL for the Google Gadget you want to display.

Here is one way to find a gadget’s URL:

1. Go to the Google Gadgets directory.
2. Find the gadget you want then click its name, such as 'Spider'.
3. The gadget's summary page will open. Copy the URL from your browser's address bar. The URL looks something like this one:

```
http://www.google.com/ig/directory?synd-open&num=24&url=
http://abowman.googlepages.com/spider.xml&amp;output=html
```

4. Paste the URL into the Widget macro code on your Confluence page.

You can also use the URL of the 'add gadget' page. The page is called 'Add "gadgetx" to your iGoogle page':

1. There are a couple of ways to get to the 'add gadget' page:
   - Click a '+Google' button underneath the gadget when displayed on a page somewhere.
   - Or click 'Add Stuff' on your iGoogle page.
2. Copy the URL from your browser's address bar. The URL would look something like this one:

```
http://www.google.com/ig/adde?synd-open&
;source=ggyp&amp;moduleurl=abowman.googlepages.com/spider.xml
```

Here is an example of the Widget macro code for embedding a Google Gadget:

```
{widget:url=http://www.google.com/ig/adde?synd-open&
;source=ggyp&amp;moduleurl=abowman.googlepages.com/spider.xml}
```

**Widgetbox widgets**

You will need to find the URL for the Widgetbox widget you want to display.

Here is one way to find a widget's URL:

1. Ensure you are logged in to Widgetbox and that you are viewing the Widgetbox Gallery.
2. Find the widget you want then click its name, such as 'cyber-pet'.

3. The widget's summary page will open. Within the Get Widget section, click the Atlassian Confluence icon. The Widgetbox Add to Confluence dialog box appears, containing the URL required for the Widget Macro.
   - If you cannot see this icon, click the more... link to reveal it.
4. In the Widgetbox Add to Confluence dialog box, click the Copy button.
5. Copy the URL from your browser's address bar. The URL looks something like this one:

```
http://widgetbox.com/confluence/b8327e33-c8eb-4a38-b842-fba86ffdd28
```

6. Paste the URL into the Widget macro code on your Confluence page.

Here is an example of the Widget macro code for embedding a Widgetbox widget:

```
{widget:url=http://widgetbox.com/confluence/b8327e33-c8eb-4a38-b842-fba86ffdd28}
```

**YouTube**

You will need to find the URL for the YouTube video that you want to display.

To find a YouTube video's URL:

1. Go to YouTube and search for the video you want.
2. Click the title of the video, such as 'Wikis in Plain English'.
3. The video's summary page will open. Copy the URL from your browser's address bar. The URL looks something like this one:

```
http://au.youtube.com/watch?v=-dnL00TdmLY
```

4. Paste the URL into the Widget macro code on your Confluence page.

Here is an example of the Widget macro code for embedding a YouTube video:

```
{widget:url=http://au.youtube.com/watch?v=-dnL00TdmLY}
```
**MySpace Videos**

You will need to find the URL for the MySpace video that you want to display.

**To find a MySpace video’s URL:**

1. Go to [MySpace Video](http://www.myspace.com) and search for the video you want.
2. Click the title of the video, such as 'Glacier Creek Confluence Time Lapse'.
3. The video’s summary page will open. Copy the URL from your browser’s address bar. The URL looks something like this:

   ![MySpace Video URL Example](http://vids.myspace.com/index.cfm?fuseaction=vids.individual&videoid=3376248&searchid=20c789f6-1ae9-459a-bfec-75efcfc2847c)

4. Paste the URL into the Widget macro code on your Confluence page.

Here is an example of the Widget macro code for embedding a MySpace video:

```html
{widget:url=http://vids.myspace.com/index.cfm?fuseaction=vids.individual&videoid=3376248&searchid=20c789f6-1ae9-459a-bfec-75efcfc2847c}
```

**Google Video**

You will need to find the URL for the Google video that you want to display.

**To find a Google video’s URL:**

1. Go to [Google Video](http://www.youtube.com) and search for the video you want.
2. Click the title of the video, such as 'An Evening With Wiki Inventor Ward Cunningham in Conversation'.
3. The video’s summary page will open. Copy the URL from the address bar of your browser. The URL looks something like this:

   ![Google Video URL Example](http://video.google.com/videoplay?docid=-7739076742312910146&ei=nJAfSbrzPIWogwOhv_GKDA&q=An+Evening+With+Wiki+Inventor+Ward+Cunningham+in+Conversation&emb=1)

4. Paste the URL into the Widget macro code on your Confluence page.

Here is an example of the Widget macro code for embedding a Google video:

```html
{widget:url=http://video.google.com/videoplay?docid=-7739076742312910146&ei=nJAfSbrzPIWogwOhv_GKDA&q=An+Evening+With+Wiki+Inventor+Ward+Cunningham+in+Conversation&emb=1}
```

**Yahoo Video**

You will need to find the URL for the Yahoo video that you want to display.

**To find a Yahoo video’s URL:**

1. Go to [Yahoo Video](http://www.yahoo.com) and search for the video you want.
2. Click the title of the video, such as 'Wiki Technology Trend: Past, Now and Future'.
3. The video’s summary page will open. Copy the URL from the address bar of your browser. The URL looks something like this:

   ![Yahoo Video URL Example](http://video.yahoo.com/watch/423158/2424140)

4. Paste the URL into the Widget macro code on your Confluence page.

Here is an example of the Widget macro code for embedding a Yahoo video:

```html
{widget:url=http://video.yahoo.com/watch/423158/2424140}
```

**Dailymotion Video**

You will need to find the URL for the Dailymotion video that you want to display.

**To find a Dailymotion video’s URL:**

1. Go to [Dailymotion Video](http://www.dailymotion.com) and search for the video you want.
2. Click the title of the video, and it will take you to the video’s summary page.
3. Copy the URL from the address bar. The URL looks something like this:

   ![Dailymotion Video URL Example](http://vids.myspace.com/index.cfm?fuseaction=vids.individual&videoid=3376248&searchid=20c789f6-1ae9-459a-bfec-75efcfc2847c)

4. Paste the URL into the Widget macro code on your Confluence page.

Here is an example of the Widget macro code for embedding a Dailymotion video:

```html
{widget:url=http://vids.myspace.com/index.cfm?fuseaction=vids.individual&videoid=3376248&searchid=20c789f6-1ae9-459a-bfec-75efcfc2847c}
```
1. Go to Dailymotion and search for the video you want.
2. Click the title of the video, such as 'Wiki Technology Trend: Past, Now and Future'.
3. The video's summary page will open. Copy the URL from the address bar of your browser. The URL looks something like this:

   http://www.dailymotion.com/user/spacevidcast/video/x7zevj_spacevidcast-2009-promo-video_tech

   If you are unable to obtain a unique URL from your browser's address bar, click Menu at the lower right section of the video screen, select URL & Embed Code and copy the contents of the Link field.

4. Paste the URL into the Widget macro code on your Confluence page.

Here is an example of the Widget macro code for embedding a Dailymotion video:

   {widget: http://www.dailymotion.com/user/spacevidcast/video/x7zevj_spacevidcast-2009-promo-video_tech}

Episodic
You will need an Episodic user account if you want to create and distribute videos via Episodic.

To embed an Episodic video onto a Confluence page:

1. Find the video and copy the URL from the address bar of your browser. The URL looks something like this:

   http://app.episodic.com/shows/13/episodes/493

2. Paste the URL into the Widget macro code on your Confluence page.

Here is an example of the Widget macro code for embedding an Episodic video:

   {widget:url=http://app.episodic.com/shows/13/episodes/493}

Vimeo
You will need to find the URL for the Vimeo video that you want to display.

To find a Vimeo video's URL:

1. Go to Vimeo and search for the video you want.
2. Click the title of the video, such as 'The Wiki Show - Allison the Russian High Kicker'.
3. The video's summary page will open. Copy the URL from the address bar of your browser. The URL looks something like this:

   http://www.vimeo.com/909808

4. Paste the URL into the Widget macro code on your Confluence page.

Here is an example of the Widget macro code for embedding a Vimeo video:

   {widget:url=http://www.vimeo.com/909808}

Metacafe
You will need to find the URL for the Metacafe video that you want to display.

To find a Metacafe video's URL:

1. Go to Metacafe and search for the video you want.
2. Click the title of the video, such as 'Wikis In Plain English (How To)'.
3. The video's summary page will open. Copy the URL from the address bar of your browser. The URL looks something like this:

   http://www.metacafe.com/watch/679493/wikis_in_plain_english_how_to/

4. Paste the URL into the Widget macro code on your Confluence page.
Here is an example of the Widget macro code for embedding a Metacafe video:

```
{widget:url=http://www.metacafe.com/watch/679493/wikis_in_plain_english_how_to/}
```

**blip.tv**

You will need to find the URL for the blip.tv video that you want to display.

To find a blip.tv video's URL:

1. Go to [blip.tv](http://blip.tv) and search for the video you want.
2. Click the title of the video, such as 'River cruising on the Rhine'.
3. The video's summary page will open. Copy the URL from the address bar of your browser. The URL looks something like this one:

   ![URL Example](http://blip.tv/file/996864/)

4. Paste the URL into the Widget macro code on your Confluence page.

Here is an example of the Widget macro code for embedding a blip.tv video:

```
{widget:url=http://blip.tv/file/996864/}
```

The Widget Connector packaged with Confluence 3.0 currently possesses issues rendering blip.tv videos on Confluence pages. This problem has already been recorded in CONF-15667.

**Viddler**

You will need to find the URL for the Viddler video that you want to display.

To find a Viddler video's URL:

1. Go to [Viddler](http://www.viddler.com) and search for the video you want.
2. Click the title of the video, such as 'Gliffy Diagramm in Conflu...'.
3. The video's summary page will open. Copy the URL from the address bar of your browser. The URL looks something like this one:

   ![URL Example](http://www.viddler.com/explore/Markus_Z/videos/1/)

4. Paste the URL into the Widget macro code on your Confluence page.

Here is an example of the Widget macro code for embedding a Viddler video:

```
{widget:url=http://www.viddler.com/explore/Markus_Z/videos/1/}
```

**Flickr**

You can embed a slide show of photos from Flickr by supplying a URL that specifies one of the following:

- Photos with a specific tag.
- Photos belonging to the photostream of a specific Flickr user.
- A set of photos as defined by the Flickr user.
- A user's photostream starting at a specific photo.

If you want to do something else, we suggest that you try any Flickr URL. It should work.

Below are some examples of the Widget macro code for embedding Flickr images.

**Flickr Photos with a Specific Tag**

This example displays a slide show of Flickr photos that are tagged with the word 'Atlassian'.

```
{widget:url=http://www.flickr.com/photos/tags/atlassian/}
```

**Flickr Photos from a Specific User**
This example displays a slide show of photos from the Flickr photostream of user 'Atlassian'.

Flickr Photos from a Specific Set

This example displays a slide show of Flickr photos from the set 'Melbourne Cup - November 2008' created by user 'Atlassian'.

A Specific Flickr Photo

This example displays a slide show of photos from the Flickr photostream of the user 'Atlassian', starting with a specific photo.

Skitch.com

You will need to find the URL for the Skitch image that you want to display.

To embed a Skitch image onto a Confluence page:

2. Find the image and copy the URL from the address bar of your browser. The URL looks something like this:

   http://skitch.com/atlassian/411g/example-image

3. Paste the URL into the Widget macro code on your Confluence page.

Here is an example of the Widget macro code for embedding a Skitch image:

Twitter

To display the latest messages from a Twitter user, add the user's Twitter link as a URL in the Widget macro.

The example below will display Mike Cannon-Brooke's Twitter messages:

FriendFeed

To display the latest messages from a FriendFeed user, add the user's FriendFeed link as a URL in the Widget macro. For example:

BackType

To display the latest blog or website comments from a BackType user, add the user's BackType widget link as a URL in the Widget macro. For example:

SlideShare
You will need to find the URL for the SlideShare presentation that you want to display.

To find a SlideShare presentation's URL:
1. Go to SlideShare and search for the presentation you want.
2. Click the title of the presentation, such as 'Using JIRA & Greenhopper for Agile Development'.
3. The presentation's summary page will open. Copy the URL from the address bar of your browser. The URL looks something like this one:

   http://www.slideshare.net/jleyser/using-jira-greenhopper-for-agile-development-presentation

4. Paste the URL into the Widget macro code on your Confluence page.

Here is an example of the Widget macro code for embedding a SlideShare presentation:

   {widget:url=http://www.slideshare.net/jleyser/using-jira-greenhopper-for-agile-development-presentation}

SlideRocket

You will need to find the URL for the SlideRocket presentation that you want to display.

To find a SlideRocket presentation's URL:
1. Log in to SlideRocket and go to your library of presentations.
2. Copy the 'web link' for the presentation you want to display. This will give you a URL that looks something like this one:

   http://app.sliderocket.com/app/FullPlayer.aspx?id=132f9db7-b0fb-4f51-b974-36652774971b

3. Paste the URL into the Widget macro code on your Confluence page.

Here is an example of the Widget macro code for embedding a SlideRocket presentation:

   {widget:url=http://app.sliderocket.com/app/FullPlayer.aspx?id=132f9db7-b0fb-4f51-b974-36652774971b}

Scribd

You will need to find the URL for the Scribd presentation that you want to display.

To find a Scribd presentation's URL:
1. Go to Scribd and search for the presentation you want.
2. Click the title of the presentation, such as 'My Sea Friends Coloring Book'.
3. The presentation's summary page will open. Copy the URL from the address bar of your browser. The URL looks something like this one:

4. Paste the URL into the Widget macro code on your Confluence page.

Here is an example of the Widget macro code for embedding a Scribd presentation and displaying it with a height of 600 pixels:

Google Docs Presentations

You can embed presentations from Google Docs, but not other document types. You will need to find the URL for the Google Docs presentation that you want to display.

To find the URL of a Google Docs presentation:
1. Publish your presentation in Google Docs.
2. View your published document, then copy the URL from your browser's address bar. The URL will look something like this:
3. Paste the URL into the Widget macro code on your Confluence page.

Here is an example of the Widget macro code for embedding a Google Docs presentation:

```
{widget:url=http://docs.google.com/Presentation?docid-ddpqn8g5_0fx96zmmq&amp:mm=en_GB}
```

**Google Calendar**

You can embed a Google Calendar into your page and to do this, you will need to add the URL for the Google Calendar that you want to display.

To find the URL for a Google Calendar:

1. Log in to Google Calendar.
2. In the calendar list on the left side of the page, ensure the appropriate calendar is selected, click the down-arrow button next to the calendar name and then select the **Calendar settings** option. (Alternatively, if available, click the **Manage Calendars** link at the bottom of the calendar list and then click the name of the appropriate calendar.)
3. In the **Calendar Address** section, click the **HTML** button. A pop-up message with your calendar’s public URL appears.
4. Copy the URL from this pop-up message. The URL looks something like this:

```
http://www.google.com/calendar/embed?src=somebody%40example.com&amp;ctz=Australia/Sydney
```

5. Paste the URL into the Widget macro code on your Confluence page.

Here is an example of the Widget macro code for embedding a Google Calendar:

```
{widget:url=http://www.google.com/calendar/embed?src=somebody%40example.com&amp ;ctz=Australia/Sydney}
```

**Wufoo HTML Form Builder**

To display an HTML form built in the Wufoo **HTML Form Builder**, add the form’s link as a URL to the Widget Macro. For example:

```
{widget:url=http://examples.wufoo.com/forms/contact-form/}
```

**Dabble DB online database builder**

To display a shared page built in Dabble DB, add the page’s link as a URL to the Widget Macro. For example:

```
{widget:url=https://confluence-sample.dabbledb.com/page/confluence-sample/nSQqdgIg}
```

The Widget Macro supports shared Dabble DB **view** and **form** pages. Hence, it is possible to insert a Dabble DB data entry form into a Confluence page. Any data submitted via this form can be displayed on the same or another page via a Dabble DB view.

**About the Web-Widget and Widget Macros**

Confluence supports **web-widget** as an alias for widget. Your **System Administrator** can enable or disable one or both these macro names. The alias is useful for Confluence sites which use Adaptavist’s **Community Bubbles** plugin, to avoid conflict with the ‘widget’ macro supplied by that plugin.

If the **web-widget** alias is enabled on your Confluence site, you can use **web-widget** instead of **widget** in all the examples above.

**Troubleshooting**

If the URL given in the Widget macro does not work, the Widget macro displays an icon and the base URL. The icon will be linked to the full URL given in the macro code.

For example, the following code:
This page contains a working example of all the services currently supported by the Widget Connector. This page lets you preview what each widget will look like and see how to interact with it.

**Flickr**

```
{widget:url=http://example.com/invalid}
```

```
{widget:url=http://www.flickr.com/photos/tags/atlassian}
```

```
{widget:url=http://www.flickr.com/photos/atlassian/}

- Working with Macros

Working with the Macro Browser

The **Macro Browser** allows you to browse through Confluence's extensive range of packaged macros and preview them using a combination of selected parameters before adding them to your page.

The Macro Browser provides access to **all available macros** in a Confluence installation, with the exception of **User Macros**. If additional Confluence macros have been installed on your Confluence server (for example, via the installation of a non-bundled plugin), these will also be accessible from the Macro Browser.

On this page:

- Accessing the Macro Browser
- Browsing for a Macro
  - Restricting the Macro List by Category
  - Restricting the Macro List by Word Search
- Choosing a Macro, Modifying and Inserting it onto a Page or Blog Post
- Editing an Existing Macro with the Macro Browser

Accessing the Macro Browser

You can access the Macro Browser whenever you add or edit a page, blog post or comment.

To access the Macro Browser,

1. Log in to Confluence, if you have not already done so.
2. Add or edit a page or blog post.
3. On either the **Rich Text** or **Wiki Markup** editor views, place the cursor at the macro insertion point and click the Macro Browser icon .
   Alternatively, if you are working in the Rich Text editor and have the **Context Menu** activated, place the cursor at the macro insertion point, right-click and select `Insert/Edit Macro` from the Context Menu.

   The Macro Browser window opens.
Each macro is presented on the right-hand side of the Macro Browser by its icon, its name and a brief description of its function.

**Browsing for a Macro**

Since the Macro Browser contains 80+ individual bundled macros, it is designed to facilitate the selection of the specific macro you require, by providing two quick methods for narrowing down the entire list of macros. When the Macro Browser is first opened, it is in 'macro selection' mode.

**Restricting the Macro List by Category**

Each macro is assigned to one of these categories. Clicking on one of these category names reduces the list of macros to those macros associated with the chosen category only.

**Screenshot: Macro Browser List Restricted by Category**

A very small proportion of macros are assigned to two (or rarely three) categories because their scope of functionality matches these categories. Hence, you may notice that some of these macros are appearing in two, possibly three categories.

**Restricting the Macro List by Word Search**

The search field at the top of the Macro Browser allows you to reduce the list of macros based on words (or parts of words) contained within the macro's name or its description. As you start typing a word, the macro list restricts to only those macros whose name or description matches the characters you have entered.
Choosing a Macro, Modifying and Inserting it onto a Page or Blog Post

To choose a macro, modify and insert it onto a page or blog post,

1. Access the Macro Browser and browse to the required macro, if you have not already done so.
2. Click on the required macro to choose it. The Macro Browser window changes to the macro preview mode with its preview pane on the left and parameter pane on the right.
3. If necessary, modify the macro's parameters in the parameter pane to your requirements.
   - Any parameters marked by an asterisk (*) are mandatory and must be set before you can preview or insert the macro.
4. To preview the macro with your selected parameters, click 'Refresh'. The preview pane shows the current content of your macro based on the parameters selected in the parameter pane.
   - Macros can only be previewed if their mandatory fields have first been set.
5. Click the 'Insert' button to insert the macro and its parameter selection into the page or blog post.
   - If you wish to choose a different macro, click the 'Back' button. The Macro Browser reverts back to its macro selection mode, based on your prior restriction by category or word search criteria.

Not all macros can be previewed in the Macro Browser. This is often the case with macros that require the page to be saved first to render correctly, such as the Table of Contents Macro, or macros that do not generate output, such as the Anchor Macro. Nevertheless, you can still use the Macro Browser to browse for these macros and set their specific parameters before inserting them into your page.

Editing an Existing Macro with the Macro Browser

It is possible to edit an existing macro using the Macro Browser, thereby allowing you to modify its existing parameters and preview the changes.

To edit an existing macro with the Macro Browser,

If multiple words (including partial words) are used, then only macros whose name or description matches all these items in the Word Search field are listed.
1. Edit the existing page or blog post containing the macro you wish to edit via the Rich Text or Wiki Markup editors.

2. Place the cursor anywhere within the curly braces of the macro and click the Macro Browser icon. Alternatively, if you are working in the Rich Text editor and have the Context Menu activated, place the cursor anywhere within the curly braces of the macro, right-click and select 'Insert/Edit Macro' from the Context Menu.

3. If the macro you wish to edit consists of two sets of curly braces surrounding some body text (for example, \{example-macro\}some body text\{example-macro\}), ensure that your cursor is placed within the macro’s first set of curly braces. This is because many macros permit the insertion of other macros within their bodies. If you are using the Rich Text Editor, you can also edit the macro by placing your cursor in its second set of curly braces. The Macro Browser window opens in macro preview mode with its existing parameter values.

4. Modify the macro’s parameters to your requirements, previewing them if necessary. For more information on these processes, refer to the procedure above.

5. Click the ‘Save’ button on the Macro Browser to save your changes.

To leave the Macro Browser at any time, click its ‘Cancel’ button or simply press the ESC key.

Working with Macros

Tracking Updates Overview

Here’s how you can keep track of changes to a single page, an entire space, or to all spaces on your site.

You can only track updates to content visible to you.

Watch a space: be notified by email of new or modified content within a space. The notifications contain:

- Pages created and updated
- Blog posts created and updated
- User profiles updated

Watch a page: be notified by email of updates to a page.

Subscribe to Daily Email Reports: be notified daily of changes in all spaces to which you have ‘view’ access.

RSS Feeds: subscribe to Confluence RSS feeds to stay informed of
Managing Watches

The 'Watches' page displays a list of all pages and spaces you are currently watching. You will be sent email notifications when changes are made to your watched pages and spaces.

To manage your notifications for your 'Watches',

1. Go to the 'Profile' view for your user profile. To do this:
   - Log in to Confluence, if you have not already done so.
   - Go to your name at the top of the page. (This is the 'User' menu. A dropdown list will appear when your cursor hovers over the 'User' menu.)
   - Select 'Profile' from the dropdown list. The 'Profile' view will open.
2. Go to the 'Watches' tab. This lists the pages and spaces you are currently watching. Click the envelope icon beside any unwanted watches to remove them.
3. Click the 'email settings' link to go to the 'Email' section of the 'Settings' tab.
4. Click the 'Edit' button to enter edit mode.
5. Select the 'Notify on my actions' check box if you want Confluence to include your own actions in your notifications for your watches. Clear this if you do not want to be notified of your own actions.
   - Note that this option only applies to your watches and not to the Daily Report.
6. Use the 'Email Format' drop-down menu to choose whether you want to receive your notifications as HTML or plain text. Note that this will apply to the Daily Report as well as to your notifications for watches.
7. Click the 'Save' button to save your changes.

RELATED PLUGINS

Consider adding a plugin to extend Confluence's functionality.

- Confluence Contributors Plugin — allows you to list the users, watchers, labels and etc in a page.
- Autowatch Plugin — allows you to automatically turn on the page watch if a comment is added.
1. Go to the 'Profile' view for your user profile. To do this:
   - Log in to Confluence, if you have not already done so.
   - Go to your name at the top of the page. (This is the 'User' menu. A dropdown list will appear when your cursor hovers over the 'User' menu.)
   - Select 'Profile' from the dropdown list. The 'Profile' view will open.
2. Click the 'Settings' tab.
3. In the left-hand panel, click the 'Email' link.
4. Click the 'Edit' button.
5. From the 'Email Format' drop-down menu, select whether you want to receive your notifications as HTML or plain text. This will apply to all your email notifications, including your watches.
6. Select the check box beside 'Subscribe to daily updates'.
7. If you want to receive a notification each time you add or edit content on Confluence yourself, select the check box beside 'Notify on my actions'. If you leave this check box cleared, you will receive notification of other people's actions but not of your own.
8. If you want to see content changes made in Edit notification email messages, select the check box beside 'Show changed content'. If you leave this check box cleared, content changes will be omitted from your emails.
9. If you want to see full page or blog post content in Edit notification emails, select the check box beside 'Show full content'. If you leave this check box cleared, full page or blog post content in Edit notification emails will be omitted from your emails.
10. Click the 'Submit' button.

Tracking Updates Overview
User Profile Overview

Take me back to the Confluence User Guide.

**Subscribing to RSS Feeds within Confluence**

RSS feeds allow you to track updates to content within Confluence. You will need an RSS newsreader to subscribe to them.

On this page:
- Confluence RSS Feeds
- RSS Newsreaders
• Removing an RSS Feed

Confluence RSS Feeds

You can create a customised RSS feed using the RSS Feed Builder (recommended) or subscribe to one of the pre-specified feeds generated by Confluence.

What would you like to do?

• Create and subscribe to customised RSS feeds using the RSS Feed Builder — create a customised RSS feed (e.g. filter your feed using a label; specify the number of items and days to include in your feed; etc.)

• Subscribe to pre-specified RSS feeds — generate an RSS feed automatically in a minimal number of steps.

• Subscribe to a feed of bookmarks created via the Social Bookmarking plugin.

• Subscribe to a feed of any Confluence user's network to track the activities of users they are following in their network.

To have your newsreader log into Confluence, you can add your username and password to the feed URL. But please note that if you do this, someone with access to your RSS newsreader configuration can read your password.

RSS Newsreaders

The following are some popular RSS newsreader programs for various operating systems. You can find a more comprehensive list on Google's open directory.

Windows

• SharpReader
• NewsGator
• Syndirella

Removing an RSS Feed

There is no need to try to delete or remove an RSS feed built by the Confluence RSS feed builder.

Explanation: The feeds generated by the RSS Feed Builder are dynamically generated via the parameters included in the feed URL (address). For example, take a look at the following feed URL:

http://confluence.atlassian.com/createrssfeed.action?types=page&sort=modified&showContent=true...

The above feed URL will generate a list of pages ("types=page"), sorted by the modification date and showing the page content. The feed is generated at the time when the URL is fetched and there is no RSS feed information stored on the database. For that reason, there is no need to remove anything.

Adding a username and password to Confluence RSS feeds

Take me back to the Confluence User Guide.
Using pre-specified RSS feeds

If you want to customise your Confluence RSS feed (e.g. use a label to filter your feed), use the RSS Feed builder instead.

To subscribe to RSS feeds generated by Confluence, for a particular space

1. Go to 'Browse' and select 'Advanced' from the dropdown list. The 'Advanced' screen will appear.
2. Click on 'RSS Feeds' in the left-hand column.
3. Copy and paste the link for one of the following feeds into your RSS newsreader:
   - Pages
   - News
   - Mail
   - Comments
   - Attachments
   - All content
4. To have your newsreader log into Confluence, you can add your username and password to the feed URL.
   Please note that if you do this, someone with access to your RSS newsreader configuration can read your password.

To subscribe to RSS feeds generated by Confluence, for a particular page (where available)

1. Locate the following icon, which is available in the top-right corner of certain pages: 📢
2. Copy and paste the icon's link into your RSS newsreader.
3. To have your newsreader log into Confluence, you can add your username and password to the feed URL.
   Please note that if you do this, someone with access to your RSS newsreader configuration can read your password.

Using the RSS Feed Builder

Using the RSS feed builder, you can create customised RSS feeds to subscribe to changes within Confluence.

More information about RSS Feeds.

Building an RSS Feed

To create a customised RSS feed,
1. Go to the dashboard and click on the RSS feed builder link located below the list of spaces. This will display a form as shown below.

2. **Type of Content**: Check the boxes to select one or more content types you want to subscribe to: Pages, News Items, Mail, Comments, and Attachments.

3. Choose whether to sort items in your RSS feed by the date they were originally **Created** or the date they were last **Modified**.

4. (Applies to pages only.) Choose whether your RSS feed should display the entire page **Content**, or just the updated content (Diff).

5. Select one or more spaces from the drop-down list. Press Ctrl + left mouse button to select multiple spaces.

6. If you want to filter your RSS feed using a **label**, enter the label name in the input-field.

7. Choose the **format** for your RSS feed (if different from the default).

8. Specify the number of items you want displayed and from how far in back in time you want Confluence to look.

9. Type a **name** for your RSS feed.

10. Click 'Create RSS Feed' when you are done. This will take you to a new screen. Drag or copy the link displayed into your RSS reader.

11. To have your newsreader log into Confluence, you can add your username and password to the feed URL. But please note that if you do this, someone with access to your RSS newsreader configuration can read your password.

*Screenshot 1: RSS feed builder*
**Step 1**
Select the content you would like in this feed:
- Pages
- Comments
- News Items
- Attachments
- Mails

Sorted by:
- Created Date
- Modified Date

For Pages, Show:
- Content
- Diff

**Step 2**
Select the feed format and access:
- RSS 1.0
- RSS 2.0
- Atom

Feed size:
- Limit feed to 10 items from the last 5 days

Please choose a name for this feed:

Confluence RSS Feed

Create RSS Feed

Press Ctrl + left mouse button to select multiple spaces.

Labelled with at least one of the labels:

**Screenshot 2: Example Feed**
Removing an RSS Feed

There is no need to try to delete or remove an RSS feed built by the Confluence RSS feed builder.

Explanation: The feeds generated by the RSS Feed Builder are dynamically generated via the parameters included in the feed URL (address). For example, take a look at the following feed URL:

http://confluence.atlassian.com/createrssfeed.action?types=page&sort=modified&showContent=true...

The above feed URL will generate a list of pages ('types=page'), sorted by the modification date and showing the page content. The feed is generated at the time when the URL is fetched and there is no RSS feed information stored on the database. For that reason, there is no need to remove anything.

Watching a Page

When you watch a page, you are notified by email whenever the page is modified.

You will receive email notifications for:

- page edits (unless the "Minor change" checkbox is ticked before saving) or page deletion
- attachments (including new versions of an existing attachment or deletions of an existing attachment)
- comments (including new comments, edits of existing comments or deletions of existing comments).
Note: You will not receive notifications when page content changes simply due to the output of a macro.

For example: The output of the \{children\} macro will change if someone adds a child page. The page when displayed will show the new child page. But the page content itself has not been edited, so no notifications will be sent.

To watch a page, you require 'View' permission for the page.

To start watching a page,

1. Go to the page.
2. Click the Tools menu at the top of the page.
3. Select the 'Watch Page' icon \from the list. This will be replaced with the 'Stop Watching Page' icon \.

To stop watching a page,

1. Go to the page.
2. Click the Tools menu at the top of the page.
3. Select the 'Stop watching Page' icon \ from the list. This link will be replaced the 'Watch Page' icon \.

Here is an example of the email notification you will receive when a comment is added to a watched page:

Subject: [CONF] Confluence 2.0 User Guide: Watching a Page (comment added)
From: rcrealy@adapten.com
Date: 5:24 PM
To: vidya@adapten.com

Comment Added: CONF20: Re: Watching a Page

Watching a Page commented on by Vidya Madabushi (Nov 24, 2005).

Comment:
this is a test comment to illustrate how notifications are sent

Handy Hint
You can manage your watches via the 'Watches' tab under your user profile settings. See Managing Watches.

Watching a Space

When you watch a space, you are notified by email whenever content is added to it or updated.

To start watching a space,

1. Go to the 'Advanced' view for the space. To do this:
   * Go to a page in the space, open the 'Browse' menu and select 'Advanced'. The 'Advanced' view will open.
2. In the left-hand panel, click 'Start watching this space'. This link will be replaced with a new link to 'Stop watching this space'.

1530
To stop watching a space,

1. Go to the 'Advanced' view for the space. To do this:
   - Go to a page in the space, open the 'Browse' menu and select 'Advanced'. The 'Advanced' view will open.
2. In the left-hand panel, click 'Stop watching this space'. This link will be replaced with a new link to 'Start watching this space'.

**Handy Hint**

You can also stop watching a space via the 'Watches' tab under your user profile settings. See Managing Watches.

**Working with RSS Feeds**

An RSS feed is a format for delivering summaries of regularly changing web content. Subscribing to an RSS feed allows you to stay informed of the latest content from sites that you are interested in.

RSS isn't designed to be read in a regular web browser. Specialised RSS newsreader programs can check RSS files every so often, and tell you what's new on a site. Your reader may be on a website, an addon to your browser, part of your email program, or a stand-alone program.

Confluence works with RSS in two ways:

- Confluence generates its own RSS feeds for tracking updates to content within Confluence. You will need an RSS reader which can grab the RSS feeds from Confluence and display them for you.
- Confluence's RSS macro allows you to display the contents of RSS feeds on a Confluence page. The feeds may come from a Confluence feed generator or from external sites. In this way, Confluence can act as an RSS reader.

For a technical description of RSS, read Mark Pilgrim's "What is RSS?" article on XML.com.

**RELATED TOPICS**

- Subscribing to RSS Feeds within Confluence
- Displaying content from RSS feeds on a Confluence page
- Tracking Updates Overview

**Adding a username and password to Confluence RSS feeds**

You can create a feed from Confluence, so that you can keep track of updates to Confluence content. You will then use a feed reader to display the feed. Your feed reader may be an RSS newsreader (examples here), or you can display the feed on a Confluence page using the RSS Feed Macro.

**Adding your username and password to the feed URL**

After creating the feed, you can add your username and password to the feed URL. This will allow your feed reader to log in to Confluence. You will need to add your username and password for feed readers which use the RSS Feed Macro as well as for external RSS newsreaders.

The instructions below apply to feeds coming from Confluence. To log in to external blogs, you will need to know the specific parameters to include in the URL. The terms 'os_username' and 'os_password' are specific to Confluence.

- If you are using a newsreader, anyone with access to your RSS newsreader configuration can read your password.
- If you are embedding your feed on a Confluence page, you will include your username and password in the text of the page. Your password will be visible to anyone who can edit the page or view the source of the page.
To add a username and password to a Confluence RSS feed,

1. Get the feed URL by creating a feed from Confluence.
2. Add one of the two following strings of text to the end of the URL:
   a. ‘?os_username=myname&os_password=mypassword’ (i.e. the first character must be ‘?’ if your URL does not yet contain a parameter list starting with ‘?’)
   b. ‘&os_username=myname&os_password=mypassword’ (i.e. the first character must be ‘&’ if your URL already contains a parameter list starting with ‘?’)
      - Leave out the quotes.
      - Replace ‘myname’ with your username.
      - Replace ‘mypassword’ with your password.
      - If your username or password contain special characters, replace with URL encoding as shown below.
      - Leave the rest of the text exactly as it is.
3. Copy the URL into your newsreader or into the Confluence RSS Feed Macro.

Example:
Below is an example of a Confluence feed URL. In the example, the username is ‘Firstname Lastname’ and the password is ‘realpassword’. (Ignore the line-breaks in the example - we added them because the URL is too long to display comfortably on the page.)

```
{rss:url=http://confluence.atlassian.com/createrssfeed.action?types=page&types=comment&sort=modified&showContent=true&showDiff=true&spaces=DOC&labelString=&rssType=atom&maxResults=5&timeSpan=5&publicFeed=false&title=Example+Confluence+RSS+Feed+With+Authentication&os_authType=basic&os_username=Firstname+Lastname&os_password=realpassword,max=5|showTitlesOnly=true}
```

**URL encoding for special characters**

If you include special characters in a URL string, you must replace them with special codes, called URL encoding or percent encoding. Below are the codes for some of the most-used characters.

You can find more information here, and a URL translation function here.

<table>
<thead>
<tr>
<th>Character</th>
<th>URL encoding</th>
</tr>
</thead>
<tbody>
<tr>
<td>space</td>
<td>+</td>
</tr>
<tr>
<td>$</td>
<td>%24</td>
</tr>
<tr>
<td>&lt;</td>
<td>%3C</td>
</tr>
<tr>
<td>&gt;</td>
<td>%3E</td>
</tr>
</tbody>
</table>

**Examples:**

<table>
<thead>
<tr>
<th>Your password</th>
<th>String to include</th>
</tr>
</thead>
<tbody>
<tr>
<td>mypassword</td>
<td>&amp;os_password=mypassword</td>
</tr>
<tr>
<td>mypassword$</td>
<td>&amp;os_password=mypassword%24</td>
</tr>
<tr>
<td>mypassword$2</td>
<td>&amp;os_password=mypassword%242</td>
</tr>
</tbody>
</table>

**RSS Readers Compatibility**

Due to some users having problems with Confluence RSS Feeds, some research was done with several RSS Feed Readers. RSS Feeds have been created through the feed builder and tested on a Windows machine. For each feed reader they have been tested with both authentication and public access, checking for the visibility of content, icons and images. The results are in the tables below:

**Feeds with authentication**

<table>
<thead>
<tr>
<th>RSS Feed Reader</th>
<th>Content</th>
<th>Icons</th>
<th>Images</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>RssReader 1.0.880</td>
<td>✔</td>
<td>✔</td>
<td>✔</td>
<td>• Shows the entire page (including the header panel &amp; view, edit tabs)</td>
</tr>
<tr>
<td>Application</td>
<td>Status</td>
<td>Content Issues</td>
<td></td>
<td></td>
</tr>
<tr>
<td>------------------------------</td>
<td>--------</td>
<td>-------------------------------------------------------------------------------</td>
<td></td>
<td></td>
</tr>
<tr>
<td>JetBrains Omea Reader 2.1.6</td>
<td>✔️ ✔️ ✔️</td>
<td>Shows the changes between revisions in the nice red/green colours of Confluence</td>
<td></td>
<td></td>
</tr>
<tr>
<td>IE 7.0</td>
<td>✔️ ✔️ ✔️</td>
<td>Content is all there however not all html is rendered correctly (for example .tag {font-style:italic;} is shown in the content as raw text) Shows the changes between revisions, but without the red/green colours</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Thunderbird 1.5.0.7</td>
<td>✔️ ✔️ ✔️</td>
<td>Shows the entire page</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Bloglines</td>
<td>✔️ ✔️ ✔️</td>
<td>Simple online feed reader</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Shows the changes between revisions, but with arrows</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Google Reader</td>
<td>✔️ ✔️ ✔️</td>
<td>Simple online feed reader</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Yahoo</td>
<td>✔️ ✔️ ✔️</td>
<td>Shows the entire page</td>
<td></td>
<td></td>

**Searching Confluence**

The search box at the top right of your Confluence screen allows you to search Confluence wherever you happen to be in the site. It offers you a quick navigation aid as well as a full site search. You can also search Confluence directly from your browser's search box.

**Screenshot: The search box at the top right of a Confluence screen**

**On this page:**
- Searching Confluence from your Browser's Search Box
- Using the Quick Navigation Aid
- Performing a Full Search
- Viewing Attached Office Documents
- Accepting 'Did you mean' Suggestions from Confluence
- Filtering your Search Results
- Advanced Search Syntax
- Browsing Related Labels
- Searching the Content of Attachments

**Searching Confluence from your Browser's Search Box**

If you are using Firefox or Internet Explorer 7 or later, you can add your Confluence site as a search provider, via the dropdown menu next to the browser's search box.

**Screenshot: Adding your Confluence site to your browser's search box**
OpenSearch
Confluence supports the autodiscovery part of the OpenSearch standard, by supplying an OpenSearch description document. This is an XML file that describes the web interface provided by Confluence's search function. Any client applications that support OpenSearch will be able to add Confluence to their list of search engines. Your Confluence Administrator can enable or disable the Open Search feature via the Confluence Administration Console.

Using the Quick Navigation Aid
The quick navigation aid automatically offers a dropdown list of pages and other items, matched by title to your search query. You can select one of the offered items or ignore them altogether.

To use the quick navigation aid,

1. Start typing your query into the search box located at the top right-hand corner of every screen. Confluence matches titles as you type, showing a quickly-adjusting dropdown list of pages, news items, personal profiles, attachments and so on.
2. Press the Enter key if you want to bypass the quick navigation aid and perform a full search, as described below.
3. To see the space to which an item belongs, let your mouse pointer hover over the item in the dropdown list.
4. Use the up- and down-arrows on your keyboard to move up and down the list of matching titles and select an item.
5. Press the Enter key to open the selected item.
6. If you do not find what you are looking for, select the 'Search for' option at the bottom of the list and press the Enter key to do a full search. This has the same effect as pressing Enter immediately after typing your search query. The full search is described below.

Screenshot: The quick navigation aid showing titles matching the query 'con'
Here is more information about how the quick navigation feature works:

- Confluence will truncate any titles that are too long to be displayed.
- If a title is too long to fit the box, hover your cursor over the title to see the full text.
- The matching items are grouped by content type so that you can quickly find the type you want. Confluence shows a maximum of 6 pages and/or news items, 2 attachments, 3 people and 2 spaces. If no matches are found in a particular category, then that category does not appear in the list.
- Items are ordered with the most recent updates first.
- When the matching item is a person's name, their profile picture appears next to their name in the list.
- The part of the title that is matched by the search query is highlighted in bold text.

Your Confluence Administrator can enable or disable the quick navigation feature via the Confluence Administration Console.

### Performing a Full Search

When you perform a full search, Confluence will search all content in all spaces (global and personal), mail, personal profiles, attachments and the space description. The results will appear on a new screen.

**To use the full search,**

1. Type your query into the search box located at the top right-hand corner of every screen (or type it into the text box at the top of the Search screen).
2. Press the Enter key. (This means that you will ignore the dropdown list of titles offered by Confluence's quick navigation aid, described above.)
3. The Search screen appears, as shown below. If any Confluence pages or items match your search query, the Search screen shows a list of the matching items.
4. Click an item's title to open the Confluence page or other item.
On the left of the screen you will see a text block for each item that matched the search criteria, with the following information for each item:

- An icon representing the content type (user profile, space, page, news item, etc). See Confluence Icons.
- The title or name of the content item.
- For attachments: The size and type of file, with a link to download or view the attachment where relevant. See information on viewing Office attachments below.
- The most relevant few lines of content from within the item. Any words that match your search query are highlighted within the content.
- For personal profile items: The email address.
- The space to which the item belongs, displayed on the last line of the item's text block.
- The date when the content item was last modified.

⚠️ You will see only search results which you have permission to view.

On the right of the screen are further options which allow you to tailor or filter your search results. See below.

### Viewing Attached Office Documents

When the search results include an attached Office document, you will see a 'View' link as shown in the screen snippet below.

*Screenshot: Search results include an attached Office document with 'View' link*
Click the 'View' link to view the content of the Office document within Confluence. If you have an Office application installed, you will also be able to launch your Office editor from within Confluence. See Displaying an Office Document in Confluence and Working with the Office Connector.

**Accepting 'Did you mean' Suggestions from Confluence**

When you perform a full Confluence search, as described above, Confluence may offer you an alternative spelling of your search query. The alternative spelling will appear next to the words 'Did you mean', as shown in the example below.

**To accept an alternative spelling suggestion,**

1. Type your query into the search box.
2. Press the Enter key.
3. Confluence will analyse the wiki content, to determine whether an alternative spelling of your search query occurs more often in the wiki content. If this is the case, the words 'Did you mean' will appear on the screen, along with an alternative spelling for your search query.
4. If you want to try the alternative spelling, click the word showing the suggested spelling. In the example below, you would click the word 'confluence'.

**Screenshot : The Search screen with 'Did you mean' offering a corrected spelling**

Here is more information about how the 'Did you mean' feature works:

- Confluence uses both a dictionary (bundled with Confluence) and words mined from the content on your system to work out the best alternative spellings of your search terms. Practically, this means that Confluence can provide spelling corrections for specialised jargon that may not appear in a standard dictionary. In general, when deciding between alternative spellings, Confluence will favour words that appear more often in your content.
- In some cases, the 'Did you mean' suggestion may appear even when there are Confluence pages, etc, which match your search query. In other cases, there will be no items which match your search criteria. In both cases, Confluence will offer a 'Did you mean' suggestion if there is a word which will help you find more relevant content.
- The 'Did you mean' feature may offer more than one suggestion.
- The 'Did you mean' suggestion may even offer an incorrect spelling. This would happen if the incorrect spelling occurs many times within your Confluence site. This is intentional, because the aim of the 'Did you mean' feature is to help you find content, not to correct your spelling.

Your Confluence Administrator can enable or disable the 'Did you mean' feature via the Confluence Administration Console.

**Filtering your Search Results**

The Search screen, pictured above, appears when you do your first search. By default, Confluence will search all content across your Confluence site, including all spaces, mail archives, attachments and all other content types.

On the right of the screen are options which allow you to tailor or filter the search results.

**Screenshot : Filtering your search results**
Enter your filter criteria as described below, then click the 'Filter' button.

- **Where** — Restrict your search results to a particular space, or to your favourite spaces, global spaces or personal spaces.
- **What** — Restrict your search results to a particular content type (pages, news items, mail, etc).
- **When** — Restrict your search results to content modified within a particular period of time (today, yesterday, within the last week or within the last month).
- **Who** — Restrict your search results to content last modified by a particular user. You can start typing the person's username or part of their name into the text box as follows:
  - Type the username (e.g. 'jsmith').
  - Or start typing the person's first name (e.g. 'john')
  - Or their last name (e.g. 'smith').
  - Or another part of their name, such as a middle name.
  Confluence will offer you a list of possible matches. Use your mouse to select the person you want, then press the Enter key to filter the search results.

**Screenshot : Filtering your search results by user**

More information about the user-matching filter:
- The user-matching filter is not case sensitive. You can enter upper or lower case letters and will receive the same results.
- When looking for users to match the name you entered, Confluence divides a person's name into logical units corresponding to first name, middle name (one or more) and last name. It matches the letters of each unit in the name you entered against the letters of each unit in the user directory. For example, you can enter 'jo sm' to look for John Smith. The search is triggered after you have entered at least two letters.
- For each part of the name, you need to enter at least two letters. For example, if you enter just 'john s', the filter will look for users called 'john' and will ignore the 's'. Similarly, if you enter 'j smith' you will see everyone with the name 'smith' even if their first name does not start with a 'j'.
- You are not forced to use the auto-complete list. You can just type 'jsmith' or 'jo sm' and filter on that without choosing a match from the dropdown list. Confluence will warn you if there is more than one user corresponding to the name you have entered.

Click 'Clear Filter' if you want to remove all your filters and perform the same search again but without the filter.

**Advanced Search Syntax**

See Confluence Search Syntax for more ways to refine the text you enter into the search box.

Additionally, see Confluence Search Fields for special parameters you can use in the search box to search on various metadata.

**Browsing Related Labels**
Also on the right of the Search screen, Confluence will offer a list of labels which are related to your search query. See the screenshot above.

You can click a label to see all pages and news items tagged with that label. See Navigating Pages by Label.

**Searching the Content of Attachments**

When you search Confluence, by default the search will include the content of the following types of attachments:

- Word
- Text
- PowerPoint
- Excel
- PDF
- HTML

To search the content of other attachment types, you will need to use an attachment content extractor plugin. For more information, take a look at the following:

- Existing extractor plugins which you can install on your Confluence site.
- Guidelines on developing your own attachment content extractor plugin.

**Confluence Search Fields**

This page is intended for developers and advanced users of Confluence. It gives an overview of the Apache Lucene search fields used in Confluence.

On this page:

- Searching for Content in Specific Fields
- Confluence Search Fields
  - Personal Information
  - Pages
  - News
  - Attachments
  - Mail Items

**Searching for Content in Specific Fields**

Confluence data is stored in fields which can be specified in the search. To search a specific field, type the name of the field followed by a colon `:` and then the term you are looking for.

Examples:

```
title:"Some Title"
```

```
labelText:chalk
```

The field specification applies only to the term directly preceding the colon. For example, the query below will look for "Some" in the title field and will search for "Heading" in the default fields.

```
title:Some Heading
```

**Confluence Search Fields**
Below are the fields which can be searched, listed by content type.

### Personal Information

Confluence Search Syntax

Here’s how you can refine your search. Confluence will ignore common words like “the” unless you place your query within quotes.

**Exact phrase search**

To search for content that contains the exact phrase “chalk and cheese”

```
"chalk and cheese"
```

Confluence will ignore common words (stop words) like "and" above. This is the default list of stop words used by Lucene. Please cast your vote towards this improvement request.

For e.g:

1. Searching for “The One” returns all pages containing “One” because “The” is a stop word.
2. Searching for “Cheese One” would only return pages in which “One” appears as the first word (other than stop words) after “Cheese”. So it would return “Cheese for One” or “Cheese to One” or “Cheese One”. It would not match “One Cheese” or “Cheese Flamingo One”.

**Or Search**

To search for content that contains one of the terms, “chalk” OR “cheese”

```
chalk OR cheese
```

**And Search**

To search for content that contains both the terms “chalk” AND “cheese”

```
chalk AND cheese
```

**Not search**

To search for content that contains “chalk” but NOT “cheese”

```
chalk NOT cheese
```

**Excluded Term search**

Similar to the NOT search, to search for content that contains “chalk” and “butter” but NOT “cheese”

```
chalk butter -cheese
```

**Grouping Search**

To search for content that MUST contain “chalk” but CAN contain either “cheese” or “butter” use the search:

```
(cheese OR butter) AND chalk
```

**Title Search**

To search for content with “chalk” in its title, where title is the field keyword.

```
title:chalk
```

**Wild card searches**

**Single character**

To search for “butter” or “batter” you can use the search:

```
b?tter
```

To search for “chicken” or “chickpea” you can use the search:
Wildcards can be used anywhere within a word, except at the very beginning.
For example:

```
*chick
```

is an invalid search term.

**Multiple characters**
To search for "chick" or "chickpea".

```
c*c*
```

You can also combine search characters to get the exact word. For example the search term below will return "chick" yet not "chickpea":

```
c*c?
```

**Case Sensitivity in wildcard searches**
Since the fix for CONF-13846 Confluence is case sensitive for wildcard searches.

You should note that all the example searches given previously search across the default set of fields which are stored as lower case and therefore all searches of that style should be given lower case search terms (as shown in the examples).

However, if you were to search one of the case sensitive fields, such as "content-name-untokenized" the case of your search term would need to match the document you are searching for.

**Proximity searches**
This search ensure that the two words specified must be within a certain number of words of each other to be included.

```
"octagon post"~1
```

will return "Octagon blog post".

```
"octagon post"~0
```

is an invalid search term.

**Range search**
Searches for names that fall alphabetically within the specified range.

```
[adam to ben]
```

Note: You can't use the **AND** keyword inside this statement.

**Fuzzy search**
This search looks for words spelled similarly.
To search for octagon, if unsure about spelling:

```
oclogan~
```
will correctly return "octagon"

**Combined search**

You can also combine various search terms together:

```
?tag* AND past- AND ('blog' AND 'post')
```

Searching Confluence  
Confluence Search Fields

Take me back to Confluence User Guide

**Ranking of Search Results**

When you perform a search in Confluence, it is likely that there will be many pages or other content items that match your search terms. Confluence will rank the matching items by evaluating their relevance. This should mean that the items most relevant to you will appear at the top of the search results list, so that you can quickly select the item you need.

Below is an overview of the method Confluence uses to determine the relevance of the items returned by the search, i.e. to rank the search results.

**On this page:**
- Philosophy behind the Ranking
- Summary of the Ranking Method
- Weighting of Content Types
- Weighting of Fields
- Weighting Based on Age
- Simplified Example

**Philosophy behind the Ranking**

Confluence gives highest priority to personal information i.e. documents which take you to a user's profile when you click on them. Collaboration is a primary function of a wiki, so Confluence makes it easy to find people.

For example, if you search for 'John Smith', the first results you see will be for John Smith's user profile and personal space. There may also be other content (wiki pages, email messages, etc) which contain the words 'John Smith'. These other content types may even have 'John Smith' as the page title and repeated multiple times in the content, but they will still appear lower down in the list of search results.

Matching terms found in the title of a page, or in the title of any content type, are considered a strong match. So are matches found in labels, because when someone applies a label it means that they think the content is particularly relevant to the labelled term.

Matches found in the content body are of average importance. If the matched term appears more than once, the document will be given a proportionately higher ranking.

We also assume that information created recently is slightly more relevant than older information.

**Summary of the Ranking Method**

When displaying the results of a search, Confluence applies a weighting to each of the content items returned.

To determine the weighting:

1. For each content item, Confluence first applies three weightings based on the following:
   a. The content type of the item returned — user profile, page, news item, attachment, etc. (More details below.)
   b. The type of field in which the search term was found — title, name, label, or content body. (More details below.)
   c. The age of the item returned. (More details below.)

2. Confluence then combines the three weightings to arrive at a single weighting for the content item.

The item with the heaviest weighting will appear at the top of the list of search results, and the other items will appear below in descending order of weighting.

**Weighting of Content Types**

<table>
<thead>
<tr>
<th>Content Type</th>
<th>Weighting</th>
</tr>
</thead>
</table>
Simple example

If the search returns 7 matching items, and each item is one of the above types, then the items will be presented in the above order on the results screen. (This example assumes that the search term is found in the same field in each item — see more about fields below.)

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Weighting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Title</td>
<td>9</td>
</tr>
<tr>
<td>Full name</td>
<td>8</td>
</tr>
<tr>
<td>Label text</td>
<td>7</td>
</tr>
<tr>
<td>Content</td>
<td>5</td>
</tr>
</tbody>
</table>

Note that 'content' above could be the content of a page, or the content of a comment, or the body of any other content type. See more about content types above.

Simple example

A match for a search term in the title of a document is 1.8 times (9/5) more important than a match in the content.

Weighting Based on Age

This weighting is based on the age of the item returned in the search results. The age of the item is calculated from the creation date of the item. The age intervals are quite coarse-grained, as shown in the table below.

<table>
<thead>
<tr>
<th>When the Item was Created</th>
<th>Weighting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Today</td>
<td>1.5</td>
</tr>
<tr>
<td>Yesterday</td>
<td>1.3</td>
</tr>
<tr>
<td>Up to 1 week ago</td>
<td>1.25</td>
</tr>
<tr>
<td>Up to 1 month ago</td>
<td>1.2</td>
</tr>
<tr>
<td>Up to 3 months ago</td>
<td>1.15</td>
</tr>
<tr>
<td>Up to 6 months ago</td>
<td>1.10</td>
</tr>
<tr>
<td>Up to 1 year ago</td>
<td>1.05</td>
</tr>
<tr>
<td>Beyond a year</td>
<td>1</td>
</tr>
</tbody>
</table>

The weighting is fairly small, so will not have a large effect. When an item is more than a year old, the age weighting is just ‘1’ i.e. it has no effect.
Simple example

- If two documents match in all other ways then the newer one will be presented first.
- If the two documents being compared are both older than a year then their relative age does not matter.

Simplified Example

Let's assume you search for a single term.

Confluence finds a match in the title of an email message created today:

| Weighting for the content type (email) | 0.5 |
| Weighting for field (title)           | 9   |
| Weighting for age (today)             | 1.5 |
| **Total weighting**                   | 6.75|

Confluence also finds a match in the content of a comment created three weeks ago:

| Weighting for the content type (comment) | 5   |
| Weighting for field (content)            | 5   |
| Weighting for age (up to 1 month ago)    | 1.2 |
| **Total weighting**                      | 30  |

**Result:** The comment (weighting 30) will be appear higher in the search results than the e-mail (6.75).

Confluence uses the Apache Lucene search engine library. Lucene's score calculation has a number of additional terms, not mentioned in the above example. We have simplified above, for purposes of illustration. If you are interested, you can see more information in the Lucene documentation.

Searching the People Directory

The People Directory displays a list of people who use your Confluence site.

The People Directory includes anybody who has logged into Confluence or who has had a user account created for them in Confluence. The People Directory does not include users who can log into Confluence via external user management who have never logged in.

Viewing the People Directory

There are two ways by which you can access the people directory in Confluence:

- On the **Dashboard**, click the **People Directory** link next to the people directory icon.

- Alternatively, from most areas of Confluence, open the **Browse** menu and select **People Directory**

The Confluence administrator can hide the People Directory. If it is hidden, you will not see the 'People Directory' link either on the Dashboard or from the 'Browse' menu.
Searching for People

To search for a particular person, type their first name and/or last name into the search box and click the 'Search' button.

- To search everyone who uses your Confluence site, click the 'All People' link.
- To search just those people who have set up a personal space, click the 'People with Personal Spaces' link.
  - If a person has not yet set up their personal space, then the 'Personal Space' option will not be available from the 'More' menu of their hover profile popup. For more information about the hover profile feature, please refer to Hover Profile Overview.

Following People's Activities

Confluence's network features allow you to 'follow' (that is, keep track of) other people's activities throughout a Confluence site. For more information, please refer to Network Overview. Using the hover profile feature, the people directory is a convenient area from which you can start following other people throughout your Confluence site.

- To start following another person's activities, move your mouse over a user's name or profile picture and in their hover profile popup, click 'Follow'.
- To stop following another person's activities, move your mouse over a user's name or profile picture and in their hover profile popup, click 'Stop Following'.

Once you start following another person, their activities will start appearing in your network view.

People Directory provides hCard microformat

The People Directory uses the hCard microformat for simple integration with a variety of microformat-enabled tools. hCard is an open data format for representing people, companies, organisations, and places. Read more about microformats and hCard.

Uploading a Profile Picture

Take me back to the Confluence User Guide.

Text Tokenisation and Filtering

When searching for content based on search terms entered by the user, Confluence splits the text of the content into tokens, and then filters
and modifies those tokens according to the following rules.

**Tokenisation**

Confluence uses Lucene’s **Standard Tokenizer**. This splits the text into tokens as follows:

- Splits words at punctuation characters, removing punctuation. However, a dot that’s not followed by white space is considered part of a token.
- Splits words at hyphens, unless there’s a number in the token, in which case the whole token is interpreted as a product number and is not split.
- Recognises email addresses and internet host names as one token.

An example: The string ‘foo-bar5’ won’t be split into ‘foo’ and ‘bar5’, so a search for ‘bar5’ or ‘bar*’ will not find any results.

**Filtering**

Confluence then:

- Removes “s” from the ends of words.
- Removes the dots from acronyms, e.g. I.B.M. becomes IBM.
- Converts everything to lower case.
- Removes common words like ‘the’ and ‘or’ are removed.
- Converts words to their stems. For example, ‘fishing’ and ‘fishes’ both become ‘fish’.

Searching Confluence

**Working with Favourites Overview**

The **Favourites** feature provides a convenient way of gaining quick access to specific pages or spaces that might interest you. Pages and spaces that you have added to your list of favourites are easily accessible from your Dashboard and within your user profile area.

Adding a page or a space as a favourite provides you with faster access to the content you are interested in within the site.

1. **Favourite Spaces**

Once you add a space as a favourite, it will appear in the ‘**MY**’ tab in the spaces section of the dashboard. The ‘Recently updated’ section in this view will also display content only from your favourite spaces.

<table>
<thead>
<tr>
<th>Spaces:</th>
<th>My</th>
<th>Team</th>
<th>New (1)</th>
<th>All</th>
<th>My favourite spaces</th>
</tr>
</thead>
<tbody>
<tr>
<td>Confluence (DOC)</td>
<td><img src="image1.png" alt="Image" /></td>
<td><img src="image2.png" alt="Image" /></td>
<td><img src="image3.png" alt="Image" /></td>
<td><img src="image4.png" alt="Image" /></td>
<td><img src="image5.png" alt="Image" /></td>
</tr>
<tr>
<td>Confluence 1.4 User Guide (CONF14)</td>
<td><img src="image6.png" alt="Image" /></td>
<td><img src="image7.png" alt="Image" /></td>
<td><img src="image8.png" alt="Image" /></td>
<td><img src="image9.png" alt="Image" /></td>
<td><img src="image10.png" alt="Image" /></td>
</tr>
<tr>
<td>Confluence 2.0 User Guide (CONF20)</td>
<td><img src="image11.png" alt="Image" /></td>
<td><img src="image12.png" alt="Image" /></td>
<td><img src="image13.png" alt="Image" /></td>
<td><img src="image14.png" alt="Image" /></td>
<td><img src="image15.png" alt="Image" /></td>
</tr>
<tr>
<td>Documentation Staging (DOCPRI4)</td>
<td><img src="image16.png" alt="Image" /></td>
<td><img src="image17.png" alt="Image" /></td>
<td><img src="image18.png" alt="Image" /></td>
<td><img src="image19.png" alt="Image" /></td>
<td><img src="image20.png" alt="Image" /></td>
</tr>
<tr>
<td>Documentation Staging 2 (DOCPRI2)</td>
<td><img src="image21.png" alt="Image" /></td>
<td><img src="image22.png" alt="Image" /></td>
<td><img src="image23.png" alt="Image" /></td>
<td><img src="image24.png" alt="Image" /></td>
<td><img src="image25.png" alt="Image" /></td>
</tr>
</tbody>
</table>

The Dashboard remembers which one of the views, ‘**MY**’, ‘Team’, ‘All’ or ‘New’ you were most recently viewing. So if you clicked the ‘**MY**’ tab on this visit, next time around, as soon as you log in to Confluence, only the list of your favourite spaces and the recently modified content within them will be displayed to you.

2. **Favourite Pages**

The dashboard will display a list of your most recently added favourite pages, so you can access them easily as soon as you login to Confluence.
3. All your favourites

You can view a list of all pages and spaces you added as favourites by going to your 'Profile'. This means that you no longer have to navigate through complicated site structures to find the pages that you are interested in but can go to them directly.

### Adding Favourites

To add a page as a favourite,

1. Go to the page.
2. Click the 'Tools' menu located at the top right-hand corner of the page and choose 'Favourite'.
   This will change to 'Favourite' (when you next open the 'Tools' menu) to indicate that you have added this page as a favourite.

To add a global space as a favourite,

1. Go to the Dashboard.
2. Click on the star icon 'Favourite' located beside the space in the list of spaces displayed.
   This will change to 'Favourite' to indicate that you have added this global space as a favourite.

To add a personal space as a favourite,

- If a person has not yet created a personal space, then you will not be able to perform this procedure. Furthermore, these options will not be available to you.
1. Go to the People Directory.
2. Click on a person's name or profile picture to view their personal space.
3. Go to the 'Advanced' view for the space. To do this:
   - Go to a page in the space, open the 'Browse' menu and select 'Advanced'. The 'Advanced' view will open.
4. Click on ‘🌟 Add Space to Favourites’ in the left-hand panel.
   This will change to ‘🌟 Remove Space from Favourites’ to indicate that you have added that person's personal space as a favourite.

Once you have added a personal space to your list of favourites, that personal space will be added to your list of favourite spaces, which can be accessed from the dashboard or your profile.

For more information about global spaces and personal spaces, see Working with Spaces Overview.

**RELATED TOPICS**

Viewing Favourites

Take me back to the Confluence User Guide.

**Removing Favourites**

To remove a page as a favourite,

1. Go to the page.
2. Click the 'Tools' menu located at the top right-hand corner of the page and choose ‘🌟 Favourite’.
   This will change to ‘🌟 Favourite’ to indicate that you have removed this page from your favourites.

To remove a global space as a favourite,

1. Go to the dashboard.
2. Click on the star icon ‘🌟’ located beside the space in the list of spaces displayed.
   This will change to ‘🌟’ to indicate that you have removed this global space as a favourite.

To remove a personal space as a favourite,

1. Go to the People Directory.
2. Click on a person's name or profile picture to view their personal space.
3. Go to the 'Advanced' view for the space. To do this:
   - Go to a page in the space, open the 'Browse' menu and select ‘Advanced’. The 'Advanced' view will open.
4. Click on ‘🌟 Remove Space from Favourites’ in the left-hand panel.
   This will change to ‘🌟 Add Space to Favourites’ to indicate that you have removed that person's personal space as a favourite.

**User Profile Overview**

Each Confluence user has a User Profile area, through which numerous account management features can be accessed.

**On this page:**

- Finding your User Profile
- Profile
- Network
- Status Updates
- Labels
- Watches
- Drafts
- Settings

**Finding your User Profile**

Go to the 'Profile' view for your user profile. To do this:

- Log in to Confluence, if you have not already done so.
- Go to your name at the top of the page. (This is the 'User' menu. A dropdown list will appear when your cursor hovers over the 'User' menu.)
- Select 'Profile' from the dropdown list. The 'Profile' view will open.

The profile view is divided into the tabs, each described in a separate section below.

*Screenshot: User profile*
The 'Administer User' link is visible to Confluence administrators only. The administrator can click this link to go directly to the user management screen in the Administration Console.

Profile

- View and edit your personal details, such as your name and email address details and optionally, your photograph and other personal information.
- Upload a profile picture (optional).
- Change your password.

Network

- View the recent activity of users that you are following via the Network view.
- Follow other users from this view.

Status Updates

- View your history of status updates.

Labels

- View your personal labels.

Watches

- View a list of the pages and spaces you are currently watching.

Drafts

- Retrieve any pages you were in the process of editing. See Working with Drafts.

Settings
• Edit your General Settings (homepage, language and timezone).
• Subscribe to email notifications and modify other email notification preferences.

   • Go to your name at the top of the page. (This is the 'User' menu. A dropdown list will appear when your cursor hovers over the 'User' menu.)
   • Select 'Profile' from the dropdown list. The 'Profile' view will open.
2. On your 'Profile' tab, click the 'Password' link in the left-hand column.
3. Enter your current password and your new password in the form displayed.
4. Click 'Submit' to save your changes.

Editing User Settings

You can customise Confluence by choosing your Confluence settings and preferences — home page, language and time zone.

To edit your User Profile Settings,

1. Go to the 'Profile' view for your user profile. To do this:
   • Log in to Confluence, if you have not already done so.
   • Go to your name at the top of the page. (This is the 'User' menu. A dropdown list will appear when your cursor hovers over the 'User' menu.)
   • Select 'Profile' from the dropdown list. The 'Profile' view will open.
2. Click the 'Settings' tab.
3. Click the 'Edit' button.
4. Choose your General Settings in the form that is displayed:
   • Site Homepage — choose the page that you would like to see whenever you log into Confluence.
   • Language — choose your language.
   • Time zone — choose your time zone.
5. Click the 'Submit' button.

Screenshot: Editing your User Profile Settings
Editing User Profile

Your user profile contains basic information about you. If you do not have a personal space, your user profile will be displayed when anyone clicks your name in the People Directory.

To edit your user profile,

1. Go to the 'Profile' view for your user profile. To do this:
   - Log in to Confluence, if you have not already done so.
   - Go to your name at the top of the page. (This is the 'User' menu. A dropdown list will appear when your cursor hovers over the 'User' menu.)
   - Select 'Profile' from the dropdown list. The 'Profile' view will open.
2. On your Profile view, click 'Edit' in the Personal details section.
3. Enter details about yourself in the form displayed.
   - **Full Name** - enter your name as you would like it to appear in your profile.
   - **Email** - specify your email address which will be used to send you mail notifications.
   - **Phone** - enter your phone number.
   - **IM** - enter your Instant Messenger (IM) details.
     - To suit a variety of IM applications, this option accepts any 'string' value. For example, you can enter IM details in the form of an email address, such as 'name@chat.example-company.com' or a user ID, like '123456789'.
   - **Website** - enter your website's URL.
   - **Position** - enter the title of your position within your organisation.
   - **Department** - enter the name of your department within your organisation.
   - **Location** - enter the name of your location. This could be anything from a town or city to a region or country.
   - **About me** - Enter information about yourself that other users can view (such as your professional information, hobbies, and other interests). You can use Confluence markup in this field.
4. Click 'Save' to record your changes.

Screenshot: Edit profile
Handy Hint
Confluence administrators can configure Confluence to mask email addresses (e.g. 'example at atlassian dot com'), protecting your email address from search engine spiders and the like.

Viewing Status Updates

A Confluence user's Status Updates view shows a history of updates they have made to their User Status message. This includes their current User Status and any previous Status Update messages, which they have retained.

Any user's current User Status message is shown on their:

1. Profile view
2. Profile Sidebar
3. Hover Profile pop-ups
A user can clear their current User Status message at any time and when they do, it will be removed from these three areas.

On this page:

- Accessing Your Status Updates View
- Clearing Your Current Status
- Deleting a Status Update

Accessing Your Status Updates View

To access your Status Updates view,

- Go to the 'Status Updates' view for your user profile. To do this:
  - Log in to Confluence, if you have not already done so.
  - Go to your name at the top of the page. (This is the 'User' menu. A dropdown list will appear when your cursor hovers over the 'User' menu.)
  - Select 'Status Updates' from the dropdown list. The 'Status Updates' view will open.

Clearing Your Current Status

You can clear your current User Status message either via your Status Updates view or your User Profile view.

To clear your current User Status message via your Status Updates view,

1. Go to the 'Status Updates' view for your user profile. Refer to Accessing Your Status Updates view (above) for this procedure.
2. Click 'Clear' in the top message. Your User Profile view will be displayed and the current User Status message cleared.

To clear your current User Status message via your Profile view,
1. Go to the ‘Profile’ view for your user profile. To do this:
   - Log in to Confluence, if you have not already done so.
   - Go to your name at the top of the page. (This is the ‘User’ menu. A dropdown list will appear when your cursor hovers over the ‘User’ menu.)
   - Select ‘Profile’ from the dropdown list. The ‘Profile’ view will open.
2. Click ‘Clear’ in your current User Status message at the top of the page. Your User Profile view will be refreshed and the current User Status message cleared.

Deleting a Status Update

To delete your current or a previous User Status message,

1. Go to the ‘Status Updates’ view for your user profile. Refer to Accessing Your Status Updates view (above) for this procedure.
2. Click ‘Delete’ next to the appropriate User Status message. Your Status Updates view will be refreshed and the message you deleted removed from the list.

Email Address Privacy

Confluence can mask the email addresses of users to protect them from mail spammers.

This is done by a Confluence administrator and is configured through the Administration Console. The Confluence administrator has three options for email address privacy:

- **Public**: email addresses are displayed publicly.
- **Masked**: email addresses are still displayed publicly, but masked in such a way to make it harder for spam-bots to harvest them.
- **Private**: only Confluence administrators can see the email addresses.

For more information on setting these options, which are configured via the Administration Console, refer to User Email Visibility.

User Email Visibility

Updating Email Address

The email address you specify in your profile settings is used for your mail notifications and is also displayed in your profile description.

To update your email address,

1. Go to the ‘Profile’ view for your user profile. To do this:
   - Log in to Confluence, if you have not already done so.
   - Go to your name at the top of the page. (This is the ‘User’ menu. A dropdown list will appear when your cursor hovers over the ‘User’ menu.)
   - Select ‘Profile’ from the dropdown list. The ‘Profile’ view will open.
2. While on the ‘Profile’ tab, click ‘Edit’ in the Personal details section.
3. In the Email field, specify your new email address which will be used when sending you mail notifications.
4. Click ‘Save’ to save your changes.
Uploading a Profile Picture

Your profile picture is used as the icon for your personal space, to represent you in the People Directory, and to illustrate your comments. You may upload your own profile picture, or use one of the images provided by Confluence. If you upload your own profile picture, you will have an opportunity to crop the picture in-line.

Please note that the final image will always be limited to 48x48 pixels.

To upload a profile picture,

1. Go to the 'Profile' view for your user profile. To do this:
   * Log in to Confluence, if you have not already done so.
   * Go to your name at the top of the page. (This is the 'User' menu. A dropdown list will appear when your cursor hovers over the 'User' menu.)
   * Select 'Profile' from the dropdown list. The 'Profile' view will open.
2. On your 'Profile' view, click the 'Picture' link in the left-hand column.
3. Either:
   a. Click the 'Browse' button to locate your picture file, then click the 'Upload' button to upload it from your computer or file server.
   b. Alternatively, you can select one of the default icons provided.
4. Click the 'Set Profile Picture' button.

If the picture is much larger than 48x48 pixels, the 'Edit My Profile Picture' screen appears.
To edit your profile picture,

This screen is automatically loaded when your uploaded profile picture is larger than 48x48 pixels.

1. Click and drag the centre of the superimposed square to select the centre of the new image.
2. Click the corners of the square to re-size the area for your new image.
3. Click the ‘Save’ button.
4. The image from your selected area will be cropped, re-sized to 48x48 pixels and saved.

Screenshot: Resizing a Profile Picture
Deleting a Profile Picture

You can delete the profile picture images that you have uploaded to Confluence.

To delete a profile picture,

1. Go to the 'Profile' view for your user profile. To do this:
   - Log in to Confluence, if you have not already done so.
   - Go to your name at the top of the page. (This is the 'User' menu. A dropdown list will appear when your cursor hovers over the 'User' menu.)
   - Select 'Profile' from the dropdown list. The 'Profile' view will open.
2. While on the 'Profile' tab, click the 'Picture' link in the left-hand column.
3. Locate the picture file you wish to delete, select it, then click the 'Delete' button to remove it from the Confluence server.
   Note that you can only delete images that you have uploaded to Confluence. The standard icons cannot be deleted.
4. You will be prompted to confirm the action, with the following message:
   "Do you really want to delete this profile picture? This action can not be un-done."
   Click Delete.
5. The picture is permanently removed from the server.
Viewing User Profile

A Confluence User's Profile view shows details about that person and lists their recent activity. If you are viewing your own Profile view, you can also update your profile picture and login password. If you are viewing another user's Profile view, you can add them to your Network of users you are following and if they have set up a Personal Space, you can add this to your list of Favourites.

To access your User Profile view,
Go to the 'Profile' view for your user profile. To do this:

- Log in to Confluence, if you have not already done so.
- Go to your name at the top of the page. (This is the 'User' menu. A dropdown list will appear when your cursor hovers over the 'User' menu.)
- Select 'Profile' from the dropdown list. The 'Profile' view will open.

Screenshot: User Profile View

Updating your Profile

You can update the following aspects of your Profile from this view:

- **Information about yourself** - to modify these details, see Editing User Profile.
- **Your Profile picture** - to change your Profile picture or upload a new one, see Uploading a Profile Picture.
- **Your login password** - to change your login password, see Changing Password.

You can switch between your Profile, Profile picture update and login password update views by clicking the 'Details', 'Picture' and 'Password' links in the left-hand column, respectively.

Editing User Profile
Managing Watches

Take me back to the Confluence User Guide.

**User Status Overview**

The **User Status** feature allows any Confluence user to broadcast short message rapidly, which other users can observe on various activity streams throughout Confluence. These short messages could include:
• A description about what you are working on
• A question you may want answered quickly
• A hyperlink that you share immediately with other users
• Any other message you may want to share quickly with other users

There are numerous activity streams throughout Confluence that show different types of User Status updates. These include:

• The Recently Updated list on the Confluence Dashboard, which shows all status updates (when the 'All' tab is selected).
• Your Network page, which shows the status updates of Confluence users you are following.
• The Network page of Confluence users who are following you, which shows your status updates.
• The Recently Updated and Recently Updated Dashboard macros, which shows all status updates (provided that these macros’ space parameters have been set to '@all').
• Any Confluence user's Activity section of their Profile Sidebar, which is available on all pages within their personal space and shows their status updates.

While activity streams show recent User Status updates, they may soon disappear from the end of the list as subsequent user activity items appear on these streams. However, you can view any Confluence user's current User Status message in the following areas:

• Their Hover Profile.
• The Profile section of their Profile Sidebar, which is available on all pages within their personal space.
• Their Profile page.

You can also view any Confluence user's entire history of User Status updates in their Status Updates page.

Setting or Updating Your User Status

To set or update your User Status,

1. Log in to Confluence, if you have not already done so.
2. Go to your name at the top of the page. (This is the 'User' menu. A dropdown list will appear when your cursor hovers over the 'User' menu.)
3. Select 'Update Status' from the dropdown list. The 'What are you working on?' window will open.
4. Enter a short message that encapsulates your current status or what you are working on. Status messages are limited to 140 characters. If you exceed this limit, you will not be able to update your status.
5. Click the 'Update' button and your new or updated User Status will be recorded on the activity streams (mentioned above), your Personal Space Sidebar, your Profile page and your Status Updates page.

Clearing Your Current User Status

You can clear your Current User Status either via your Profile or Status Updates views.

1. To clear your current User Status via your Profile view,

   1. Go to the 'Profile' view for your user profile. To do this:
      • Log in to Confluence, if you have not already done so.
      • Go to your name at the top of the page. (This is the 'User' menu. A dropdown list will appear when your cursor hovers over the 'User' menu.)
      • Select 'Profile' from the dropdown list. The 'Profile' view will open.
   2. In the current User Status message at the top of the page, click 'Clear' and your current User Status is cleared.
To clear your current User Status via your Status Updates,

1. Go to the ‘Status Updates’ view for your user profile. To do this:
   - Log in to Confluence, if you have not already done so.
   - Go to your name at the top of the page. (This is the ‘User’ menu. A dropdown list will appear when your cursor hovers over the ‘User’ menu.)
   - Select ‘Status Updates’ from the dropdown list. The ‘Status Updates’ view will open.
2. In the current User Status message at the top of the page, click ‘Clear’ and your current User Status is cleared.

### Network Overview

The network feature helps you keep track of what other users are doing throughout your Confluence site, by allowing you to ‘follow’ their recent activities. Unlike Confluence’s traditional content tracking features, which provide notifications on specified types of content updates made by any user, the network feature provides notifications on updates made by specific users that you choose to follow. The types of activities tracked by the network feature, include:
To start tracking another Confluence user's activities, you need to 'follow' them. Once you are following a user, all their tracked activities that you have permission to view will appear on your network view. This principle applies to all users throughout your Confluence site. Hence, if other users start following you, all your Confluence-based activities that they have permission to view will appear on their network views.

You can also subscribe to any Confluence user's network RSS feed and receive summaries on the activities of other users they are following in their network. Refer to Subscribing to a Network RSS Feed for more information on setting up a network RSS feed.

**Accessing Your Network View**

To access your network view,

- Go to the 'Network' view for your user profile. To do this:
  - Log in to Confluence, if you have not already done so.
  - Go to your name at the top of the page. (This is the 'User' menu. A dropdown list will appear when your cursor hovers over the 'User' menu.)
  - Select 'Network' from the dropdown list. The 'Network' view will open.

You can access your 'Network' view by clicking the More link in the Network section of your 'Profile Sidebar'.

You can access other user's network views via the 'hover profile' feature or from their 'profile sidebar'.

**Following Another User**

You can follow another user either via the hover profile feature, your Network view or via their Profile view.

To follow a user via the hover profile feature,
To follow a user via your network view,

1. Go to the network view for your user profile. Refer to Accessing Your Network View (above) for this procedure.
2. In the right-hand section of the page within the 'Following' section, enter the first few characters of any part of the full name or username of the user you wish to follow.
   Use Confluence's 'user picker' popup to select the appropriate user.
3. Click the 'Follow' button and you will start following this user.
   Repeat this procedure for any other users you wish to follow.
   If you refresh your Network view or subsequently revisit it, the profile picture(s) of the user(s) you just followed will appear within the 'Following' list on the right. Additionally, their tracked activities will start appearing in the 'Recent Activity' list on this page.

To follow a user via their profile view,

1. Go to the 'Profile' view of the relevant user profile. To do this:
   - Log in to Confluence, if you have not already done so.
   - Use the 'Hover Profile' feature or the 'Profile Sidebar' of the user whose 'Profile' view you wish to access.
     The user's 'Profile' view will open.
2. In the left-hand section of the page, click 'Follow' and you will start following this user.
   Repeat this procedure for any other users you wish to stop following. However, you may find this process easier using the Hover Profile feature.
   If you refresh or revisit your network view, the profile picture(s) of the user(s) you just followed will appear within the 'Following' list on the right. Additionally, their tracked activities will start appearing in the 'Recent Activity' list on this page.

Stop Following a User

You can stop following a user either via the hover profile feature or via their Profile view.

To stop following a user via the hover profile feature,

1. Open the user's 'hover profile' popup. To do this:
   - Log in to Confluence, if you have not already done so.
   - Move your mouse pointer over a user's linked name, which appears on the dashboard, a page or blog post.
     Wait until the hover profile popup appears on the page.
     The hover profile popup also appears whenever you move your mouse pointer over a user's profile picture throughout the Confluence interface.
2. Within the hover profile popup, click 'Stop Following' and you will stop following this user.
   Repeat this procedure for any other users you wish to stop following.
   If you refresh or revisit your network view, the profile picture(s) of the user(s) you just stopped following are removed from the 'Following' list on the right. Additionally, their tracked activities will stop appearing in the 'Recent Activity' list on this page.

To stop following a user via their Profile view,
1. Go to the 'Profile' view of the relevant user profile. To do this:
   - Log in to Confluence, if you have not already done so.
   - Use the 'Hover Profile' feature or the 'Profile Sidebar' of the user whose 'Profile' view you wish to access.
     The user's 'Profile' view will open.
2. In the left-hand section of the page, click 'Stop Following' and you will stop following this user.
   - Repeat this procedure for any other users you wish to stop following. However, you may find this process easier using the hover profile feature.
   - If you refresh or revisit your network view, the profile picture(s) of the user(s) you just stopped following are removed from the 'Following' list on the right. Additionally, their tracked activities will stop appearing in the 'Recent Activity' list on this page.

RELATED TOPICS
Network Macro
Hover Profile Overview
Subscribing to a Network RSS Feed

Subscribing to a Network RSS Feed
You can create an RSS Feed from any user's network view, allowing you to receive summaries on the activities of users they are following in their network. The types of activities tracked in these RSS feed summaries include:
   - Additions or edits to pages or blog posts
   - Comments added to a page or blog post or edits to existing comments
   - Updates to a user's User Status
   - Updates to a user's User Profile

To subscribe to a user's network RSS feed,

1. Locate the following icon which is available from the top-right of:
   - The 'Recent activity of the users you are following' section of your network page, or
   - The 'Activity of followed users' section of another user's network page.
2. Copy and paste the icon's link into your RSS newsreader.
3. To have your newsreader log into Confluence, you can add your username and password to the feed URL.
   - Please note that if you do this, someone with access to your RSS newsreader configuration can read these Confluence authentication details.

Customising your Network RSS Feed
Currently, Confluence does not provide a user interface mechanism for customising your network RSS feed. However, you can modify the maximum number of results and type of content displayed in these feeds by directly editing the RSS feed link in your RSS newsreader.

To modify the maximum number of results displayed in your RSS feed,

1. Edit the RSS feed link in your RSS newsreader.
2. Change the value of the max parameter from its default value of 40 to a value of your choice. The following example shows this parameter-value combination highlighted in red:
   http://confluence.atlassian.com/feeds/network.action?username=ggaskell&max=60&publicFeed=false&os_authType=basic&rssType=atom
3. Save the modified link in your RSS newsreader.

To modify the type of content displayed in your RSS feed,
1. Edit the RSS feed link in your RSS newsreader.
2. Append the parameter `contentType` to the end of the link, followed by an equals sign (\(=\)) and then add the appropriate content type value of your choice:
   - `USER_STATUS` — restricts the RSS feed to user status updates.
   - `PAGE` — restricts the RSS feed to page additions or updates.
   - `BLOG` — restricts the RSS feed to blog post additions or updates.
   - `ATTACHMENT` — restricts the RSS feed to attachment additions or updates.
   - `COMMENT` — restricts the RSS feed to comment additions or updates.

   Content type values are case-sensitive and when editing the network RSS feed link, ensure that each parameter is separated from the other by an ampersand (\&).

   The following example shows the content type parameter-value combination highlighted in red:
   
   `http://confluence.atlassian.com/feeds/network.action?username=ggaskell&max=40&publicFeed=false&os_authType=basic&rssType=atom&contentType=USER_STATUS`

3. Save the modified link in your RSS newsreader.

   Filtering for more than one type of content (by adding multiple values to the `contentType` parameter) is not supported.

Network Overview
Subscribing to RSS Feeds within Confluence

Take me back to the Confluence User Guide.

**Hover Profile Overview**

Hover Profile is a convenient tool that provides quick access to key information about other Confluence users, their User Profile features and Network functions, throughout the Confluence interface. When you move or hover your mouse over a user's name, an interactive popup balloon appears, providing you with immediate access to these features and functions.

On this page:
- Using Hover Profile
  - Hover Profile Layout
  - Accessing a Hover Profile
- Using the Hover Profile Popup Balloon

**Using Hover Profile**

Whenever you hover your mouse pointer over a user's name appearing on the Confluence interface, their hover profile popup balloon appears.

*Screenshot: Using Hover Profile*
Hover Profile Layout

The top section of the hover profile popup balloon shows the user's Full Name, Profile Picture and Email address, based on their current User Profile details. Beneath this is shown the user's current User Status message. The low edge of the hover profile popup balloon has interactive features, described below in Using the Hover Profile popup balloon.

Accessing a Hover Profile

Areas of the Confluence interface where hover profile popup balloons are accessible include:

- The Byline of a page or blog
- The People Directory
- The outputs of various Confluence Macros on a page or blog
- Page or blog edit histories or comparisons
- Page or blog information pages

Hover profile is not available in the administrative areas of Confluence, such as the user management features of the Administration Console.

Using the Hover Profile Popup Balloon

From a user’s hover profile popup balloon, you can easily:

- send an email to them,
- access their personal space (if they have one),
- access their profile, network or status updates views, or
- follow or stop following them. Please refer to the Network Overview page for details on using Confluence’s network features.

To email a user from their hover profile popup balloon,

1. Hover your mouse over the user’s name on the Confluence interface until their hover profile popup balloon appears.
2. Move your mouse directly into the popup balloon and click on the user’s email address. Your email client opens up a new message with that email address in the ‘To’ field.

To access a user’s personal space from their hover profile popup balloon,

1. Hover your mouse over the user’s name on the Confluence interface until their hover profile popup balloon appears.
2. Move your mouse directly into the popup balloon’s ‘More’ menu and click the Personal Space item. The user’s personal space page will be displayed.
   If the user does not have a personal space, then this item will not be available from the ‘More’ menu.

To access a user’s profile, network or status updates views from their hover profile popup balloon,
Customising Look and Feel

Confluence allows you to customise the 'look and feel' of an individual space on the Confluence instance through options available in the Space Administration menu. By default, the look and feel of a space is based on global settings configured from the Administration Console.

You need to be a space administrator to edit the look and feel of a space.

- Applying A Theme To A Space
- Change Confluence Browser Icon
- Changing a Space's Logo
- Customising Homepage
- Editing a Space's Colour Scheme
- Modifying Confluence Layouts Using Custom Decorators

RELATED TOPICS

Browsing a space
Administrator's Guide - Design and Layout

Take me back to Confluence User Guide

Applying A Theme To A Space

Themes allow you to personalise the 'look and feel' of Confluence. Themes can can be applied across Confluence or to individual spaces. Use themes if you want to add a new functionality or significantly alter the appearance of Confluence.

Themes are created and installed from the Administration Console by site administrators. Once a theme has been installed, a space administrator can then apply it to the space.

By default, no themes are applied and the look and feel of a space conforms to global look and feel settings.

To apply a theme to a space,

1. Go to the 'Space Admin' tab of the Browse Space view. To do this:
   - Go to a page in the space, open the 'Browse' menu and select 'Space Admin'. The 'Space Administration' view will open.
     - 'Space Admin' is only displayed if you are a space administrator.

2. Now click 'Themes' in the left panel under the heading 'Look and Feel'. This will bring up a new screen. Any themes installed will be listed here. See screenshot below.
3. Click a radio button to select a theme.
4. Click 'Confirm'.

Screenshot : Applying a theme
Change Confluence Browser Icon

The Confluence logo is displayed in the user's browser to identify the Confluence browser tab. To use a custom image for your Confluence site:

1. Obtain or create an image in PNG file format. To maximise browser compatibility, it should be 32x32 pixels, 71x71 DPI and have 8 bit colour depth.
2. In your Confluence install, find the subdirectory
3. Backup the file favicon.png
4. Replace the favicon.png with your custom PNG image
5. Restart your application server

Users may need to clear their browser cache to view the new image.

To create an ICO out of your PNG image, you can use the freeware tool png2ico.

Changing a Space's Logo

In Confluence, you can replace the default logo for a space with a logo of your own choice.
You need to be a space administrator to replace a space's logo.

The instructions below refer to global spaces. For your personal space, your profile picture is used as the space icon.

To change a space's logo,

1. Go to the 'Space Admin' tab of the Browse Space view. To do this:
   - Go to a page in the space, open the 'Browse' menu and select 'Space Admin'. The 'Space Administration' view will open.
   
   * 'Space Admin' is only displayed if you are a space administrator.

2. Click on 'Change Space Logo' in the left panel under the heading 'Look and Feel'. This will bring up a new screen. See screenshot below.

3. Use the browse option to locate the new logo and click 'Upload'.

Screenshot: Change space's logo

Change the logo for this space.

RELATED TOPICS

Customising Look and Feel

Customising Homepage

Registered users of the site can choose the page to which they are directed after they log in to Confluence. By default, users are directed to the Dashboard after logging in.

To set the site home page,

1. Open the 'General Preferences' view. The page Navigating to the General Preferences View does not exist.
2. Click the 'Edit Profile' tab.
3. Click 'General', under 'Preferences' on the left navigation bar.
4. From the drop-down menu beside Site Homepage, select a space. Note that only the list of spaces to which you have 'view' access is displayed here. Selecting a space will direct you to its home page when you log in.
5. Click 'Save'.

Screenshot: General Preferences Settings
Editing a Space's Colour Scheme

Confluence allows you to customise the colour scheme of a space. By default, a space's colour scheme is based on global settings configured from the Administration Console.

You need to be a space administrator to edit a space's colour scheme.

To change the colour scheme for a space,

1. Go to the 'Space Admin' tab of the Browse Space view. To do this:
   - Go to a page in the space, open the 'Browse' menu and select 'Space Admin'. The 'Space Administration' view will open.
   - 'Space Admin' is only displayed if you are a space administrator.

2. Click 'Colour Scheme' in the left-hand panel under the heading 'Look and Feel'. This will bring up a new screen.
3. Click the 'Select' button next to a colour scheme under 'Custom Colour Scheme' (if not already selected).
4. Click the 'Edit' link. This will bring up a new screen. See screenshot below.
5. Enter standard HTML/CSS2 colour codes, or use the colour-picker to choose a new colour from the palette provided. Any changes you make will immediately be reflected in this space.

The colour scheme applies to the following UI elements:

- Top Bar - the bar across the top of the page that contains the breadcrumbs
- Tab Navigation Background - the background colour of the tab navigation menus
- Tab Navigation Text - the text of the tab navigation menus
- Breadcrumbs Text - the breadcrumbs text in the top bar of the page
- Space Name Text - the text of the current space name located above the page title
- Heading Text - all heading tags throughout the space
- Links - all links throughout the space
- Borders and Dividers - table borders and dividing lines
- Tab Navigation Background Highlight - the background colour of the tab navigation menu when highlighted
- Tab Navigation Text Highlight - the text of the tab navigation menu when highlighted
- Top Bar Menu Selected Background - the background colour of the top bar drop down menu when selected
- Top Bar Menu Item - the text colour of the menu items in the top bar drop down menu
- Page Menu Selected Background - the background colour of the drop down page menu when selected
- Page Menu Item Text - the text of the menu items in the drop down page menu
- Menu Item Selected Background - the background colour of the menu item when selected (applies to both the top bar and page drop down menus)
- Menu Item Selected Text - the text colour of the menu item when selected (applies to both the top bar and page drop down menus)
Please note that some UI elements are specific to the default theme and may not take effect for other themes.

Customising Look and Feel

Take me back to Confluence User Guide

**Modifying Confluence Layouts Using Custom Decorators**

If you modify the look and feel of Confluence by following these instructions, you will need to update your customisations when upgrading Confluence. The more dramatic the customisations are, the harder it will be to reapply your changes when upgrading. Please take this into account before proceeding with your customisation.

Confluence is built on top of the Open Source SiteMesh library, a web-page layout system that provides a consistent look and feel across a site. SiteMesh works through ‘decorators’ that define a page’s layout and structure.

To edit the layout of Confluence, you will need to modify these decorator files. A decorator file is a vmd file and is written in a very simple programming language called Velocity. Learn more about Velocity. Once you become familiar with Velocity, you can edit the decorator files to personalise the appearance of Confluence.

You need to have System Administrator permissions in order to perform this function.
You can customise the layouts for a particular space or for the whole site. This page tells you how to customise layouts for a space. To customise the global layouts, use the 'Layout' menu on the 'Administration' page.

When you upgrade Confluence, you must reapply your custom layouts to the new default layouts.

These files are grouped into:

**Site layouts**: These are used to define the controls that surround each page in the site. For example, if you want to make changes to the header and the footer, you will need to modify these layouts.

**Content layouts**: These control the appearance of content such as pages and news items: they don't change the way the pages themselves are displayed, but they allow you to alter the way the surrounding comments or attachments are shown.

**Export Layouts**: These control the appearance of spaces and pages when they are exported to HTML. If you are using Confluence to generate a static website, for example, you will need to modify these layouts.

Learn more about using decorators.

**To edit a decorator file,**

1. Go to the 'Space Admin' tab of the Browse Space view. To do this:
   - Go to a page in the space, open the 'Browse' menu and select 'Space Admin'. The 'Space Administration' view will open.
   - 'Space Admin' is only displayed if you are a space administrator.

2. Click the 'Layout' link in the left panel under the heading 'Look and Feel'. A list of the layouts for the space is listed.
   - Click 'View Default' to view the vmd file.
   - Click 'Create Custom' to edit the default vmd file. This will open up the vmd file in edit mode. Make changes and click 'Update'.

### Screenshot: Edit Layouts Example

Take me back to Confluence User Guide

**Working with Templates Overview**

Whenever you add a new page you do not have to prepare it from scratch. Instead, you can base your new page on a template, which is essentially a page with pre-populated content.
Templates may be written in regular Confluence markup, or using special markup if you wish to define form fields to be filled in.

Some examples:

- A software development project may have a template for use-cases.
- A systems administration space may have a template for defining what information is kept about each server.

In Confluence, there are two places to store your templates:

- **Global Templates**: These are defined by site administrators through the Administration Console and are available in every space.
- **Space Templates**: These are defined by space administrators in the space administration screens, and are only available in the space in which they are defined.

Global templates can only be created by site administrators, and space templates by space administrators.

Here is an example:

**Step 2: Fill in template variables**

Choose values for the variables in this template. These values will be automatically inserted into the template for you in the correct locations.

```
This is a template about [Thing]

Name: [Name]
Phone Number: [PhoneNumber]
Date of Birth: [DOB]
```

**Note**

Currently, templates can only be used to create a page. Once a page is created, the template is gone and all further editing is performed as if the template was never used. Some plugins provide expanded functionality for strictly templated content. See below for more information.

**Important Plugins For Templates**

Two popular plugins that expand on template behaviour are the Zones Plugin and Scaffolding Plugin. Below is a comparison:

<table>
<thead>
<tr>
<th>Field</th>
<th>Default</th>
<th>Zones Plugin</th>
<th>Scaffolding Plugin</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td>Basic</td>
<td>Flexible</td>
<td>Powerful</td>
</tr>
<tr>
<td>Saves page version history</td>
<td>✔️</td>
<td>✔️</td>
<td>✔️</td>
</tr>
<tr>
<td>Allows return to form version</td>
<td>❌</td>
<td>✔️</td>
<td>✔️</td>
</tr>
<tr>
<td>Suitable for dynamic data</td>
<td>❌</td>
<td>✔️</td>
<td>✔️</td>
</tr>
<tr>
<td>Has a library of examples</td>
<td>❌</td>
<td>❌</td>
<td>✔️</td>
</tr>
</tbody>
</table>

**RELATED TOPICS**
Adding a Template

You need to be a space administrator to create a space template.

To add a template for a space,

1. Click the 'Browse Space' link for the space. This is located at the top of every page and beside the space link on the dashboard.
2. Go to the 'Advanced' tab then click the 'Templates' option in the left navigation panel.
3. Click 'Add New Space Template'. This will bring up the 'Create Template' screen.
4. Enter a name for your template in the 'Name' text field and an optional description in the 'Description' text field.
5. Using regular Confluence markup and form field markup (if you are using forms), enter content in the text-entry box as you would in any other Confluence page. For example:

   ```
   h3. Client Information Form - *@$CLINFO*$
   | Type | @TYPE|list(Organisation, Individual)| |
   | Contact Person | @NAME| |
   | Contact Email | @EMAIL| |
   | Contact Phone | @PHONE| |
   | Origin | @COUNTRY|list(America, Africa, Asia, Europe,)| |
   | Site | @SITE| |
   | Notes | @DESCRIPTION|textarea(5x20)| |
   ```

6. Click 'edit' next to 'Labels' if you want to use labels to categorise information. Add your labels. These labels will be included in all pages created using this template.
7. Preview and click 'Save'. Your template will be added to the list of space templates.
8. To view the space templates, browse the space then click the 'Templates' option in the left navigation panel of the 'Advanced' tab.

For more information, check out this example template.

Working with Pages

Take me back to Confluence User Guide
Confluence allows you to create a page based on a global template (available to all spaces) or a space template (available only to that space). This page is intended for users who have already created a template.

Labels are copied from template

If the template contains labels, the template labels will automatically be included in the new page created from that template.

To create a page from an existing template

1. Click the 'Add Page' link located beside each space on the dashboard or at the top of every page in Confluence.
2. Click the link 'Select a page template' located above the text-entry box. This is only displayed if there are any templates defined. If you do not see this link, then there are currently no templates defined and an administrator will have to create one before you can use it.
   
   Clicking this link will display a list of the templates that are available in the current space.
3. Select a template and click 'Next'. This will display one of the following:
   - A new page based on the template, if the template does not contain a form.
   - The 'Template Variables' page where you can supply values for the variables, if the template contains a form.
4. If the template uses a form, enter the appropriate values into the form fields and click the 'Insert Variables' button. This will display a new page based on the template and including the variable values you have entered.
5. Replace the words 'New Page' with the name of the page.
6. Add more content or make further changes as required.
7. Click the 'Save' button.

Screenshot: Choose a template

**Step 1: Choose a page template**

Please choose a template from below:

<table>
<thead>
<tr>
<th>Name</th>
<th>Scope</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>template</td>
<td>Global</td>
<td>Test template</td>
</tr>
<tr>
<td>Documentation</td>
<td>Space</td>
<td>Documentation template</td>
</tr>
<tr>
<td>Staff Birthdays</td>
<td>Space</td>
<td>Staff Birthdays template</td>
</tr>
<tr>
<td>Test</td>
<td>Space</td>
<td>This is just a test</td>
</tr>
</tbody>
</table>

Screenshot: Fill out the form

**Step 2: Fill in template variables**

Choose values for the variables in this template. These values will be automatically inserted into the template for you in the correct locations.

**Archiving Mail Overview**

Confluence allows you to collect and archive mail within each space individually. This is a useful facility that allows you to archive all emails pertaining to a particular project on Confluence alongside it in the same space.

You can download mail from one or more pop-accounts. You can also import mail from mbox files either on your local system or on the Confluence server.

Mail is contained in the 'Mail' tab under the 'Browse Space' view of a space. You may need Space Administrator rights to access this view.

Go to the 'Browse Space' view. There are two ways to browse a space:

- Go to a page in the space and select the option you want from the 'Browse' menu. The corresponding tab of the 'Browse Space' view will open.
- Or click the icon next to the space name on the Dashboard. The 'Pages' tab of the 'Browse Space' view will open.

(If you are not a space administrator for the target space, contact your Confluence administrator to request Space Admin permission.)

From here, you can navigate mail easily and also use the 'Quick Search' to search mail and the attachments it contains.

What would you like to do?

Add a Mail Account
Manage Mail accounts
Import Mail
View Mail
Fetch Mail

Link to Mail

The ability to archive mail applies only to global spaces, not personal spaces. Please see Working with Spaces Overview for information about the differences between global spaces and personal spaces.

**RELATED TOPICS**

Take me back to Confluence User Guide
Adding a Mail Account

When you add a mail account, you are configuring Confluence to download mail from that account and archive it within the space. Since Confluence removes emails from an email account as it is added to the Mail Archive, Confluence must be setup to poll a clone email account rather than the actual account. For example, to archive the actual account sales@company.com to your Confluence Sales space, you must first create a clone account such as conf-sales@company.com that contains the same email content.

Stage 1 - Creating A Clone Email Account

1. Add a new email account on the mail server with the clone email address.
2. Copy all existing emails from the actual account to the clone account.
3. Set up the actual account to bcc sent emails to the clone account.
4. Set up the actual account to forward received emails to the clone account.

Stage 2 - Archive Clone Account To Mail Archive

1. If you are not a space administrator for the target space, contact your Confluence administrator to request Space Admin permission. You need to be a space administrator before you can add a mail account to the space.
2. Go to the ‘Browse Space’ view.
   * Go to a page in the space and select the option you want from the ‘Browse’ menu. The corresponding tab of the ‘Browse Space’ view will open.
   * Or click the icon next to the space name on the Dashboard. The ‘Pages’ tab of the ‘Browse Space’ view will open.
   Now click on ‘Mail Accounts’ under the heading ‘Mail’ in the left panel. This will bring up a new screen listing the existing mail accounts and displaying a link to add a new pop-account.
3. Click ‘Add mail account’ located at the top of the page. This will bring up a form into which you need to enter your account configuration details.
4. Enter the details, (Protocol may be POP/S or IMAP/S) (See below) and click ‘Create’. Configured accounts will have their mail downloaded and removed from the server, so make sure you are downloading from a clone account.

Screenshot Of Adding A POP Account

**Account Name:** Sample User

**Description:** Sample Users Account

**Protocol:** POP

**Hostname:**

**Port:**

**Username:**

**Password:** ************

Create | Test Connection | Cancel

* Account Name: Enter a name for this account by which it will be known in Confluence.
* Description: Provide a description for this account (Optional).
* Protocol: Choose from POP, IMAP, POP3 or IMAPS
* Hostname: Enter the account mail server host name.
* Port: The mail server’s port number will be displayed by default. Do not edit this field.
* Username: Enter a username for this account.
* Password: The account's password.

Note: The ability to import mail applies only to global spaces, so the 'Import' section in the above screenshot does not appear in the 'Space Admin' tab for personal spaces. Please see Working with Spaces Overview for information about the differences between global spaces and personal spaces.

RELATED TOPICS

Importing Mail
Deleting Mail

To delete mail for a space, you require 'Remove Mail' permission which is assigned by a space administrator from the Space Administration screens. See Space Permissions or contact a space administrator for more information.

Only a space administrator can delete all email messages for the space simultaneously.

To delete mail for a space,

1. Go to the 'Browse Space' view.
   - Go to the 'Browse Space' view. There are two ways to browse a space:
     - Go to a page in the space and select the option you want from the 'Browse' menu. The corresponding tab of the 'Browse Space' view will open.
     - Or click the icon next to the space name on the Dashboard. The 'Pages' tab of the 'Browse Space' view will open.

2. Go to the 'Mail' tab. A list of messages in the space is displayed in reverse chronological order.

3. Delete an individual email by clicking the trash icon beside it.
   - If you are a space administrator, you can delete all email messages within a space simultaneously by clicking on the 'Delete All' link at the top of the mail view. Deleted mail is stored under 'Trash' and can be restored by a space administrator from the 'Space Admin' tab.

WARNING

Email messages deleted using the 'Delete All' option cannot be restored.

Fetching Mail

Confluence fetches mail from the server once every 30 minutes.

You need to be a space administrator to manually retrieve new mail from mail accounts.

To manually retrieve mail,
1. Go to the 'Space Administration' view.
   Go to the 'Space Admin' tab of the Browse Space view. To do this:
   - Go to a page in the space, open the 'Browse' menu and select 'Space Admin'. The 'Space Administration' view will open.
     - 'Space Admin' is only displayed if you are a space administrator.

2. Go to the 'Mail' tab.

3. Go to the 'Mail' tab. A list of messages for the space is displayed in reverse chronological order.

4. Click on the 'Fetch new mail' link located above the list of messages. Any new messages will be displayed in order of most recent first.

**Note**
Once mail is fetched, it will be removed from the server.

**Importing Mail**

Confluence allows you to import mail from mbox files located either on your local system or on the Confluence server and archive it within the space.

You need to be a space administrator to import mail for a space.

**To import mail from an mbox file,**

1. Go to the 'Space Admin' in the 'Browse Space' view.
   Go to the 'Browse Space' view. There are two ways to browse a space:
   - Go to a page in the space and select the option you want from the 'Browse' menu. The corresponding tab of the 'Browse Space' view will open.
   - Or click the icon next to the space name on the Dashboard. The 'Pages' tab of the 'Browse Space' view will open.

2. Click on 'Mail Import' under the heading 'Mail' in the left panel. This will bring up a new screen.
   - To import from a Local system, click 'Browse' to select the mbox file. Then click 'Import'.
   - To import from the Server, enter the location of the mbox file on the server in the 'Server' text field and click 'Import'.

**Screenshot: Importing mail**

Import mail from a standard mbox file by either uploading a local file or specifying its location on the server.

- **Local**
  Browse for mbox file on local filesystem:
  
  **Filename:** [Browse... Import]

- **Server**
  Specify location of mbox file on server:
  
  [Import]
The ability to import mail applies only to global spaces, so the 'Import' section in the above screenshot does not appear in the 'Space Admin' tab for personal spaces. Please see Working with Spaces Overview for information about the differences between global spaces and personal spaces.

**Linking to Mail**

Currently in Confluence, while it is possible to link to a mail message, the method is a little cumbersome.

You need to edit in 'Wiki Markup' mode to create a link to an email.

To link to an email,

1. Go to the 'Browse Space' view.

Go to the 'Browse Space' view. There are two ways to browse a space:

   - Go to a page in the space and select the option you want from the 'Browse' menu. The corresponding tab of the 'Browse Space' view will open.
   - Or click the icon next to the space name on the Dashboard. The 'Pages' tab of the 'Browse Space' view will open.

2. Go to the 'Mail' tab. The mail is displayed in reverse chronological order with a default of 30 email messages per page.

3. Move between pages to locate the message you want to link to.
4. Click on the mail message. You will notice in the address bar of your browser that the URL displayed ends in a series of numerals.
5. Copy only the numerals.
6. Click on the 'edit' tab of the page from which you want to link to the message.
7. Paste the numerals between square brackets (as you would when you create any link in Confluence), and then include the dollar sign '$' in front of the numerals.

Here's an example:

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>[$123456]</td>
<td>Re: [CONF-user] ANN: Redirection Macros</td>
</tr>
</tbody>
</table>

Clicking on the link will open up the mail message.

Viewing Mail

In Confluence, each global space can be set up to archive mail.

To view mail messages archived within a particular space,

1. Go to the 'Mail' tab in the 'Browse Space' view.

2. The mail is displayed in reverse chronological order with a default of 30 mails per page. You can move between pages by clicking the << Previous and Next >> links or by selecting a particular page number.

3. Click on a mail message to view its contents.

Navigating Mail

'Find More': These links links at the top of an email message let you search for other emails from the same author or on the same subject. 'Attachments': This link located below the email body allows you to view mail attachments. The link is only displayed if any attachments exist. 'Entire Thread': This link allows you to view the mail's thread, if one exists.

The 'Mail Operations' panel is located to the right of the mail view and displays links to:

- Entire Thread: View the thread that this mail belongs to. This option is only available when the mail belongs to a thread.
- Next By Date: Navigate to the next message.
- Previous By Date: Navigate to the previous message.
- Remove Mail: Remove the current mail from the space.
- Mail Archive: Go to the mail archive view for this space.

Handy Hint

Use the Quick Search facility to quickly locate a mail.

Exporting a Space

Confluence allows you to export a part of, or the entire contents of a space to HTML, PDF or XML.

What would you like to do?
Export from Confluence to PDF
Export from Confluence to HTML
Export from Confluence to XML

RELATED TOPICS
Browsing a space

Take me back to Confluence User Guide

Confluence to HTML

Confluence allows you to export a part of, or the entire contents of a space into a zipped archive of HTML files. This is useful if you want convert your space into a static website.

To export pages to HTML, you will need ‘Export Space’ permission which is assigned by a space administrator. See Space Permissions or contact a space administrator for more information.

To export pages to HTML,

1. Go to the ‘Advanced’ view for the space. To do this:
   - Go to a page in the space, open the ‘Browse’ menu and select ‘Advanced’. The ‘Advanced’ view will open.
2. Click ‘HTML Export’ in the left-hand panel. This option will only be visible if you have ‘Export Space’ permission.
3. Select the check box ‘Include Comments’ if you want to include comments for the pages you are exporting.
4. Select the pages you want to export by selecting the check boxes in the tree view of pages displayed. By default, all pages are selected. You have the option to ‘Check All’ or ‘Clear All’ pages.
   - If you select the check box of a page that contains one or more child or descendent pages, all of these child and descendent pages will also be selected. Similarly, if you clear the check box of such a page, all of its child and descendent pages will also be cleared. This provides a convenient method of exporting subtrees, for example, chapters or sections within a document.
5. Click ‘Export’. This will create a zipped archive of HTML files.
6. Download the zipped archive and extract the files into a folder.

Notes

- Page attachments are placed in individual folders with names in the following format:
  ...\download\attachments\xxxxxx
  where ‘xxxxxx’ is the page ID of the page containing the attachments.
- By default, the ‘Space Details’ page is exported as index.html and displays the space’s details as well as a list of all available pages within it.
- News items are not included within the HTML export. Please cast your vote towards this feature request.

Screenshot: Selecting pages to export
Confluence 3.0 and later versions contain a new PDF Export feature that provides output customisation via Cascading Style Sheet (CSS) modifications. It also provides the ability to add a Table of Contents listing and customised headers, footers and a title page to exported documents too. These customisations are specific to each space in a Confluence installation and require the 'Space Administrator' permission to implement. For more information about implementing PDF Export customisations, see Editing the PDF Stylesheet.

Exporting Single Pages

You can export a single page in Confluence to PDF:

- Go to a page in the space, open the 'Tools' menu and select 'Export to PDF'. The process will begin, and you will be prompted by a series of dialog boxes.

Exporting Multiple Pages or the Entire Space

To export to PDF, you will need 'Export Space' permission which is assigned by a space administrator from the Space Administration screens. See Space Permissions or contact a space administrator for more information.
1. Go to the ‘Advanced’ view for the space. To do this:
   - Go to a page in the space, open the ‘Browse’ menu and select ‘Advanced’. The ‘Advanced’ view will open.
2. Click ‘PDF Export’ in the left-hand panel.
   This option will only be visible if you have the ‘Export Space’ permission.
3. Select the pages you want to export by selecting the check boxes in the tree view of pages displayed. By default, all pages are selected. You have the option to ‘Check All’ or ‘Clear All’ pages. See screenshot below.
   - If you select the check box of a page that contains one or more child or descendent pages, all of these child and descendent pages will also be selected. Similarly, if you clear the check box of such a page, all of its child and descendent pages will also be cleared. This provides a convenient method for exporting subtrees (for example, chapters or sections) of the entire documentation within a space.
4. Click ‘Export’.
5. Download and save the PDF file as prompted. Click or double-click the PDF file name to open it.

**Notes**

Only image attachments which have been inserted into a page are included when exporting to PDF.

To export a PDF containing international text, you need to install a Unicode font in Confluence.

News items are not included within the PDF export. Please cast your vote towards this feature request.

**Screenshot: Selecting pages to export**

Export content from this space as PDF.

You can customise the layout of the PDF export at Space Administration/PDF Stylesheet.

If you have ‘Space Administrator’ permissions, the link to customise the PDF Stylesheet is provided at the top of the page tree, as shown in the image above.

Confluence’s PDF Export feature is designed to handle a wide variety of content. However, in the unlikely situation that the PDF Export process fails, perhaps due to a mishandled customisation, the PDF Export screen will indicate the title of the page in which the problem occurred to help you diagnose the cause of the failure.

**RELATED TOPICS**

Create PDF in another language
Confluence to HTML
Confluence to XML
Editing the PDF Stylesheet

Take me back to the Confluence User Guide.

Create PDF in another language

To export a Confluence page written in another language, you will first need to install the necessary font for that language. This will basically involve uploading a font file to Confluence.

Here are the exact steps on how to do this:

1. Find the appropriate font file

Windows users

All font files in Windows are stored in a directory called

\C:\WINDOWS\Fonts

Unix users

All font files in Unix are stored in the

/usr/share/fonts

Microsoft True Type core fonts such as Verdana can be downloaded from this page: http://corefonts.sourceforge.net/

2. Copy the font file

Simply copy the file into a temporary folder (for example a folder on the Desktop).

3. Upload the file

- Navigate to the Administration > PDF Language Support screen and upload the file you copied in step one.
- Click 'Install'. That's it.

Please note the only font files supported are true type fonts and true type collections (file extensions are *.ttf and *.ttc).

We recommend you to use Unicode font Verdana for correct character encoding and exporting to pdf.

Confluence to XML

Confluence allows you to export a part of, or the entire contents of, a space into a zipped archive of XML files.

This is useful if you want to make a backup of the space, export the space to another Confluence instance, or use the data from the space in another application. Please note that there are a few restrictions when Restoring a Space, and that huge spaces exported for backup-purposes may benefit from other means of backup - see Alternative Backup Strategy.

To export to XML, you will need 'Export Space' permission which is assigned by a space administrator. See Space Permissions or contact a space administrator for more information.

Site administrators can import a space from a zipped XML archive.

To export to XML,
1. Go to the ‘Advanced’ view for the space. To do this:

   - Go to a page in the space, open the ‘Browse’ menu and select ‘Advanced’. The ‘Advanced’ view will open.

2. Click ‘XML Export’ in the left-hand panel.
   This option will only be visible if you have ‘Export Space’ permission.

3. Select the check box ‘Include Comments’ if you want to include comments made on the pages you are exporting.

4. Select the check box ‘Backup Attachments’ if you want include the images and other files attached to the pages.

5. Select either ‘All’ or ‘Visible to you’. These options are explained below:
   - **All** — Export all content in the space, including pages that are protected by page-level restrictions which will prevent you from viewing the pages themselves. This option is available only to space administrators and Confluence administrators. It allows you to make a complete and comprehensive export of a space for backup purposes.
   - **Visible to you** — Export only content you can see. This is the default option.

6. If you choose ‘Visible to you’, you will then be able to select the pages you want to export. Select the relevant check boxes in the tree view of pages displayed. By default, all the pages are selected. You have the option to ‘Check All’ or ‘Clear All’ pages.

   If you select the check box of a page that contains one or more child or descendent pages, all of these child and descendent pages will also be selected. Similarly, if you clear the check box of such a page, all of its child and descendent pages will also be cleared. This provides a convenient method of exporting subtrees, for example, chapters or sections within a document.

7. Click ‘Export’. This will create a zipped archive of XML files.

Screenshot: Exporting a space

If you are running Confluence behind Apache HTTP Server and are facing timeout errors, please consider creating the export directly from Tomcat, instead of going through Apache. This will speed up the process and prevent timeouts.

- Confluence to XML

Take me back to the Confluence User Guide.
Editing the PDF Stylesheet

Confluence's PDF Export feature addresses the most highly voted improvement request for Confluence — more control over PDF exporting. Users can customise their PDF exports using a PDF Stylesheet, which is specific to each space in a Confluence installation. The following aspects of PDF exports can be customised:

- Page and margin sizes
- Headers and footers, each with customisable content such as page numbering
- A customisable title page, which can incorporate images
- Built-in support for table of contents with page numbering

Most PDF Stylesheet customisations are handled using Cascading Style Sheets (CSS), while customisations to headers, footers and the title page are handled using a combination of custom HTML and CSS. Hence, you should be familiar with these technologies (or may require some familiarisation with them first), before implementing the customisations you require.

On this page:

- Customising the style of PDF exports
- Basic Customisations
  - Page Customisations
    - Customising the Page Size
    - Customising the Page Margins
  - Customising the Table of Contents
    - Disabling the Table of Contents
    - Change the Leader Character
  - Adding a Title Page to PDF-Exported Space or Subsection
  - Adding Headers and Footers
    - Adding page numbering to a header or footer
  - General Formatting

Customising the style of PDF exports

To customise the PDF Stylesheet, you will need the ‘Space Administrator’ permission which is assigned by a space administrator from the Space Administration screens. See Space Permissions or contact a space administrator for more information.

To customise the PDF Stylesheet:

1. Go to the ‘Space Admin’ tab of the Browse Space view. To do this:
   - Go to a page in the space, open the ‘Browse’ menu and select ‘Space Admin’. The ‘Space Administration’ view will open.
   - ‘Space Admin’ is only displayed if you are a space administrator.
2. Click ‘PDF Stylesheet’ in the left-hand panel. The main screen displays the current contents of your PDF Stylesheet customisations. The PDF Stylesheet is divided into the following four sections and allow for modifications to the:
   - PDF Export Stylesheet - containing all CSS rule customisations applied to the pages in the space.
   - PDF Export Title Page - containing custom HTML that generates the document's title page.
   - PDF Export Header - containing custom HTML that generates headers throughout the document.
   - PDF Export Footer - containing custom HTML that generates footers throughout the document.
3. Click the 'Edit' button and each of these four sections expands to an editable text box.
4. Enter your customisations into each section as required.

Refer to the Basic Customisations section for examples of typical customisations that can be added to your PDF Stylesheet. Once you are familiar with the implementation of basic PDF stylesheet customisations, you may wish to try out some Advanced Customisations.

- If no PDF customisations are defined on the PDF Stylesheet screen, the PDF Stylesheet feature's default CSS rules will be applied to your PDF exports. Furthermore, no title page, header or footer will be shown in these exports either.
  - The PDF Stylesheet's default CSS rules are available for download. Any rule defined in (but not limited to) this file can be customised and added to the PDF Export Stylesheet section.
- In general, you can override any default CSS rule by redefining it with your own customisations in the PDF Export Stylesheet section.
• As shown in the Confluence to PDF topic, there are two PDF export methods:
  • Single pages via the 'Tools' menu -> 'Export to PDF' function on a page or blog post ('single page exports')
  • One or more pages in a space via the 'Advanced' view ('space exports')

• All customisations, which include those made to your 'PDF Export Stylesheet', 'Title Page', 'Header' and 'Footer', apply to space exports. However, only the 'PDF Export Stylesheet' customisations inherently apply to single page exports.

• To make your 'PDF Export Header' and 'Footer' customisations apply to a single page exported to PDF, either:
  • use the 'space export' method to export that single page only, or
  • if your header and footer customisations contain only text, follow the appropriate customisations provided in the Advanced PDF Stylesheet Customisations topic.

Basic Customisations

Page Customisations

Modifications to page and margin sizes are made in the @page CSS rule.

To make changes to this rule, you would implement the following type of code in the 'PDF Export Stylesheet' section of the space's PDF Stylesheet.

```css
@page
{
  /*Page specific styles (that is, customisations of properties) go here*/
}
```

Customising the Page Size

The default page size is based on the locale of your Confluence server. Hence, if this server was located in the US, the default paper size of your PDF export would be US Letter size (8.5 inches wide by 11 inches long). If the server was located in Australia, the default paper size would be A4 (210 mm wide by 297 mm high).

To modify the page size to A4, add a size property to the top of the rule like this:

```css
@page
{
  /*The A4 paper size is 210 mm wide by 297 mm high*/
  size: 210mm 297mm;
}
```

More information about paper sizes can be found on Wikipedia.

Customising the Page Margins

To add a margin of 15 mm to a paper size of A4, your CSS @page rule would look like this:

```css
@page
{
  size: 210mm 297mm;
  margin: 15mm;
}
```

Customising the Table of Contents

By default, a table of contents will be generated after the title page, or at the beginning of the document if the 'PDF Export Title Page' is not defined. The look and layout of the table of contents is completely customisable by defining the appropriate CSS rules in the 'PDF Export Stylesheet'.

For details about the CSS rules governing the default styles applied to the table of contents output in PDF exports, download the default CSS rules (from the link above) and examine the specific rules with toc in its name.

Disabling the Table of Contents

To prevent the table of contents being generated in your exported PDF document, add the div.toc rule to the 'PDF Export Stylesheet'
section of the space's PDF Stylesheet and set its `display` property to `none`:

```
div.toc {
  display: none;
}
```

**Change the Leader Character**

The leader character is used to visually link the name of a heading in the table of contents list with its page number, which is usually aligned to the page's right-hand margin. By default, the leader character is the '.' (dot) character. However, it can be changed by customising the leader character CSS rule `span.toclead:before` and adding this to the 'PDF Export Stylesheet' section of the space's PDF Stylesheet.

To change this to a solid line, modify this CSS rule accordingly:

```
span.toclead:before {
  content: leader(solid);
}
```

To change this to spaces (that is, blank space), modify this CSS rule to:

```
span.toclead:before {
  content: leader(space);
}
```

Be aware that using a space as a leader character can make the table of contents list difficult to read.

**Adding a Title Page to PDF-Exported Space or Subsection**

You can create a title or cover page for an PDF-exported space or subsection using XHTML. Use the 'PDF Export Title Page' section of the space's PDF Stylesheet to do this. The following XHTML code example uses an inline CSS rule to generate a title page.

```
<div class="fsTitlePage" style="margin-left:auto;margin-top:75mm;margin-right:auto;">
  <img src="/download/attachments/12345/titlepage.png"/>
</div>
```

In the example above, an image called 'titlepage.png' will be centred in the middle of the page. This image is attached to a Confluence page and is referenced via its relative URL (that is, without the Confluence site's base URL component). You can obtain the URL of an image attached to a Confluence page by viewing the list of attachments on that page and moving your mouse over the attachment's name. The URL of the image should appear in your browser's status bar or you can copy the link.

**Adding Headers and Footers**

Headers and footers can be added to a PDF-exported space or subsection also using XHTML. Use the 'PDF Export Header' and 'PDF Export Footer' sections of the space's PDF Stylesheet to create a custom header and footer, respectively. For simple headers and footers, plain text is sufficient. The following example added to a header or footer will create a simple copyright notice.

```
Copyright © 2009, Atlassian Pty Ltd.
```

**Adding page numbering to a header or footer**

To add page numbering to your documentation, you need to combine some customised XHTML in the header or footer along with some customised CSS in the 'PDF Export Stylesheet'.

First, create a header or footer with an empty span element and give it a unique id, for example `pageNumber` (although this could be anything). This is the page number 'place holder' in your exported PDF document.

```
<span id="pageNumber"/>
```

Next, create the following CSS selector rule for this empty span and add it to the 'PDF Export Stylesheet':
Analysing this CSS selector rule in more detail, the `#pageNum` selects the XHTML element with the specified id of "pageNum", which is the span element we created for the header or footer. The `:before` part of the selector is a 'pseudo class' that allows the insertion of content before the span element is processed. The `counter(page)` is a function that returns the current page number as its content. Finally, the `content` property inside the rule tells the CSS processor that dynamic content (that is, an incrementing page number) is to be inserted before the span tag.

**General Formatting**

You can also use the stylesheet to customise the output of just about anything else that will influence the look and feel of the final document. This includes fonts, tables, line spacing, macros, etc. The export engine works directly from the HTML output produced by Confluence. Therefore, the first step in customising something would be to find a selector for the HTML element produced by Confluence or the Confluence macro. Next you would add a CSS rule to the 'PDF Export Stylesheet' and your customisation would appear in the PDF export.

**RELATED TOPICS**

Advanced PDF Stylesheet Customisations

This topic provides information and details on popular PDF stylesheet customisations. These expand upon the basic customisations described in the Editing the PDF Stylesheet topic.

On this page:

- Page Customisations
  - Changing the Page Orientation
  - Customising Specific Page Margins
- Page Header and Footer Customisations
  - Adding Headers and Footers to Single Page Exports
  - Adding Images to Headers and Footers
- Page Selector Rules

**Page Customisations**

Modifications to page and margin properties are made in the `@page` Cascading Style Sheet (CSS) rule. As described in Editing the PDF Stylesheet, all CSS rule customisations are implemented in the 'PDF Export Stylesheet' section of the space's PDF Stylesheet.

**Changing the Page Orientation**

To change the page orientation of your PDF space exports, reverse the order of the values declared in the `@page` rule's `size` property, since the first and second values of this property represent the width and height of the page, respectively.

For example, to generate PDF space exports in A4-sized landscape orientation, your `@page` rule might look like this:

```css
@page
{
/*A4-sized pages in landscape orientation are 297 mm wide by 210 mm high*/
size: 297mm 210mm;
}
```

**Customising Specific Page Margins**

To set the margins of each side of a page independently of the other, you can declare each margin size in the `@page` rule using the following properties:

<table>
<thead>
<tr>
<th>Properties</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>margin-top</td>
<td>Margin height at the top of the page.</td>
</tr>
<tr>
<td>margin-bottom</td>
<td>Margin height at the bottom of the page.</td>
</tr>
<tr>
<td>margin-left</td>
<td>Margin width on the left of the page.</td>
</tr>
</tbody>
</table>
Margin width on the right of the page.

For example, to generate PDF space exports with top and bottom margins of 1 inch and left and right margins of half an inch, your \page rule might look like this:

```css
@page
{
  margin-top: 2.54cm;
  margin-bottom: 2.54cm;
  margin-left: 1.27cm;
  margin-right: 1.27cm;
}
```

**Page Header and Footer Customisations**

**Adding Headers and Footers to Single Page Exports**

As mentioned in Editing the PDF Stylesheet, custom headers and footers by default, only apply to 'space exports' and not 'single page exports'. However, it is possible to add CSS rules to your PDF export stylesheet that allow custom headers and footers to appear in single page exports.

To make custom headers appear in single page exports, you need to define custom \top-left, \top-center and \top-right rules within your \page rule for content that appears within the left-hand side, centre and right-hand side of your page's header area.

Similarly, to make custom footers appear in single page exports, you need to define custom \bottom-left, \bottom-center and \bottom-right rules within your \page rule for content that appears within the left-hand side, centre and right-hand side of your page's footer area.

To add a document title to the centre of a header and a page number to the centre of a footer (with the word 'Page' preceding the page number), you can add the following header (\top-center) and footer (\bottom-center) rules within the \page rule of your PDF export stylesheet like this:

```css
@page
{
  /* Any page-specific properties */
  @top-center
  {
    content: "Document Title Goes Here";
    font-family: ConfluenceInstalledFont, Helvetica, Arial, sans-serif;
    font-size: 8pt;
  }
  @bottom-center
  {
    content: "Page " counter(page);
    font-family: ConfluenceInstalledFont, Helvetica, Arial, sans-serif;
    font-size: 8pt;
  }
  /* Any other page-specific rules */
}
```

- The font-family and font-size properties in these header and footer rules ensures that the header and footer text is rendered in the same default font style used for the body text (based on the default CSS rules).
- Please note that it is not possible to use this method to insert images (stored as attachments within your Confluence instance) into the headers and footers of single page exports.

**Adding Images to Headers and Footers**

To insert an image into a header or footer, you will need to edit the 'PDF Export Header' and 'Footer' sections of the PDF stylesheet and use an XHTML `img` element with `src` attribute to refer to an image attachment within your Confluence instance. This is usually placed within a `div` element container.

To add an image to the left of the header, you can add XHTML code to the 'PDF Export Header' that references the image, like this:

```html
<div style="margin-top:10mm">
  <img src="/download/attachments/12346/header-image.png"/>
</div>
```

In the example above, an image called 'header-image.png' is attached to a Confluence page and is referenced via its relative URL (that is, without the Confluence site's base URL component). You can obtain the URL of an image attached to a Confluence page by viewing the list
of attachments on that page and moving your mouse over the attachment's name. The URL of the image should appear in your browser's status bar or you can copy the link.

This code uses an inline CSS property in the `style` attribute to set formatting properties specific to this header image. The `margin-top:10mm` property forces the image away from the top of the page by 10mm. This comes in handy when your header image is large enough to touch or spill over the top of the page. Likewise, for footers, you can use the `margin-bottom:XXmm` property to force an image away from the bottom of the page by 'XX' mm.

Be aware that very large images can spill over into the body of a page or alter the position of text or other elements used within a header or footer. In such situations, it is recommended that you reduce the size of the image and then re-upload it to your Confluence instance.

By default, a header or footer image is aligned to the left-hand side of the page. However, you can align this image to the centre or right-hand side of a page by adding either the `text-align:center` or `text-align:right` properties, respectively to your `style` attribute. For example, to align the header image (above) to the right-hand side of the page, your `style` attribute would look similar to this: `style="margin-top:10mm; text-align:right"`.

To add an image to a footer, add similar XHTML code consisting of an `img` element and `src` attribute to refer to an image attachment within your Confluence site. Incorporate the inline CSS property `margin-bottom` to separate the image aware from the bottom of the page if necessary.

**Page Selector Rules**

If your PDF exports are destined for double-sided printed media (for example, books), you can define different customisations for left- or right-hand pages. This is achieved through two CSS pseudo-classes 'page selectors' that you define as separate rules within the PDF export stylesheet. Use the `:left` pseudo-class with the `@page` CSS rule to define customisations specific to left-hand pages and the `:right` pseudo-class with `@page` to define customisations for right-hand pages.

You can use these page selector CSS rules in your PDF export stylesheet to define alternating left and right margins that allows room for binding a double-sided document, as shown in the following example:

```css
@page {left {
  margin-left: 3cm;
  margin-right: 1.27cm;
  /* Any other left-hand page-specific properties and rules */
}

@page {right {
  margin-left: 1.27cm;
  margin-right: 3cm;
  /* Any other right-hand page-specific properties and rules */
}
```

**Exporting to a Word document**

Confluence allows you to export a single page into a Word document. This is extremely useful for emailing around content to non-Confluence users, printing a document or just creating a backup in Word.

You will require 'Export Pages' permission to export a page to a Word document.

To export to a Word document,

1. Go to the 'Export to Word' option for the page. To do this:
   - Go to a page in the space, open the 'Tools' menu and select 'Export to Word'. The process will begin, and you will be prompted by a series of dialog boxes.
2. By default, this will create a Word document with the same name as the Confluence page.

**Importing Content Into Confluence**

Confluence stores all page content in Confluence's wiki markup syntax.

On this page:

- Importing Content from Other Confluence Sites
- Importing Content from Other Wikis
- Importing Content from an Office Document
- Importing Web Content
- Importing Other Non-Wiki Content

**Importing Content from Other Confluence Sites**
For content originating from other instances of Confluence:

- If the Confluence major versions are the same, export the space from the originating Confluence site and import it into the destination Confluence site.
- If the Confluence major versions are different, you can use an intermediate server to migrate versions.

Page history, attachments, and wiki markup will be preserved and you will be able to do multiple pages at once. The drawbacks are that it may be inconvenient if the Confluence versions differ, and you cannot have a duplicate space key on the destination instance. (You cannot import a space that already exists, and this is defined by the space key.)

**Importing Content from Other Wikis**

Check whether the Universal Wiki Converter can import the content. See Importing Content from another Wiki.

**Importing Content from an Office Document**

The Office Connector in Confluence allows you to import an Office document into Confluence, so that the document's content is copied onto one or more Confluence pages. See Importing an Office Document into Confluence.

**Importing Web Content**

Here are some options for importing or displaying web content on a Confluence page:

- Use the Widget Macro to display videos, slide shows, twitter chats, documents and more, sourced from other web sites and displayed on your Confluence page.
- Convert a HTML file to a Confluence page using the HTML To Confluence Converter plugin.
- Embed an external web page into Confluence with the Html Include macro.
- Use HTML code in a page with the HTML macro.

**Importing Other Non-Wiki Content**

Importing non-wiki markup into Confluence requires a conversion process:

- Text with basic formatting can be pasted directly into the Rich Text Editor. This includes simple Word documents or web pages.
- Files such as Microsoft Excel documents can be imported using a content converter plugin.
- Confluence pages saved to disk can be imported from disk.

**RELATED TOPICS**

Working with the Office Connector
Importing Content from another Wiki

Take me back to Confluence User Guide

**Importing Pages from Disk**

Confluence allows you to import text files from a disk or a directory on the Confluence server, and convert them into corresponding Confluence pages. Each file will be imported as a Confluence page with the same name as the file.

You need to be a System Administrator to import text files.

To import text files,
1. Go to the ‘Space Admin’ tab of the Browse Space view. To do this:
   - Go to a page in the space, open the ‘Browse’ menu and select ‘Space Admin’. The ‘Space Administration’ view will open.
   - ‘Space Admin’ is only displayed if you are a space administrator.

2. Click on the ‘Import pages from disk’ link in the left panel under the heading ‘Import’. This will display a new screen.

3. Type in the directory’s path in the ‘Import directory’ text field.

4. Check ‘Trim file extensions’ to remove file extensions when converting the files to Confluence pages. Note that the Confluence pages will take their titles from the files’ names (including their extensions). So to avoid having page titles with the suffix ‘txt’ in them, make sure you check this box.

5. Check ‘Overwrite existing pages’ if you want to replace existing Confluence pages with the same page title.

6. Click ‘Import’.

**Screenshot: Importing text files**

<table>
<thead>
<tr>
<th>Import directory:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Trim file extensions</td>
</tr>
<tr>
<td>Overwrite existing pages</td>
</tr>
</tbody>
</table>

The ability to import pages from disk applies only to global spaces, so the ‘Import’ section in the above screenshot does not appear in the ‘Space Admin’ tab for personal spaces. Please see Working with Spaces Overview for information about the differences between global spaces and personal spaces.

**RELATED TOPICS**

Take me back to Confluence User Guide

**Space Backup and Restore**

Confluence can backup all the content, comments and attachments for a space. The process involves converting the data in the space into XML format. The end product is a zip file that contains XML file(s) and optionally, all the attachments in the space. To transfer this data to another Confluence site, you simply restore this zip file.

*Creating a Space Backup*

Instructions on how to create a backup for a space can be found here.

*Restoring/Importing a Space Backup*

Instructions on how to restore or import the backup of a space can be found here.

**Site Backup and Restore**

Atlassian suggests establishing a backup strategy using a native database tool for a production instance of Confluence.

By default, Confluence backs up all data and attachments once a day to a backup file. These files are called XML site backups, stored in the backups directory of Confluence home. You can also create XML site backups manually. This mechanism was created with small to medium-sized deployments of Confluence in mind. It is not made for large deployments with lots of pages and attachments (see below)

- Restore your site from an XML site backup
XML site backups are fine for most small to medium sized instances of Confluence, containing a few thousand pages and attachments. However, large instances of Confluence will find backups may become slow to create and use large amounts of disk space.

**Backups For Large Instances**

XML site backups are unsuitable for instances of Confluence that contain thousands of pages, as XML backups take progressively longer to complete as the amount of text increases. Another issue with XML site backups is that Confluence instances with gigabytes of attachments will consume disk space rapidly. This is because each site backup contains all content needed for a site restore. For example, if a 1 gig instance of Confluence is backed up daily, it will create 30 gig of backups per month if left unattended. When administering a large instance, you can reduce disk space by setting XML site backups to exclude attachments, then manually scheduling a backup of your attachments from the Confluence home directory or database. The backup manager can save space by saving changed files instead of all content.

<td>Unacceptable</td>
<td>Manual backup of database and attachments</td>
</tr>
</tbody>
</table>

**Creation Delay** is the time it takes to create an XML site backup minus attachments. **Disk Usage** can be estimated by multiplying the frequency of your XML site backups by their current size.

**Manual Backups**

Confluence's attachment storage configuration can be set to store attachments in the Confluence home directory, or in the database.

**Database Backup**

Use your Database Administration Tool to create a backup of your Confluence database. If your database is storing your attachments, importing this later will restore all content. For instances with big attachments, please note that currently Confluence migrate attachments in a single transaction: CONF-9888.

**Attachment Backup**

If stored on the filesystem, attachments are placed under the attachments directory of your Confluence home directory. Copy this directory to create a backup of all attachments.

To restore from these backups, please refer to Restoring Data from other Backups.

Alternative Backup Strategy
Backup FAQ

**Alternative Backup Strategy**

**Confluence's Built-in Backup**

Confluence automatic daily XML backup is ideal if you:

- are evaluating Confluence
- do not have database administration familiarity, and your Confluence installation is small

But once your Confluence installation reaches more than a few thousand pages, the XML backup facility can be inefficient compared to your database's own backup tools.

**Establishing a Production System Backup Solution**

The built in backup functionality in Confluence requires a lot of memory to run and is less reliable when restoring. Atlassian recommends establishing an alternative database backup strategy:

- Create a backup or dump of your database using tools provided by your database
- Create a file system backup of your Confluence home directory

Once this is in place, disable the daily backups from Administration > Daily Backup Admin.

We want to stress that creating these two backups is just as good as having a Confluence XML backup, and a lot more robust for large production instances. You will be able to restore your whole site, including all data, attachments and configuration information intact with these two backups. We have written up a document on how to do this here.

**Step by step instructions**
Take a look at the Migrating Confluence Between Servers document for instructions on restoring a backup using this technique.

Other processes

XML backups are described and used for other processes in Confluence, like upgrading and moving servers. Using the backup strategy described here will work for those processes. Our upgrade guide does not require the use of an xml backup (an old upgrade procedure, and the JIRA upgrade guide use XML backups for upgrading); and our migrate server procedure - used to set up a test server - can leverage an sql dump as well.

The only process that requires the XML backup is the database migration procedure. Large data sets will require third party database migration tools.

Site Backup and Restore
Backup FAQ

Security Overview

Open or closed? It's your call.

Confluence gives you the choice to make the site as open or as closed as you wish. Here are some points to consider:

- As a tool for communication and collaboration, Confluence is at its best when all your users can participate fully.
- So it's advisable not to restrict users unless you have a good reason for doing so.
- Confluence keeps a history of all changes to pages and other content. So it is easy to see who has changed what, and to reverse any edits if required.

There are three levels of permissions in Confluence.

Levels of Permission

Global Permissions

Global permissions are site-wide permissions, and are assigned by administrators. Confluence allows two levels of administrator permissions:

- System Administrator - Users with this permission can perform all the Confluence administrative functions.
- Confluence Administrator - Users with this permission can perform most of the Confluence administrative functions, but excluding those functions which could compromise the security of the Confluence system.

Users with 'System Administrator' or 'Confluence Administrator' permission can assign permissions to other users. For full details, please refer to the overview of global permissions in the Administrator's Guide.

Space Permissions

The permission to create a new space or to administer one is granted by a Confluence Administrator from the global Administration Console.

Every space has its own independent set of permissions. These permissions determine the access settings for different users of the space. In order to assign these permissions to other users, a user must be a space administrator i.e. must have the 'Admin' permission for that space.

See Users and Groups to learn how these permissions are assigned.

Page Restrictions

You can set page-level restrictions, if you have the 'Restrict Pages' permission within the space concerned.

Page restrictions allow you to control who can view or edit individual pages. To set page restrictions, edit the page and use the page restriction options below the text-entry box.

More Information

How do space permissions and page restrictions work together?

Example: In the HR (Human Resources) space, everyone in the organisation has the 'View' space permission, but only the HR team has the 'Pages --> Create' space permission (i.e. the ability to create and edit pages in the space). A member of the HR team starts to create a new page called 'Annual Leave Policy'. Because the page is not yet finished, she sets the 'Viewing' page restriction so that only the HR team can view the page. When the page is finished, she will remove the 'Viewing' restriction so that everyone in the company can see the page.
How do space permissions and page restrictions affect links?

Space permissions and page restrictions affect how links between pages are displayed to a visitor:

- if the link points to a page in a space to which the visitor does not have 'View' space permission, the link will not be rendered at all.
- if the visitor has 'View' space permission, but page restrictions prohibit her from viewing the page, the link will be rendered but an 'Access Denied' message will be displayed when she clicks the link.
- if the visitor has 'View' space permission, and is not restricted from viewing the page, the link will display and behave as normal.

Links to attachments are also affected:

- if the visitor does not have permission to view the page to which the attachment is attached, the link will not be rendered.

**Warning**

If you misconfigure a space so that nobody has access to administer it any more, you will need to have someone in the 'confluence-administrators' group fix the permissions for you.

RELATED TOPICS

Users and Groups
Viewing Space Permissions
Assigning Space Permissions
Page Restrictions

Take me back to Confluence User Guide

Page Restrictions

Page restrictions allow you to control who can view or edit individual pages. You can set the page restrictions when editing a page, using menus below the text-entry box.

When a page you are viewing has restrictions applied, a small padlock icon appears next to the page byline. Clicking the padlock will take you to the Information View, where full details on the page restrictions are displayed.

In order to set or modify page restrictions, you need to have both:

- 'Restrict Pages' permission in the space to which the page belongs (since page restrictions operate within the bounds of space permissions).
- Permission to edit the page itself. That is, if a user is prevented from editing a page through page restrictions, they are also prevented from changing the restrictions themselves.

Page Security Rules

Users can only view page or space content for which they (or a group they are in) have 'View' permission. Pages that a user does not have 'View' access to are referred to as 'inaccessible' pages. Visit Inaccessible Page to see how Confluence deals with pages a user cannot view:

- Anonymous users are directed to the login page.
- Logged-in users are shown a permissions error page.

It is not possible to conceal the existence of pages, though you can restrict 'View' access to page content. To keep the existence of a page or space secret, do not link to it from other sources.

Users will still be able to find the page if they know its URL. But they will not be able to view the content if they don't have the correct permissions.

Inherited Restrictions and Child Pages

If a page has its 'View' restriction set, that restriction will be inherited by all its children (and their children, and so on). If a 'View' restriction is added to a page that has already inherited page restrictions from its parent, users must satisfy both restrictions in order to see the page.

'Edit' restrictions are not inherited from the parent page, only from the space.

Example of Child Page Restrictions

Consider the page 'Documents', with a child page 'Executive', which itself has a child page 'Payroll'. To begin with, anyone who can view the space to which these pages belong can see all three pages.

For security reasons, 'View' restrictions are set on the 'Executive' page, restricting it to the 'mycompany-management group'. At this point, anyone can still see the 'Documents' page, but you must be in the 'mycompany-management group' in order to view either 'Executive' or 'Payroll'.

Since 'Payroll' information is considered particularly private, the 'Payroll' page then has its page restrictions set to only allow members of the
'mycompany-financial' group to view it. At this point, anyone can see the 'Documents' page, only members of 'mycompany-management' can see 'Executive', and only users who are members of both the 'mycompany-management' and 'mycompany-financial' groups can view 'Payroll'.

**How to Open Part of a Space**

Often there are cases for which a section of a space should be opened to a group or set of users (for this example, we'll call them group B), but the rest of the space should not be visible to your main users (for this example, we'll call them group A). In this case:

1. Add 'view' permission for both groups A and B in space permissions.
2. Move the page to be opened to the root of the space. When browsing the pages in the space, your normal space home page and this page should both be at the root level.
3. Add a page restriction to allow Group A and B to see this page.
4. Add a page restriction to your main landing page for Group A, thereby excluding this set of pages from Group B.

You can repeat this with any page hierarchy.

---

**Administrators**

- Space administrators are responsible for the management of a space and its contents. They therefore have the ability to remove all restrictions from a page (as described in 'Viewing Restricted Pages'). This means that space administrators can view and edit all content in the space.
- Users who are members of the 'confluence-administrators' group ('super-users') can view all pages regardless of the page restrictions. To be able to edit the page, you will need to remove the restriction from it first – go to 'Space Administration' > 'Restricted Pages'.

---

**You cannot exclude yourself**

As creator or editor of a page, you cannot use page restrictions to deny yourself access to the page. Confluence will automatically add your username into the list of users/groups allowed to view/edit the page. If you remove your username, Confluence will put it back again.

---

**What would you like to do?**

- View a Page's Restrictions
- Set a Page's Restrictions
- View All Restricted Pages

**RELATED TOPICS**

- Working with Pages

**Take me back to Confluence User Guide**

**Setting a Page's Restrictions**

Page restrictions control who may view or edit a specific page, within the bounds of the space permissions. This gives the space administrator control over who can access their space, and within that the page editor can control access to the page.

- **Viewing restrictions** make the page invisible to everyone except the chosen users/groups.
- **Editing restrictions** prevent everyone except the chosen users/groups from editing the page.

You can choose as many users/groups as you like.

In order to set or modify page restrictions, you need to have the 'Restrict Pages' permission in the space to which the page belongs, as well as permission to edit the page itself.

**To set 'viewing' restrictions on a page,**
1. Click the 'Edit' link at the top of the page.
2. The word 'Restrictions' will now appear at the bottom of the page (above 'Labels'). Click the 'Edit' link next to the word 'Restrictions'.
3. A form will appear below the word 'Restrictions', as shown in the screenshot below. The option 'Restrict viewing of this page' will be selected by default.
4. Choose the appropriate user(s) and/or group(s) who you want to allow to view the page:
   - To choose just yourself, click 'Choose me'.
   - To choose a particular user, you can either:
     - If you are unsure of the user's exact name, click the 'Choose users' link to display the 'User Search' popup window. Use the search options to find the required user. Select the appropriate user(s), then click the 'Select user(s)' button. (You can read more about searching for users.)
     - Type the user's name (or a list of names, separated by commas) into the 'Enter user/group name(s)' box, then click the 'Add' button.
   - To choose a particular group(s), you can either:
     - If you are unsure of the group's exact name, click the 'Choose groups' link to display the 'Group Search' popup. Type part of the name, then click the 'Search' button to display a list of matching groups, e.g. to search for groups whose names start with 'finance', type 'finance'. Select the appropriate group(s), then click the 'Select group(s)' button.
     - Type the group name (or a list of groups, separated by commas) into the 'Enter user/group name(s)' box, then click the 'Add' button.
5. Click the 'Save' link at the bottom of the page.

Screenshot — Adding restrictions to a page

To set 'editing' restrictions on a page,

1. Click the 'Edit' link at the top of the page.
2. The word 'Restrictions' will now appear at the bottom of the page (above 'Labels'). Click the 'Edit' link next to the word 'Restrictions'.
3. A form will appear below the word 'Restrictions', as shown in the screenshot above. Select 'Restrict editing of this page'.
4. Choose the appropriate user(s) and/or group(s) that you want to allow to edit the page, as described for 'viewing' restrictions above.
5. Click the 'Save' link at the bottom of the page.

Checking restrictions are applied to a page

When a page you are viewing has restrictions applied, a small padlock icon appears next to the page byline. Clicking the padlock will take you to the 'Information View', where full details on the page restrictions are displayed.

Note

View and edit restrictions apply to all users including space administrators. However, space administrators can remove any restriction on a page. See Viewing Restricted Pages.

Site Administrators and their permissions

All site administrative functions are performed from the Administration Console. You need to have System Administrator or Confluence Administrator permissions to access the Administration Console.

The Confluence permission scheme allows two levels of administrator permissions:

- **System Administrator** – full administrative access to Confluence.
- **Confluence Administrator** – access to most of the Confluence administrative functions.

Please refer to the overview of global permissions in the Administrator’s Guide for full details.

RELATED TOPICS

Users and Groups

Take me back to Confluence User Guide

Space Administrators and their permissions

A space administrator is a user with the ‘Space Admin’ permission for a space. This permission itself is assigned from the Space Administration screens by a space administrator.

Who is a space administrator?

The person who creates a space is automatically the administrator of that space. That person can then assign other space administrators as required.
Confluence administrators are not necessarily space administrators

- A user who has the 'Administer Confluence' permission is not automatically a space administrator for a particular space. In order for them to be a space administrator, they must belong to a group which has space administration rights on the space, or their username must be specifically granted space administration rights on the space.
- Users who are members of the 'confluence-administrators' group do automatically have space administration permissions for all spaces.

Refer to the Administrator's Guide for more details about Confluence administrator permissions.

What can a space administrator do?

A space administrator has permission to do anything in the space regardless of any other setting. Space administrators are responsible for the management of a space and its contents. Note that page permissions affect space administrators differently from other users.

Space administrators can:

- view all content in the space. If there are page permissions that restrict the viewing of a page to a single user, or to a group to which the space administrator doesn't belong, a space administrator can still view the page by removing the restriction.
- edit all content on any page in the space.
- remove restrictions from any page in the space (using the Space Administration interface).
- grant themselves any other space permissions (e.g. permission to set restrictions on a particular page).

All space administration functions are performed from the 'Space Admin' tab under the 'Browse Space' view of a space. You need to be a space administrator to access the Space Administration screens.

RELATED TOPICS

Space Permissions Overview
Take me back to Confluence User Guide

Space Permissions Overview

Every space has its own independent set of permissions.

Space permissions can only be granted by a space administrator. A space administrator has permission to do anything in the space regardless of any other setting.

Permissions can be assigned to any group, to any individual user in the Confluence-User group, and to users in the Anonymous group.

These are the different permissions that can be assigned at the space level:

- **View:** user can view this space's content, including the space's details, and its pages and news items (blog posts)
- **Pages:**
  - Create - user may create and edit pages in this space.
  - Export - user may export pages in this space.
  - Restrict - user may apply page level permissions.
  - Remove - user may remove pages in this space.
- **News** (i.e. blog posts):
  - Create - user may post news items in this space.
  - Remove - user may remove news items in this space.
- **Comments:**
  - Create - user may make comments in this space.
  - Remove - user may remove comments from this space.
- **Attachments:**
  - Create - user may add attachments in this space.
  - Remove - user may remove attachments from this space.
- **Mail:**
  - Remove - user may delete individual mail items.
- **Space:**
  - Export - user may export content from this space.
  - Admin - user has administrative permissions over this space.
Warning
If you deny all administrative access to a space by mistake, so that nobody has access to administer the space any more, you will need to ask someone in the confluence-administrators group to fix the permissions for you.

Assigning Space Permissions

Space permissions can be assigned to user groups or to individual users of Confluence.

You need to be a space administrator to assign space permissions.

These are the different permissions that can be assigned at the space level:

- **View:** user can view this space's content, including the space's details, and its pages and news items (blog posts)
- **Pages:**
  - Create - user may create and edit pages in this space.
  - Export - user may export pages in this space.
  - Restrict - user may apply page level permissions.
  - Remove - user may remove pages in this space.
- **News** (i.e. blog posts):
  - Create - user may post news items in this space.
  - Remove - user may remove news items in this space.
- **Comments:**
  - Create - user may make comments in this space.
  - Remove - user may remove comments from this space.
- **Attachments:**
  - Create - user may add attachments in this space.
  - Remove - user may remove attachments from this space.
- **Mail:**
  - Remove - user may delete individual mail items.
- **Space:**
  - Export - user may export content from this space.
  - Admin - user has administrative permissions over this space.

Warning
If you deny all administrative access to a space by mistake, so that nobody has access to administer the space any more, you will need to ask someone in the confluence-administrators group to fix the permissions for you.

To access the space permissions,

1. Click the 'Browse Space' link for the space. This is located at the top of every page and beside the space link on the dashboard.
2. Go to the 'Space Admin' tab. This tab is only displayed if you are a space administrator.
3. Click the 'Permissions' link in the left-hand panel under the heading 'Security'. This will display the space's current permissions assigned to the different groups and users.
4. Click the 'Edit Permissions' button.
5. The 'Edit Space Permissions' screen appears, as shown below.

To assign space permissions to groups,
To assign space permissions to users,

1. Access the 'Edit Space Permissions' screen as described above.
   The **Individual Users** section shows a list of users who already have permissions to access the site.
   - To assign permissions, check the box next to the relevant user, for each of the required permissions.
   - To deny a permission, uncheck the relevant box.
   - To add a new user to the list, type the username into the text box labelled 'Grant browse permission to' and click the 'Add' button. The user will appear in the list of users, with 'View' permission assigned, and you can then add more permissions if necessary.
   - To search for a user:
     - Click the icon.
     - The 'User Search' window will appear. You can read more about searching for users.
     - Check the boxes to select the required user(s).
     - Click the 'Select User(s)' button. The username(s) will appear in the 'Grant browse permission to' text box.
     - Click the 'Add' button.

2. Click 'Save All' to apply the permissions.

To assign space permissions to anonymous users,

1. Access the 'Edit Space Permissions' screen as described above. The **Anonymous Access** section shows the space permissions granted to all anonymous users of the site.
   - To assign permissions, check the box for the required permission.
   - To deny a permission, uncheck the relevant box.

2. Click 'Save All' to apply the permissions.

You cannot grant space 'Admin' rights or Page 'Restrict' rights to anonymous users.

**Screenshot: Edit space permissions**
You can edit the current space permissions here. Permissions can be granted to specific users or groups. You can also grant permissions to anonymous users. Anonymous users refers to all users that are not logged in. For information about the individual permissions that can be assigned, please see the permissions guide.

**Groups**

These groups have access to this space in Confluence - that means they can view the pages, comments and news items within it.

**Individual Users**

These individual users have access to this space in Confluence - that means they can each view the pages, comments and news items within it.

**Anonymous Access**

When a user is using Confluence while not logged in, they are using it anonymously. For example: Enabling anonymous 'commenting' permission, allows non-logged-in users to make comments in this space.

---

**About some error messages you may see**

In Confluence 2.7.2 and later, Confluence will let you know if there is a problem with some permissions. In rare situations, you may see the following error messages below a permission:

- **'User/Group not found'** — This message may appear if your LDAP repository is unavailable, or if the user/group has been deleted after the permission was created.
- **'Case incorrect. Correct case is: xxxxx'** — This message may appear if the upper/lower case in the permission does not match the case of the username or group name. If you see a number of occurrences of this message, you should consider running the routine supplied to fix the problem.

**Revoking Space Permissions**

You need to be a space administrator to remove or revoke space permissions.

To revoke space permissions,
1. Click on the 'Browse Space' link for that space. This is located at the top of every page and beside the space link on the dashboard.

2. Go to the tab 'Space Admin'. This tab is only displayed if you are a space administrator.

3. Click on the 'Permissions' link in the left panel under the heading 'Security'. This will display the space's current permissions assigned to the different groups and users.

4. Click 'Edit permissions'. This will bring up a new screen. See screenshot.

5. Uncheck the permissions you wish to revoke. Removing the 'View' permission for a user or group will remove all access to that space for the user or group.

6. Click 'Save All' to apply the permissions.

Screenshot: Assigning Space Permissions

Groups
These groups have access to this space in Confluence - that means they can view the pages, comments and news items within it.

Take me back to Confluence User Guide

Viewing Space Permissions
You need to be a space administrator to view the permissions assigned for a space.

To view the permissions assigned for a space,

1. Click the 'Browse Space' link for that space.
2. Click the 'Space Admin' tab. This tab is only displayed if you are a space administrator.
3. Click the 'Permissions' link in the left-hand panel under the 'Security' heading. This will display all the permissions assigned to the different groups and users for this space.

Below is an example. The ticks in the boxes indicate which permissions have been granted. The crosses indicate which permissions have been denied.
In Confluence 2.7.2 and later, Confluence will let you know if there is a problem with some permissions. In rare situations, you may see the following error messages below a permission:

- **'User/Group not found'** — This message may appear if your LDAP repository is unavailable, or if the user/group has been deleted after the permission was created.
- **'Case incorrect. Correct case is: xxxxxx'** — This message may appear if the upper/lower case in the permission does not match the case of the username or group name. If you see a number of occurrences of this message, you should consider running the routine supplied to fix the problem.

### Users and Groups

A user is any individual who accesses Confluence.

New users are created by a Confluence administrator via the Administration Console. See Searching For and Managing Users for more information.

A Confluence administrator can also group users together into user groups for more convenient administration. This means that any permissions you assign at the site, space and page levels can be assigned to a whole group. A user in one of these groups will automatically be granted all permissions granted to the group.

There are two special groups in Confluence:

- **Confluence-Administrators** - This is a ‘super-group’ and a user from this group has permission to do anything in the site regardless
Confluence 3.0 Documentation

of any other setting.

- **Confluence-Users** - This is the default group into which all new users are assigned. Permissions you assign to this group will be assigned to all newly signed-up users of Confluence.

**Anonymous Users**

Confluence treats all users who do not log in when they access Confluence as being 'Anonymous'. Administrators can assign permissions to this group separately.

**Overlapping group and user permissions**

When a user is assigned more than one permission, the most powerful permission will prevail.

Further explanation:

- A user may be assigned a permission specifically to their username. They may also be assigned a permission by belonging to a group, or even several groups.
- The user will then be able to perform all functions assigned to them.
- So if a user is allowed to do something over and above what the group can do, the user will be able to do it. And if the group is allowed to do something over and above the specific permissions granted to the user, the user will still be able to do it.

**RELATED TOPICS**

- Space Permissions Overview
- Viewing Space Permissions
- Assigning Space Permissions
- Page Permissions
- The Administrator's Guide to User Management in Confluence

Take me back to Confluence User Guide

**Searching for Users**

This page tells you how to use the 'User Search' window, which appears when you click a 'Choose Users' link or a user search icon on a Confluence page.

**On this page:**

- Accessing the User Search
- Using the Simple User Search
- Using the Advanced User Search
- Searching for Users in One or More Groups
- Selecting One or More Users
- More about the User Search

**Accessing the User Search**

To access the 'User Search' window,

1. Click the user search link or icon when you are performing one of the following actions:
   - When setting page restrictions, click the 'Choose users' link.
   - When assigning space permissions, click the icon in the users section.
   - When adding members to a group, click the icon.
2. The simple 'User Search' window will appear, as shown below.

**Using the Simple User Search**

**Crowd and the User Search**

If you are using Atlassian's Crowd for user management, you will need Crowd 1.5.1 or later to use the 'Simple' option in the user search. If your version of Crowd does not support the simple user search, you will see only the 'Advanced' search form.

To search via the simple user search,
1. Select the 'User' tab on the 'User Search' screen. (See above for instructions on accessing the screen.)
2. If the 'Simple' link is showing, click it. (If you see the 'Advanced' link and no 'Simple' link, then you're fine. The simple search is already active.)
3. The simple user search screen will appear, as shown below.
4. Type some information about the user into the 'Search' textbox. You can type all or part of their username, full name or email address.
5. Click the 'Search' button.
6. Confluence will return a list of matching users. See below for instructions on selecting one or more users.

![Screenshot: Simple user search](image)

**Using the Advanced User Search**

The advanced user search allows you to specify the field in which your search term appears, i.e. username, full name or email address. You may find this useful if you need to limit the number of users appearing in the search results.

To search via the advanced user search,

1. Select the 'User' tab on the 'User Search' screen. (See above for instructions on accessing the screen.)
2. If the 'Advanced' link is showing, click it. (If you see the 'Simple' link and no 'Advanced' link, then you're fine. The advanced search is already active.)
3. The advanced user search screen will appear, as shown below.
4. Complete one or more of the following fields:
   - **User Name** — Enter all or part of the person's username i.e. their login id, e.g. 'joe', or 'bloggs'.
   - **Full Name** — Enter all or part of the person's name, e.g. 'joe bloggs', or 'bloggs', or 'joe'.
   - **E-Mail** — Enter all or part of the person's email address, e.g. 'acme'
5. Click the 'Search' button.
6. Confluence will return a list of matching users. See below for instructions on selecting one or more users.

![Screenshot: Advanced user search](image)

**Searching for Users in One or More Groups**

You can also list the users who appear in a particular group or in a set of groups.

To search for users in a particular group,
1. Select the 'Membership' tab on the 'User Search' screen. (See above for instructions on accessing the screen.)
2. The 'Group Membership' search screen will appear, as shown below.
3. Type all or part of a group name into the 'Search' textbox.
4. Click the 'Search' button.
5. Confluence will return a list of users belonging to any groups which match your search term.
   - In the example screenshot below, we entered a group name of 'dev'. The search results show all users belonging to the group 'developers' and all users belonging to the group 'developers-mates'.
6. Now you can select one or more users, as described below.

**Selecting One or More Users**

After searching for users and receiving a list of names from Confluence, as described above, you can now select the user(s) you need.

**To select one or more users,**

1. Click the box next to the username(s) to select or unselect one or more users.
   - You can click 'Check All' to select or unselect all users.
2. Click the 'Select User(s)' button.
3. The 'User Search' window will close and the selected users will appear on the screen which you were using before you accessed the user search.
More about the User Search

Case Sensitivity

The search is not case sensitive. You can enter either upper- or lower-case text, and it will make no difference to the search results.

Wild Cards

The search allows the asterisk as a wild card, but you do not need to use it. The search results will be the same whether you use a wild card or not. The wildcard functionality remains available for compatibility with older versions of Confluence.

You can use an asterisk "*" as a wild card when entering user details. The search will allow one or more characters to match the asterisk. For example:

- Enter jon* to retrieve all the following: 'Jon Bloggs', 'Jon Smith' and 'Jonathan Jones', etc
- Enter *bloggs to retrieve all the following: 'James Jon Bloggs', 'Joe Bloggs', 'Jon Bloggs' and 'Richard Bloggs', etc
- Enter *jon* to retrieve all the following: 'James Jon Bloggs', 'Jon Bloggs', 'Jon Smith' and 'Jonathan Jones', etc

RELATED TOPICS

Setting a Page’s Restrictions
Assigning Space Permissions
Adding or Removing Users in Groups

Take me back to Confluence User Guide

Viewing Restricted Pages

Restricted pages are pages that have 'View' or 'Edit' restrictions applied to them through page-level permissioning.

You need to be a space administrator to view the list of restricted pages in a space.

To view restricted pages,

1. Click on the 'Browse Space' link for the space. This is located at the top of every page or beside the space link on the dashboard.
2. Go to the 'Space Admin' tab. This tab is only displayed if you are a space administrator.
3. Click on 'Restricted Pages' in the left panel under the heading 'Security'.
   A list of all restricted pages in the space is displayed.
4. Click on the 'lock' icon to remove restrictions for the page.

Here’s an example:
Confluence Notation Guide Overview

Confluence pages are stored internally in a simple content-formatting language called Wiki Markup, based on Textile.

The Wiki Markup Editor allows you to edit Confluence pages directly in wiki markup language. This has the advantage of being faster than the Rich Text Editor for some formatting tasks.

A quick notation guide, Notation Help, appears beside the edit screen when you choose the Wiki Markup edit tab. You can then click the full notation guide link in the help window to view the full Notation Guide. This shows you the entire list of formatting and other complex operations that Confluence's notation permits, along with the markup detailing how to perform them.

Try it now

Because wiki markup is designed to be simple to learn, the quickest way to learn wiki markup is to edit an existing page, switch to the wiki markup editor and experiment.

Below are some links to more information on wiki markup editing:

- Full Notation Guide
- Working with Headings
- Working with Text Effects
- Working with Text Breaks
- Working with Links
- Working with Anchors
- Working with Images
- Working with Lists
- Working with Tables
- Working with Macros
- Confluence Emoticons

What does the Notation Guide contain and why is it not part of the Confluence User Guide?

The Confluence Notation Guide is included as part of the Confluence code and is dynamically generated when you view it. Its contents depend upon:

- the macro plugins available in the Confluence installation
- the documentation included by the plugin developer for the installed version of the plugin.

If you view the Full Notation Guide from the Atlassian Confluence site, you will see the information for the macro plugins currently installed on this site. If you view the Full Notation Guide from your own Confluence instance, you will see information for the macro plugins installed on your site.

The plugin developer writes the help file and includes it in the macro code.

Examples of Markup

Here's a short example of some typical markup:

| What you type | What you get |
Confluence Markup

Ideally, the markup should be *readable* and even **clearly understandable** when you are editing it. Inserting formatting should require few keystrokes, and little thought. After all, we want people to be concentrating on the words, not on where the angle-brackets should go.

- Kinds of Markup
  - Text Effects
  - Headings
  - Text Breaks
  - Links
  - Other

Here, in comparison, is how that would look if you had to edit the page in HTML:

```html
<h4>Confluence Markup</h4>
<p>Ideally, the markup should be <em>readable</em> and even <strong>clearly understandable</strong> when you are editing it. Inserting formatting should require few keystrokes, and little thought.</p>
<p>After all, we want people to be concentrating on the words, not on where the angle-brackets should go.</p>
<ul>
  <li>Kinds of Markup</li>
  <ul>
    <li>Text Effects</li>
    <li>Headings</li>
    <li>Text Breaks</li>
    <li>Links</li>
    <li>Other</li>
  </ul>
</ul>
```

Confluence Emoticons

Emoticons are little images you can easily use in a Confluence page. They use a simple wiki markup as shown below, or you can insert them using the Rich Text editor.

Graphical emoticons (smileys).

<table>
<thead>
<tr>
<th>Notation</th>
<th>Image</th>
</tr>
</thead>
<tbody>
<tr>
<td>:)</td>
<td>😊</td>
</tr>
</tbody>
</table>
Form Field Markup for Templates

Templates are written in the same notation as other pages in Confluence with special markup to insert form fields. When a user creates a page using a template that contains form fields, the user will be prompted to key in data. The data will be captured and stored in the new page.

Here are the three kinds of form fields supported and the markup to create them:

<table>
<thead>
<tr>
<th>Text field</th>
<th>Creates a text input field for a variable called VAR.</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>@VAR@</code></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Text area</th>
<th>Creates a 5 x 10 text-area for a variable called VAR.</th>
</tr>
</thead>
<tbody>
<tr>
<td>`@VAR</td>
<td>textarea(5,10)@`</td>
</tr>
</tbody>
</table>
Drop down menu

```@VAR|list(one,two,three,four)@
```

Creates a drop-down box containing the values "one", "two", "three" and "four".

**Note:** The values in the drop-down list can only contain letters, numbers and underscores.

The dropdown list values cannot include:

- special characters, such as `&`
- punctuation marks, such as `:`
- brackets, such as `)`

Every input field must have a unique name. If you have more than one text input field in the same template with the same name, Confluence will make sure that they all end up with the same value (This is useful if you need the same information in more than one place in the page).

For an example, please see Adding a Template.

**Warning**

There must be no spaces between the @-signs in the markup. This means you can't have items in your drop-down lists that contain spaces.

---

**Improved Markup**

The above formatting is the basic markup bundled with Confluence, but two plugins expand on this markup to provide greater functionality. Links to these plugins and a comparison can be found in the Working with Templates Overview.

---

**Working with Headings**

You can use Confluence Notation or the Rich Text editor to create headers.

Creating a header is easy. Simply place "hn." at the start of your line (where n can be a number from 1-6).

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>h1. Biggest heading</td>
<td>Biggest heading</td>
</tr>
<tr>
<td>h2. Bigger heading</td>
<td>Bigger heading</td>
</tr>
<tr>
<td>h3. Big heading</td>
<td>Big heading</td>
</tr>
<tr>
<td>h4. Normal heading</td>
<td>Normal heading</td>
</tr>
<tr>
<td>h5. Small heading</td>
<td>Small heading</td>
</tr>
<tr>
<td>h6. Smallest heading</td>
<td>Smallest heading</td>
</tr>
</tbody>
</table>
Note that Confluence treats all headings as anchors.

Working with Text Effects
Working with Macros

Take me back to Confluence User Guide

**Working with Lists**

Confluence allows you to create bulleted or numbered lists, and is flexible enough to allow a combination of the two lists.

1. If you need to separate the text within lists using line breaks, make sure you do so using a double slash (/\). Empty lines may disrupt the list.

**Simple lists**

Use the hyphen (-) to create simple lists.
Make sure there is a space between the hyphen and your text.

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>- somebulletpoints</td>
<td>• somebulletpoints</td>
</tr>
</tbody>
</table>

**Bulleted lists**

Use the asterisk (*) to create bullets. For each subsequent level, add an extra asterisk.
Make sure there is a space between the asterisk and your text.

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>* somebulletpoints</td>
<td>• somebulletpoints</td>
</tr>
</tbody>
</table>

**Numbered lists**

Use the hash (#) to create numbered lists.
Make sure there is a space between the hash and your text.

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td># a numberedlist</td>
<td>1. a numbered list</td>
</tr>
</tbody>
</table>

A second level of hashes will produce a sub-list, such as the **alphabetical** sub-list shown below.

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td># a numberedlist</td>
<td>1. a numbered list</td>
</tr>
<tr>
<td># b numberedlist</td>
<td>2. b numbered list</td>
</tr>
<tr>
<td># c numberedlist</td>
<td>3. c numbered list</td>
</tr>
</tbody>
</table>
Try a third level of hashes to produce a sub-sub-list.

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
</table>
| `# Here's a sentence.  
## This is a sub-list point.  
### And a second sub-list point.  
# Here's another sentence.` | `1. Here's a sentence.  
a. This is a sub-list point.  
b. And a second sub-list point.  
2. Here's another sentence.` |

In numbered lists as described above, the format of the 'number' displayed at each list level may be different, depending upon your browser and the style sheets installed on your Confluence instance. So in some cases, you may see letters (A, B, C, etc; or a, b, c, etc) or Roman numerals (i, ii, iii, etc) at different list levels.

**Mixed lists**

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
</table>
| `# Here  
## is  
* an  
# example  
* of  
# a  
# mixed  
# list` | `1. Here  
• is  
• an  
2. example  
• of  
• a  
3. mixed  
4. list` |
Working with Tables

You can use Confluence wiki markup or the Rich Text editor to create tables. Below are some guidelines on using wiki markup to create tables.

Confluence allows you to create two types of tables.

**Table Type 1**

Allows you to create a simple table with an optional header row. You cannot set the width of the columns in this table. Use double bars for a table heading row.

**What you need to type:**

```
<table>
<thead>
<tr>
<th>heading 1</th>
<th>heading 2</th>
<th>heading 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>cell A1</td>
<td>cell A2</td>
<td>cell A3</td>
</tr>
<tr>
<td>cell B1</td>
<td>cell B2</td>
<td>cell B3</td>
</tr>
</tbody>
</table>
```

**What you will get:**

<table>
<thead>
<tr>
<th>heading 1</th>
<th>heading 2</th>
<th>heading 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>cell A1</td>
<td>cell A2</td>
<td>cell A3</td>
</tr>
<tr>
<td>cell B1</td>
<td>cell B2</td>
<td>cell B3</td>
</tr>
</tbody>
</table>

Currently, Confluence does not support nested tables.

You can also use a vertical header.

**What you need to type:**

```
| heading 1 |  |  |
|-----------| |  |
|           |  |  |
|           | col A1| col A2| col A3 |
|           | col B1| col B2| col B3 |
```

**What you will get:**

<table>
<thead>
<tr>
<th>heading 1</th>
<th>col A1</th>
<th>col A2</th>
<th>col A3</th>
</tr>
</thead>
<tbody>
<tr>
<td>heading 2</td>
<td>col B1</td>
<td>col B2</td>
<td>col B3</td>
</tr>
</tbody>
</table>

**Table Type 2**

This method allows you to specify the width of the columns in the table.

**What you need to type**
What you will get

Text for this column goes here. This is the smaller column with a width of only 30%.

Text for this column goes here. This is the larger column with a width of 70%.

For more details please see the Column Macro and the Section Macro.

Advanced Formatting

Colour and Other Formatting

To add colour and other formatting to your tables, you can use the Panel Macro within columns. More table-formatting options may be available if your Confluence administrator has installed additional macros.

Lists

Here's an example of how to embed lists in a table:

What you need to type

<table>
<thead>
<tr>
<th>Heading 1</th>
<th>Heading 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>* Item 1</td>
<td>1. Item 1</td>
</tr>
<tr>
<td>* Item 2</td>
<td>2. Item 2</td>
</tr>
<tr>
<td>* Item 3</td>
<td>3. Item 3</td>
</tr>
</tbody>
</table>

What you will get

<table>
<thead>
<tr>
<th>Heading 1</th>
<th>Heading 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>* Item 1</td>
<td>1. Item 1</td>
</tr>
<tr>
<td>* Item 2</td>
<td>2. Item 2</td>
</tr>
<tr>
<td>* Item 3</td>
<td>3. Item 3</td>
</tr>
</tbody>
</table>

Working with Text Breaks

Paragraph break

When writing text in Confluence, a continuous line of text with two carriage returns at its end forms a paragraph in its own right. This is equivalent to a continuous line of text followed by a blank line.

When rendered into HTML, the result is a line of text ‘wrapped’ in a set of `<p>` tags.

Line break
Confluence also provides two options for forcing a line break within a paragraph of text either implicitly, by entering a single carriage return at its end or explicitly, by entering two consecutive backslashes (\).

When rendered into HTML, the result is a paragraph of text split into separate lines by `<br>` tags, wherever a forced line break appears.

For most purposes, explicit line breaks are not required because a single carriage return will often suffice. However, the examples below show how explicit line breaks can be used.

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>here is some text \ \ divided \ \ using line \ \ breaks</td>
<td>here is some text divided using line</td>
</tr>
<tr>
<td>This is a short list: * Point 1 \ * Point 2 \ \ \ \</td>
<td>This is a short list:</td>
</tr>
<tr>
<td>Text to go with point 1 \ Text to go with point 2 with a</td>
<td>• Point 1</td>
</tr>
<tr>
<td>break</td>
<td>• Text to go with point 1</td>
</tr>
<tr>
<td></td>
<td>• Point 2</td>
</tr>
<tr>
<td></td>
<td>• Text to go with point 2 with a break</td>
</tr>
</tbody>
</table>

If you wish to use multiple consecutive line breaks, each should be separated by a space character. For example, use `\ \` for two consecutive line breaks.

**Horizontal ruler**

Use four dashes (----) to create a horizontal ruler.

Make sure that the dashes are in a separate line from the text.

<table>
<thead>
<tr>
<th>What you need to type</th>
<th>What you will get</th>
</tr>
</thead>
<tbody>
<tr>
<td>here is some text ---- divided by a horizontal ruler</td>
<td>here is some text __________________</td>
</tr>
</tbody>
</table>

Working with Headings

Take me back to Confluence User Guide

**Rich Text Editor Overview**

The Rich Text editor provides users accustomed to HTML editing or other text editing applications, an easier and faster way to creating Confluence pages. It allows you to enter content as you would in a Word document, and apply formatting simply by clicking icons on a toolbar.

The 'Edit' screen lets you switch between 'Rich Text' and 'Wiki Markup' edit modes without losing the changes you've made; so you can use a combination of both while editing. For instance, you can use the rich text editor to change the text colour and then switch to Wiki Markup to create links.

You can also set the editor open either 'Wiki Markup' or 'Rich Text' by default, depending on your preference.

ℹ️ You can run the editor in a full-screen editing mode by clicking this icon at the far right of the toolbar.

### Rich Text Editing can be disabled

This option is enabled by default. Be aware however that site administrators can disable it. If it is disabled, a site administrator will need to enable it again from the Administration Console before you can start using the Rich Text editor.

**The Rich Text Editor**

![Rich Text Editor interface]

**Right-click Context Menu**

The Rich Text editor incorporates a right-click context menu that provides an additional mechanism for handling common editing actions available through the toolbar icons or keyboard shortcuts. For more information about the right-click context menu, refer to Rich Text-Right-Click Context Menu.
Enabling Rich Text Editing

Users have the option of using Confluence's Rich Text editor to create and edit page content. This option is enabled by default. If disabled, a site administrator will need to turn on 'Rich Text Editing' under 'General Configuration' on the Administration Console.

RELATED TOPICS

Making Rich Text or Wiki Markup Editing Default

Rich Text-Right-Click Context Menu

The Rich Text editor incorporates a right-click context menu that provides an additional mechanism for handling common editing actions, which are available through the toolbar icons or keyboard shortcuts.

The Rich Text Editor's right-click context menu

From the right-click context menu, you can insert or edit:

- A link
- An image
- A macro
- A table

Additional right-click context menu options to those shown above are available when editing links and tables.

Activating and deactivating the Right-Click Context Menu

By default, the right-click context menu may not be active. However, it can be activated using the 'Context Menu' icon in the toolbar.

To activate the right-click context menu,

Click the 'Context Menu' icon in the toolbar.

The 'Context Menu' icon changes to its activated state, indicating that the right-click context menu is active.

To deactivate the right-click context menu,
Click the active 'Context Menu' icon in the toolbar.

Alternatively, right-click within the Rich Text Editor's text editing area and click 'Disable context menu' from the context menu.

The 'Context Menu' icon changes to its deactivated state, indicating that the right-click context menu is not active.

Rich Text-Creating and removing a link

This page tells you how to add a link to your Confluence page. A link, or hyperlink, is a word or phrase which, when clicked, will direct the user to another web page or other location.

Wiki Markup mode and Rich Text editor

You can click the 'Insert Link' icon in either Wiki Markup mode or the Rich Text editor. The functionality described below is essentially the same for both editing modes.

On this page:

• Creating a link
• Removing a link

Creating a link

To create a new link,

1. Place your cursor at the point where you want to insert the link.
2. Click the 'Insert Link' icon in the toolbar.
   Alternatively, if the right-click context menu is enabled, you can right-click and choose 'Insert/Edit Link' from the context menu.
3. In the 'Link' text box, enter the URL (location) of the link.
   Use the tabs to help you find the URL:
   • Search – Search the spaces in your Confluence site for a particular term or phrase, then select your link location from the search results.
   • History – Select your link location from recently-visited pages.
   • Recently Modified – Select your link location from pages recently modified by yourself or other Confluence users.
   • External Link – Enter the URL of an external location.
   • Attachments – Select one of the attachments to the current page. You can also browse for a file and attach it to the page, then select it to create the link.
4. If you want your link to display specific words on the page, rather than the actual URL, enter the desired text in the 'Alias' text box.
5. If you want your link to display a short popup help tip, enter the desired text in the 'Tooltip' text box.
6. Click the 'OK' button to add the link.

You can also conveniently convert existing text into a link:

Instead of performing step one (above) you can highlight one or two or more consecutive words before proceeding directly to step two. By doing this, the words you selected will automatically appear in the 'Alias' text box.

To create a link via keyboard shortcut,

1. Press Ctrl-K (Internet Explorer in Windows). See Keyboard Shortcuts for key combinations used on other browsers and operating systems.
2. This will open up the 'Insert Link' window.
3. Follow the instructions in the sections above to complete the link creation.
Removing a link

You can easily remove a link using the right-click context menu.

To remove a link via the right-click context menu,

- Right-click over the link you want to remove and choose 'Unlink' from the context menu. The link will be removed from your text.
- The 'Unlink' item only appears on the right-click context menu when you right-click over an existing link.

**RELATED TOPICS**

Rich Text-Linking to a Page
Rich Text-Inserting an image
Rich Text-Linking to an Attachment

Take me back to the Confluence User Guide.

**Rich Text-Inserting an image**

This page tells you how to attach and insert an image, using the 'Insert Image' icon on the editor toolbar. You can also use Wiki Markup to insert an image.

**Wiki Markup mode and Rich Text editor**

You can click the 'Insert Image' icon in either Wiki Markup mode or the Rich Text editor. The functionality described below is basically the same for both editing modes.

To insert an image,
1. First, save your image somewhere on your computer or a network drive. For example, if your image is a screenshot you first need to save it. You can't paste the screenshot directly onto a Confluence page.

2. Click the 'Insert Image' icon in the toolbar. Alternatively, if the right-click context menu is enabled, you can right-click and choose 'Insert/Edit Image' from the context menu. The 'Insert Image' window will open.

3. If you have already attached images to the page, they will be listed in the 'Insert Image' window.

4. If you want to attach a new image:
   - Click the 'Browse' button.
   - Select your file from your computer or your network.
   - Click the 'Attach' button.

5. If you want to display an image attached to the page, click one of the attached images. The image name will appear in the 'Filename' text box.

6. If you want to display a remote image, enter the URL in the 'Filename' text box.

7. If you want the Confluence page to display a smaller version of your image rather than the full-size image, select the 'Thumbnail' check box. This will also hyperlink the image - if the user clicks the image, a new window will open displaying the full-size image.

8. If you want to control the placement of the image on the page, select a value from the 'Alignment' dropdown list. Available values are 'None' (i.e. default), 'Left', 'Centre' and 'Right'.

9. Click 'OK' to insert the image on the Confluence page.

To insert an image via keyboard shortcut,

1. Press Ctrl-M (Internet Explorer in Windows). See Keyboard Shortcuts for key combinations used on other browsers and operating systems.
2. This will open up the 'Insert Image' window.
3. Follow the instructions in the sections above to complete the image insertion.
1. Click 😊 on the toolbar. This will pop up the emoticons window.
2. Select the emoticon to insert it.

You can also insert emoticons by typing commonly-used character combinations. For example, the following code appears as an emoticon when the page is rendered.

This example creates this emoticon: 😊.

**Preventing Emoticons from Appearing**

To prevent Confluence from turning parts of text into emoticons, 'escape' the character sequence by inserting a `\` character.

For example, this character sequence contains an emoticon:

This example creates this in a rendered page: (-example_here😊).

To 'escape' the emoticon sequence, insert a slash as in the following example:

The characters will then appear exactly as typed.

Rich Text-Linking to an Attachment

This page tells you how to add a link which points to a file attached to your Confluence page. A link, or hyperlink, is a word or phrase which, when clicked, will open the attachment.
Wiki Markup mode and Rich Text editor

You can click the 'Insert Link' icon in either Wiki Markup mode or the Rich Text editor. The functionality described below is basically the same for both editing modes.

To link to an attachment,

1. Click the 'Insert Link' icon on the toolbar. This will open up the 'Insert Link' window.
2. Click the 'Attachments' tab. If any files are attached to your page, the attachments are listed here. Click the title of an attachment title to select it.
3. If you do not find the attachment you are looking for, you can also attach a new file from here. Click 'Browse' to select your file and click 'Attach', then select the file.
4. If you want your link to display specific words on the page, rather than the actual URL, enter the desired text in the 'Alias' text box.
5. If you want your link to display a short popup help tip, enter the desired text in the 'Tooltip' text box.
6. Click the 'OK' button to insert the link.

Read about creating new links for more information on the 'Insert Link' window.

Rich Text-Linking to a Page
To link to a page in Confluence,

1. While editing a page, click on the Rich Text Editor toolbar. This will open up the 'Insert Link' window.
2. Click on one of these tabs: 'History' or 'Recently Modified' to select the page you want to link to.
   Or:
   Do a Search for the page using the search facility and select a page from the search results.
3. Click 'OK'.

To link to a page outside Confluence,

1. While editing a page, click on the Rich Text Editor toolbar. This will open up the 'Insert Link' window.
2. Click on 'External Links' tab.
3. Enter the URL of the webpage in the text-entry field and click 'OK'.

To create a link via keyboard shortcut,

1. Press Ctrl-K (Internet Explorer in Windows). See Keyboard Shortcuts for key combinations used on other browsers and operating systems.
2. This will open up the 'Insert Link' window.
3. Follow the instructions in the sections above to complete the link creation.

To paste a link from your web browser,

1. In your web browser, click-and-drag to select the link text on the page.
2. Copy the selection to your clipboard (Ctrl-C or Edit > Copy in Windows).
3. Paste the selection into the Rich Text Editor (Ctrl-V or Edit > Paste in Windows).
4. The link’s original presentation will be replicated as closely as possible (the link’s name, the actual URL and some text formatting will be retained).
5. When you save the page, the link will be live.

Rich Text-Working with Tables

The rich text editor provides several table editing features.

On this page:
- Inserting a Table
- Table Toolbar Options
- Additional Right-Click Context Menu Table Options
  - Copying or Cutting and Pasting Rows
- Resizing a table using the mouse

Inserting a Table

To create a table,

1. Place your cursor at the point where you want to insert the table.
2. Click on the Rich Text Editor toolbar.
   Alternatively, if the right-click context menu is enabled, you can right-click and choose 'Insert Table' from the context menu.
   The 'Insert Table' window will open.
3. Enter the number of columns and rows for your table.
4. Select the check box if you want a heading style applied to the first row of the table.
5. Click 'OK'.

Table Toolbar Options

When you are editing a table and your cursor is placed within the table cell, the following options become available from the toolbar.
To do this with respect to the current table cell position | Click this
---|---
Insert an empty row above the current one | 
Insert an empty row below the current one | 
Remove the current row | 
Insert column to the left of the current one | 
Insert column to the right of the current one | 
Remove the current column | 
Remove the table | 

Additional Right-Click Context Menu Table Options

When you access the right-click context menu from within a table cell, additional options become available from this menu.

| To do this with respect to the current table cell position | Choose the following from the right-click context menu |
---|---|
Insert an empty row above the current one | Row > Insert row before |
Insert an empty row below the current one | Row > Insert row after |
Remove the current row | Row > Remove row |
Toggle between making the current row a heading or a normal row | Row > Heading row |
Insert column to the left of the current one | Column > Insert column before |
Insert column to the right of the current one | Column > Insert column after |
Remove the current column | Column > Remove column |
Remove the table | Remove table |

Copying or Cutting and Pasting Rows

The right-click context menu allows you to conveniently copy or cut and paste rows of a table. You can paste rows that you have cut or copied elsewhere within the same table or in another table.

⚠️ You cannot paste a row to another table in which the destination table has more columns than that of the table from which the row was cut or copied.

| To do this with respect to the current table cell position | Choose the following from the right-click context menu |
---|---|
Cut out the current row | Row > Cut row |
Copy the current row | Row > Copy row |
Insert the cut/copied row above the current one | Row > Paste row before ⭐ |
Insert the cut/copied row below the current one | Row > Paste row after ⭐ |

⭐ These options are only available if a row has been cut or copied first.

Screenshot: Right-Click Context Menu from within a Table Cell
Resizing a table using the mouse

1. Click anywhere inside the table to select it. The square (resize) boxes appear along the corners and edges of the table, as shown in the image above.
2. Click and hold down your mouse button over one of these resize boxes. While holding down your mouse button, drag the mouse to resize the table and release the mouse button when the table is at the required size.

Clicking a resize box along the edge of a table allows you to resize the table in one dimension, whereas clicking a resize box at the corner of a table allows you to resize the table in two dimensions.

Applying Text Formatting

To apply an effect, select the text and click one of the icons below, or use the shortcut key.

**Screenshot: Text Formatting Buttons on the Rich Text Editor Toolbar**

<table>
<thead>
<tr>
<th>To do this</th>
<th>Click this</th>
<th>Shortcut Key</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Bold</strong></td>
<td>B</td>
<td>Ctrl-b (on Windows, with Internet Explorer). <a href="#">See alternatives.</a></td>
</tr>
<tr>
<td><strong>Italics</strong></td>
<td>I</td>
<td>Ctrl-i (on Windows, with Internet Explorer). <a href="#">See alternatives.</a></td>
</tr>
<tr>
<td><strong>Underline</strong></td>
<td>U</td>
<td>Ctrl-u (on Windows, with Internet Explorer). <a href="#">See alternatives.</a></td>
</tr>
<tr>
<td><strong>Strike</strong></td>
<td>ABC</td>
<td>none</td>
</tr>
</tbody>
</table>

⚠️ There is currently no command for removing all formatting.

Applying Text Colours

To apply text colours, select the text you wish to change and then click this button ▪️ to select a text colour. A small colour-picker menu appears in-line.

**Screenshot: Picking Colours from the Rich Text Editor Toolbar**
Keyboard Shortcuts

Confluence provides the following keyboard shortcuts for English users. The letters may change in other languages.

Note that 'Alt' is the modifier key for Internet Explorer on Windows (except when using the Rich Text Editor — in that case it's 'Ctrl'). Other browsers have different modifier keys to activate the shortcuts; please see Modifier Keys below.

### All Screens

<table>
<thead>
<tr>
<th>Keystroke</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alt-Q</td>
<td>Quick search field</td>
</tr>
<tr>
<td>Alt-S</td>
<td>Submit (where a form is active)</td>
</tr>
</tbody>
</table>

### Rich Text Editor Screen

<table>
<thead>
<tr>
<th>Keystroke</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ctrl-(1-6)</td>
<td>Applies a heading style (of the number chosen) to the current line</td>
</tr>
<tr>
<td>Ctrl-M</td>
<td>Insert Image (opens insert image dialog)</td>
</tr>
<tr>
<td>Ctrl-K</td>
<td>Insert Link (opens insert link dialog)</td>
</tr>
<tr>
<td>Tab</td>
<td>Indents current line only in bullet lists &amp; numbered lists</td>
</tr>
<tr>
<td>Shift+Tab</td>
<td>'Outdents' current line only in bullet lists &amp; numbered lists</td>
</tr>
<tr>
<td>Ctrl-B</td>
<td>Makes the selected text <strong>bold</strong></td>
</tr>
<tr>
<td>Ctrl-I</td>
<td>Makes the selected text <em>italic</em></td>
</tr>
<tr>
<td>Ctrl-U</td>
<td>Makes the selected text <em>underlined</em></td>
</tr>
<tr>
<td>Ctrl-Z</td>
<td>Undo the most recent action</td>
</tr>
<tr>
<td>Ctrl-Y</td>
<td>Revert an action that was undone</td>
</tr>
</tbody>
</table>

Safari users please note: In the Rich Text Editor, the shortcut keys for **bold**, *italic* and *underlined* do not currently work. See CONF-13555. Cmd-B and Cmd-I currently toggle bold and italic formatting.

### Login Screen

<table>
<thead>
<tr>
<th>Keystroke</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alt-U</td>
<td>Username field</td>
</tr>
<tr>
<td>Alt-P</td>
<td>Password field</td>
</tr>
<tr>
<td>Alt-R</td>
<td>Check 'Remember Me'</td>
</tr>
</tbody>
</table>
View Screen

<table>
<thead>
<tr>
<th>Keystroke</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alt-A</td>
<td>Attachments View</td>
</tr>
<tr>
<td>Alt-E</td>
<td>Edit Page</td>
</tr>
<tr>
<td>Alt-I</td>
<td>Information View</td>
</tr>
<tr>
<td>Alt-M</td>
<td>Add Comment</td>
</tr>
</tbody>
</table>

Add Page Screen

<table>
<thead>
<tr>
<th>Keystroke</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alt-A</td>
<td>Add Page</td>
</tr>
<tr>
<td>Alt-P</td>
<td>Preview Page</td>
</tr>
<tr>
<td>Alt-S</td>
<td>Save button</td>
</tr>
</tbody>
</table>

Edit Page Screen

<table>
<thead>
<tr>
<th>Keystroke</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alt-U</td>
<td>Update Page</td>
</tr>
<tr>
<td>Alt-P</td>
<td>Preview Page</td>
</tr>
<tr>
<td>Alt-S</td>
<td>Save button</td>
</tr>
</tbody>
</table>

Modifier Keys

The modifier key will differ with each operating system and browser. For example, when running Firefox 2 on Windows, you will need to type 'Alt' + 'Shift' + 'E' to add a new page. The following table shows the modifier keys for the various combinations:

<table>
<thead>
<tr>
<th>Browser</th>
<th>Mac OSX</th>
<th>Windows</th>
<th>UNIX/Linux</th>
</tr>
</thead>
<tbody>
<tr>
<td>Internet Explorer</td>
<td>Ctrl</td>
<td>Alt</td>
<td>n/a</td>
</tr>
<tr>
<td>Mozilla Firefox 2</td>
<td>Ctrl</td>
<td>Alt + Shift</td>
<td>Alt + Shift</td>
</tr>
<tr>
<td>Mozilla Firefox 1</td>
<td>Ctrl</td>
<td>Alt</td>
<td>Alt</td>
</tr>
<tr>
<td>Opera</td>
<td>Shift + Esc</td>
<td>Shift + Esc</td>
<td>Shift + Esc</td>
</tr>
<tr>
<td>Safari</td>
<td>Ctrl</td>
<td>Ctrl</td>
<td>Ctrl</td>
</tr>
</tbody>
</table>

In the Rich Text Editor, the shortcut key modifier is different from the regular page shortcut key. For example in Safari, the general page shortcut key is 'Ctrl', but when using the Rich Text Editor, the shortcut key is 'Command'.

Note: In Internet Explorer, links will only be highlighted by shortcut keys; you will need to press Enter to proceed. Buttons, however, are activated through the shortcut.

Confluence Glossary

Administration Console

The Administration Console is the interface for the global administration of Confluence.

Only administrators can access the Administration Console.
The Confluence permission scheme allows the following main levels of administrator permissions:

- System Administrator – full administrative access to Confluence.
- Confluence Administrator – access to most of the Confluence administrative functions, but excluding those which could compromise the security of the Confluence system.

Please refer to the overview of global permissions for details of the functions which each level of administrator can perform.

**Breadcrumbs**

The breadcrumbs trace the path from the current page to the dashboard along the space's page-hierarchy.

The breadcrumbs in Confluence are listed at the top of every page.

**CamelCase**

CamelCase is a form of markup commonly used in wikis where words compounded together LikeThis without spaces are used to create links.

In Confluence, Camelcasing can be turned on from the Administration Console.

**Change Comment**

A change comment is a short description entered during the edit of a page to record the changes being made in the edit.

**Child Pages**

Creating child and parent pages is a means by which you can organize content on the site. A child page is a page that has a parent in any of the Confluence spaces.

A child can only have one parent.

**Comments**

A comment may be a remark, question, or any other additional information you wish to add to a page pertaining to the topic the page covers. You can comment on any page or news item in Confluence.

**Confluence Administrators**

The Confluence permission scheme allows the following main levels of administrator permissions:

- System Administrator – full administrative access to Confluence.
- Confluence Administrator – access to most of the Confluence administrative functions, but excluding those which could compromise the security of the Confluence system.

Please refer to the overview of global permissions for details of the functions which each level of administrator can perform.

**Confluence Markup**

This is the markup used to write and edit pages in Confluence. Based on Textile, the markup, when you become familiar with it, makes creating pages as easy as writing email.

**Custom Decorators**

Decorator files are used to define layouts in Confluence. They are vmd files and require knowledge of the language, Velocity, to edit.

**Dashboard**

The dashboard is the front page of a Confluence site. It provides an overview of the site, access to all spaces, and displays a list of the most recently updated content within them.

**Form Field Markup**

Form field markup is a specialised markup for creating form fields and is used when creating page templates.

**Global Administrators**
A global administrator is the same as a system administrator.

Global Spaces
Global spaces contain content on any theme or topic of your choice.
For more information about global spaces and personal spaces, see Working with Spaces Overview.

JIRA
JIRA is Atlassian's award winning Issue tracking and project management application.
Visit Atlassian's website to learn more about JIRA.

Labels
Labels are user-defined tag words assigned to pages to categorise content in Confluence.

Macros
A macro is a command wrapped inside curly braces {...} used to perform programmatic functions and generate more complex content structures in Confluence.

News Items
A news item may be a journal entry, status report or any other timely information pertaining to a space.

Notifications
A notification is an email message sent to you updating you of changes to pages and spaces you choose to ‘watch’.

Orphaned Pages
An orphaned page is a page without any incoming links.

Pages
Pages are the primary means of storing information in Confluence. They are the building blocks of spaces and are written in Confluence markup.

Page Family
Pages in Confluence can be organised into a hierarchy of parent and child pages. A parent and all its children comprise a page family. Confluence permits nested page families.

Parent Page
A parent page is a page that has one or more child pages. It may itself be a child of another page.

People Directory
The People Directory contains a list of all users in your Confluence site. Each user's name links to their personal space.

Permalink
A permalink is the url used to link to specific content items like comments.

Personal Spaces
Personal spaces belong to particular users, and rather than being listed on the Dashboard, are available from the People Directory.

For more information about global spaces and personal spaces, see Working with Spaces Overview.

## RSS Feeds

An RSS feed is a format for delivering summaries of regularly changing web content. RSS is read by RSS newsreader programs. You will need an RSS reader to subscribe to feeds within Confluence.

Confluence acts as an RSS reader for feeds from sites outside of Confluence.

## RSS Reader

An RSS reader is a specialised RSS program (also called aggregator) that displays the contents of RSS feeds for you. To subscribe to RSS feeds within Confluence, you will need an RSS reader.

## Site Administrators

The Confluence permission scheme allows two levels of administrator permissions:

- **System Administrator** – full administrative access to Confluence.
- **Confluence Administrator** – access to most of the Confluence administrative functions, but excluding those which could compromise the security of the Confluence system.

Please refer to the overview of global permissions for details of the functions which each level of administrator can perform.

## System Administrators

The Confluence permission scheme allows two levels of administrator permissions:

- **System Administrator** – full administrative access to Confluence.
- **Confluence Administrator** – access to most of the Confluence administrative functions, but excluding those which could compromise the security of the Confluence system.

Please refer to the overview of global permissions for details of the functions which each level of administrator can perform.

### Space Administrators

A space administrator is a user with the ‘Space Admin’ permission for the space. A user with this permission can perform a host of functions relating to the management of a space and has complete access to the space regardless of any other control settings or permissions.

Permissions for a space are only assigned and modified by space administrators.

## Spaces

A space is an area on your site into which you can group different content items together based on any theme of your choice. All content in Confluence is organised into spaces.

There are two types of spaces: **global spaces** and **personal spaces**.

## Templates

A template is a pre-defined page that can be used as a prototype when creating pages. Templates are useful for giving pages a common style or format.

## Themes

Themes are pre-defined ‘look and feel’ styles which are configured from the administration menu and can be applied across Confluence or to a single space.

## Tiny links

A tiny link is the shortened url of a page which is useful when sending links to the page, for example, via email.

## Trackback
Trackback is a mechanism by which two sites can stay informed each time one site refers to the other by means of trackback 'pings'. In Confluence, Trackback is enabled from the Administration Console.

**Trackback Autodiscovery**

Trackback autodiscovery is a block of code that can be placed in a web-page to describe where trackback pings should be sent for that page. You can read the technical specification for autodiscovery here.

When Trackback is enabled, Confluence uses Trackback Autodiscovery to ping pages that are linked to, and to advertise its own pages as being able to receive pings.

**Undefined Links**

An undefined link is a link to a page that has not yet been created. Clicking on the page link allows you create the page.

**User Profile**

Every user account in Confluence is linked to a profile that contains user related information and options to configuring user preferences.

**Watching a Page**

When you watch a page, you are sent an email notification whenever that page has been modified.

**Watching a Space**

When you watch a space, you are sent an email notification whenever content has been added or modified in that space.

**Wiki**

Pioneered by Ward Cunningham, and named after the Hawaiian word for 'quick', a wiki is a website that makes it easy for anyone to contribute pages, and link them together.

**Troubleshooting Problems & Requesting Technical Support**

This document tells you how to troubleshoot problems and obtain technical support.

On this page:

- Troubleshooting a Problem
- Raising a Support Request
  - Raising a Support Ticket via the Confluence Support Request Form
  - Raising a Support Ticket via the Internet
- Logging a Bug Report
  - STEP 1. Check your Bug is Undiscovered
  - STEP 2. Confirm the Bug

**Troubleshooting a Problem**

If you have a problem with Confluence, please follow these steps:

1. If you are not a Confluence administrator, report your problem to the person in charge of your Confluence site and ask them to follow up on the issue.
2. Check our Frequently Asked Questions and our Knowledge Base for a solution to your problem.
3. Check the appropriate Confluence component in JIRA for known bugs.
4. If you are having problems configuring a feature, please take a look at the appropriate guides:
   - Confluence Installation Guide
   - Confluence Setup Guide
   - Administrators Guide
   - Configuration Guide
   - Database Configuration
5. If your issue is related to your database server, please refer to the documentation within the Known Issues For Supported Databases section.
6. If your issue is related to your application server, please refer to the documentation within the Installing the Confluence EAR-WAR Distribution section.
7. If your problem may be related to a plugin, you can enter Plugin Support Mode by briefly disabling the third party plugins.

If the above documentation does not solve your problem, you should create a support request. If you believe you are experiencing a bug, you may wish to create a bug report instead. Instructions for both are given below.

Raising a Support Request

Please check the plugin support

If you have a plugin-related issue, please check whether the plugin is supported by Atlassian. Visit the plugin's home page in the Extension space, and check for the 'Atlassian Supported' logo. If the plugin is not supported by Atlassian, you will need to contact the author directly.

There are two ways to raise a support request with Atlassian:

- Complete the support request form via your Confluence Administration Console. The advantage of this method is that Confluence will create the support ticket and attach the relevant system information and logs for you.
- Raise a support ticket directly via our support site on the internet.

Both methods are described below.

Raising a Support Ticket via the Confluence Support Request Form

This method is recommended, provided that SMTP email is set up on your Confluence instance.

The advantage of this method is that Confluence will create the support ticket and attach the relevant system information and logs for you.

You can also use this method to append system information to an existing support ticket.

1. Log in as a user with System Administrator or Confluence Administrator access.
2. Go to the Administration Console and click 'Support Request' under 'Administration' in the left-hand panel. The 'Raise Support Request' form will appear. Part of the form is shown below:
Support Request

Complete as much information as you can and then click submit to send your request to Atlassian Confluence Support.

Please be patient when submitting this form. It may take a few minutes depending on how long it takes to export your data to a file.

To: mail.confluence-support.requests@atlassian.com
CC: 

*Subject:*
Enter a one line summary of the problem.

*Description:*
Enter as much information as possible, including any error messages that are appearing and any steps the support team can take to reproduce the problem.

Existing Support Request:

To create a new support request, simply leave this field blank.

On To attach the information on this page to an existing support request, please enter the relevant issue key (e.g. CSP-12345).

**Contact Name:**

**Contact Email:**
tom@mycompany.com

**Contact Phone Number:**

Send  Cancel

The following is the additional information about your Confluence installation that will be sent along with the support request

<table>
<thead>
<tr>
<th>Environment Information</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>System Information</strong></td>
</tr>
<tr>
<td><strong>System Date</strong></td>
</tr>
<tr>
<td><strong>System Time</strong></td>
</tr>
<tr>
<td><strong>System Favourite Colour</strong></td>
</tr>
<tr>
<td><strong>Java Version</strong></td>
</tr>
</tbody>
</table>

3. Please provide as much information as possible, following these guidelines:

   - **‘To’** — This is an email address, named the Site Support Address and configured on the ‘General Configuration’ screen of your Confluence instance. It points to a JIRA instance (usually the Atlassian Support System) which is configured to receive and handle support requests by email.

   - **‘CC’** — Any email address(es) entered here will receive a copy of the support request, including all system information. You can enter more than one email address, separated by commas (e.g. joe@mycompany.com, sally@mycompany.com, jane@myothercompany.com).

   - **‘Subject’** — Enter a short and meaningful description of the problem.

   - **‘Description’** — Please enter as much information as possible, including any error messages that are appearing and any steps the support team can take to reproduce the problem.

   - **‘Existing Support Request’** — If you have previously raised a support request for the problem, please type the issue key here (e.g. CSP-12345). The information on this form will be appended to the existing support ticket.

   - **‘Contact Name’** — This will default to the name of the logged-in user.

   - **‘Contact Email’** — This will default to the email address of the logged-in user.

   - **‘Contact Phone Number’** — Please enter a telephone number where our support staff can reach you. Include international and city codes.

4. Click the ‘Send’ button.

5. Confluence will submit your request via email to the JIRA instance referenced by the ‘To’ email address on the form. If you do not already have a support account, Confluence will automatically request one for you. The submitted request will include all the system and environment information which you see on the support request form. It will also include a zipped copy of your Confluence log file. Refer to Working with Confluence Logs for information about the log files. JIRA will create a support ticket including the submitted information.

   **Log files can be very big** — it is possible that your email server may bounce the message if too large. With the default log4j configuration, the log file could be up to 20Mb in size. If you have customised the log settings, the maximum size could be much...
larger still. Please check whether the email message has been successfully sent, and consult your email administrator if you need special provisions for this email message.

6. Once you have submitted your support request, you will receive email updates about its progress. These emails will give you the support ticket number.

You can view the status of your support request and add any additional information required by visiting the Atlassian Support System at any time.

Raising a Support Ticket via the Internet

If your Confluence instance is not configured with SMTP mail or your Confluence instance is not running, you can raise a support ticket via the Atlassian Support System:

1. Create a zip of your Confluence logs to attach to the ticket. Refer to Working with Confluence Logs for information about the log files.
2. If your problem concerns user management or performance, please take a look at the additional requirements in Requesting External User Management Support or Requesting Performance Support.
3. If you do not already have a free Atlassian support account, create one here.
4. Log in to https://support.atlassian.com and select 'Create New Issue'.
5. Lodge a detailed description of your problem in the new support ticket.
6. Fill in all applicable information about your system, such as application server, database, etc.
7. If Confluence is running, go to the System Information screen in your Administration Console and copy the text of your system information into the ticket.
8. Once your ticket is lodged, wait to be notified by email of updates. If your production instance of Confluence is experiencing a critical problem, jump on Live Support and ask to have your issue reviewed immediately.

Logging a Bug Report

If you have found a bug, the easiest way to report it is to:

- Create numbered instructions on how to reproduce the bug.
- Log them as a support request.

The Atlassian support team will confirm your bug and lodge a bug report. Alternatively, you can log a bug report directly by confirming it according to these instructions:

STEP 1. Check your Bug is Undiscovered

1. Visit the Confluence bug tracker.
2. On the left under 'Text Search', type keywords for your problem into the Query field.
3. Click View and browse the summaries of the unresolved bugs. If any summary appears to describe your problem, check that the bug is not a match. If it is the same, you may wish to set a watch to be notified of updates or apply your vote towards having it resolved. If the problem does not already appear to have been logged, the next step is to confirm that the problem is a bug.

STEP 2. Confirm the Bug

Check the headings below. If one of the headings matches your problem, follow the instructions. If the problem does not fall under any category, follow the general instructions instead.

**Bug Affects Page Rendering or Content**

If you are having issues with Wiki Markup or page content not being shown as expected:

1. Create a new page in the Confluence Sandbox and try to duplicate the issue there.
2. If the problem recurs, log the new bug here.
3. Paste the web address (URL) of the Sandbox page along with the process you used to duplicate the problem.
4. If the issue does not occur, this is may not be a bug and you should log the problem as a support request instead.

**Bug Prevents Confluence from Starting**

Please lodge a support request with your configuration information and numbered instructions on how to reproduce the issue.

**Bug in External User Management**

Please lodge a support request with your user management configuration and numbered instructions on how to reproduce the bug.

**General Bug Confirmation**

1. If Confluence will not run, please log the problem as a support request instead.
2. Attempt to replicate the bug:
   - Download the latest version of Confluence Standalone.
   - Install the Standalone with the appropriate database and the demonstration site.
   - Try to duplicate your problem on the default setup with the demonstration data.
3. If the issue does not occur, you should open a support ticket.
4. If the issue does occur, log the new bug here along with the information you used to duplicate it.
5. Once your issue is lodged, wait to be notified by email of updates. If your production instance of Confluence is experiencing a critical problem, jump on Live Support and ask to have your issue reviewed immediately.

### 500 page

Sometimes it may be useful to include the result of the `500page.jsp`

```markdown

## Content Anonymiser for Data Backups

### Introduction

A Jira data anonymiser is also available.

Atlassian may request a copy of the `entities.xml` file from a customer's exported zip file, in order to diagnose database corruption, or to find a bug in Confluence.

If your data is confidential, you can run this program over your `entities.xml` file, removing all your data and leaving only the structure of the export.

### Usage

To run the anonymiser on your backup:

1. Download the anonymiser JAR.
2. Extract the `entities.xml` file from your zipped backup file to the same directory as the JAR.
3. Use the command prompt to go to the directory where all three files are located.
4. To create `cleaned.xml`, run the command:

```
java -jar confluence-export-cleaner-1.1-jar-with-dependencies.jar entities.xml cleaned.xml
```

### How it works

The Content Anonymiser application replaces all the text content in file `entities.xml` with 'x' characters. For example, the word "Atlassian" will be transformed to "xxxxxxxxx". The resulting `cleaned.xml` file is expected to have the same size of the original file.

This release of the export cleaner uses STX, a fast and efficient XML transformation technology. It should not require a lot of memory to run, even for a large backup.

### Development

For Atlassian developers:

- Source code
- Maven repository

---

## Editing or Deleting a Page That Won't Render

You may be able to access the edit page URL by hitting ctrl+e
If you have a page that you can't access (for example, due to an incompatible plugin that won't render a macro), you can delete or edit the page by manually entering the appropriate URL. The URL looks like this:

```
http://<baseurl>/pages/removepage.action?pageId=<pageID>
http://<baseurl>/pages/editpage.action?pageId=<pageID>
http://<baseurl>/pages/editblogpost.action?pageId=<pageID>
```

Substitute your page ID for the one you wish to delete. To determine the page ID, you may be able to access it from the edit page URL by hitting ctrl+e. If not, you can obtain this information from the database using an SQL query like this:

```
SELECT CONTENTID FROM content WHERE TITLE = '<pagename>' AND VERSION = '1';
```

This may return multiple results if there are pages with the same name in different spaces, so you may have to further determine the correct one.

To delete an attachment manually, you can use a URL like:

```
http://<baseurl>/pages/removeattachment.action?pageId=32787&fileName=harbour.jpg&version=1
```

To view the attachments on a page:

```
http://<baseurl>/pages/viewpageattachments.action?pageId=<pageId>
```

Get the page ID similarly.

To get the wiki markup from the database directly, try:

```
SELECT BODY FROM BODYCONTENT WHERE CONTENTID IN (SELECT CONTENTID FROM content WHERE TITLE = '<insert name of page or blog post>');
```

**Enabling detailed SQL logging**

Confluence uses the open source persistence framework Hibernate. This page tells you how to configure Confluence's logging to report individual SQL requests being sent to the database by Hibernate. It is useful for troubleshooting:

- XML site backups that fail to import
- Exceptions caused by an illegal database operation

Enable SQL logging via the Administration Console

Since the 2.7 release, you can also enable SQL logging at runtime via the Administration Console — read the instructions. This runtime option does not allow you to enable logging of SQL parameter values.

To enable detailed SQL logging in Confluence, you need to modify `log4j.properties`, located in `confluence/WEB-INF/classes`.

After you have enabled hibernate logging, please replicate the action that is causing the error in the first place. This is the best way to ensure that the Confluence log file contains relevant SQL logging.

If you require support assistance with a database related problem, it is advisable to enable detailed SQL logging before sending us the log files. This will assist us in determining what SQL queries were running during the reported problem.

If the entries mentioned below are not defined in the `log4j.properties` file, you can manually add the entries to the file in the 'Hibernate Logging' section.

**To Log SQL Queries**

Stop Confluence, then uncomment the following lines in `log4j.properties`:
## log hibernate prepared statements/SQL queries (equivalent to setting 'hibernate.show_sql' to 'true')
log4j.logger.net.sf.hibernate.SQL=DEBUG,confluencelog
log4j.additivity.net.sf.hibernate.SQL=false

### To Log SQL Queries with Parameters

Stop Confluence, then uncomment the following lines in `log4j.properties`:

```
## log hibernate prepared statement parameter values
log4j.logger.net.sf.hibernate.type=DEBUG,confluencelog
log4j.additivity.net.sf.hibernate.type=false
```

### To Disable Batched Updates for Simpler Debugging

Stop Confluence, then edit `databaseSubsystemContext.xml`:

- In Confluence 2.5.x and earlier, the `databaseSubsystemContext.xml` file is at
  `confluence/WEB-INF/classes/databaseSubsystemContext.xml`
- From Confluence 2.6.x, the `databaseSubsystemContext.xml` file is available in the `confluence-2.6.0.jar` file located in the `<confluence-install>/WEB-INF/lib` directory.

Uncomment the `<prop>` line in the following location:

```
<!-- it can be useful to disable batching during debugging, as HSQLDB doesn't report the exact
statement which fails in batch mode -->
<prop key="hibernate.jdbc.batch_size">0</prop>
```

If you are experiencing a problem, you should always create a support request before using Live Support.

**Generating a Thread Dump**

- Stack Traces and Security
- Generating a Thread DumpExternally when Confluence stops responding
- Generating a Thread Dump via the Administration Console
1. **Scheduling Thread Dumps via the Administration Console**

If Confluence is performing poorly, behaving unexpectedly or stops responding and you can generate a thread dump to help diagnose the cause of the problem. Furthermore, if you wish to contact Atlassian Support for assistance about it, you should include a thread dump in your support enquiry to help the Support team determine the cause of the problem.

A thread dump will show the state of each thread in the JVM, including a stack trace. Thread dumps are only useful if they are taken at the appropriate time. They normally need to be taken at or close to the time when the application is experiencing problems.

Information about what locks are being held and waited upon by a thread are not produced by Confluence’s Thread Dump tool. If you require this information, then generate a thread dump externally.

### Stack Traces and Security

To help debug support cases and provide legendary support, Confluence provides stack traces through the web interface when an error occurs. These stack traces include information about what Confluence was doing at the time, and some information about your deployment server.

Only non-personal information is supplied such as operating system and version and Java version. With proper network security, this is not enough information to be considered dangerous. No usernames or passwords are included.

### Generating a Thread Dump Externally when Confluence stops responding

If Confluence stops responding or you require information on locks being held and waited upon by threads, then use one of methods described in **Generating a Thread Dump Externally**.

### Generating a Thread Dump via the Administration Console

For Confluence 2.10.3 or below

This feature was introduced in Confluence 3.0. if you are using a prior version then please consult this documentation on Generating a Thread Dump Externally.

**For Confluence 2.10.3 or below**

This feature was introduced in Confluence 3.0. if you are using a prior version then please consult this documentation on Generating a Thread Dump Externally.

To generate a Thread Dump from the Administration Console,

1. Go to the Confluence ‘Administration Console’. To do this:
   - Open the ‘Browse’ menu and select ‘Confluence Admin’. The ‘Administration Console’ view will open.
   - Select ‘Thread Dump’ in the left-hand panel.
   - Click the ‘Generate Now’ button in the centre of the page. The output is displayed in a new text box that appears just below the button.
   - Copy the contents of the thread dump in the text box and save it to a text file.

**Screenshot: Example of a generated thread dump from the Confluence administration console**
Scheduling Thread Dumps via the Administration Console

If you were asked by Atlassian Technical Support to generate regular thread dumps, please set the Thread Dump Scheduler to take 2 to 3 thread dumps with a 30 seconds time interval in between so the Support team can observe any important patterns that may assist with the diagnosis of the problem. Attach the log file to the support ticket.

Example: Scheduling thread dumps from the Confluence administration console

<table>
<thead>
<tr>
<th>Schedule Thread Dump Execution</th>
</tr>
</thead>
<tbody>
<tr>
<td>The output will be written to your log file.</td>
</tr>
<tr>
<td><strong>Number of thread dumps to generate:</strong></td>
</tr>
<tr>
<td><strong>Pause between thread dumps:</strong></td>
</tr>
<tr>
<td><strong>Schedule Now</strong></td>
</tr>
</tbody>
</table>

Generating a Thread Dump Externally

If Confluence stops responding and you cannot access its integrated Generate Thread Dump feature, it is possible to create thread dumps outside the application. External thread dumps are also useful if you require information on locks being held or waited upon by threads.

Generating a Thread Dump on Windows

To take a thread dump from Windows:

2. Click Run for any security warnings
3. Under Process Id, select the ‘...’ button.
4. From the drop-down list, select the Confluence process. Users running Confluence Standalone, select the ‘Java (Tomcat) ...’ option. Users running Confluence WAR should select their application server process.
5. Under Process -> Properties, Ensure that the "Thread dump" and "Keep Remote Thread Running" is selected.
6. Select Process -> Thread Dump
7. Save the output to a file, eg ‘threaddump.log’

Alternatively, if you were asked by Atlassian technical support to create the thread dump, please take 2 to 3 thread dumps with a time interval in between (eg. 30 seconds) so we can see some patterns. Attach the log file to the support ticket.

Generating a Thread Dump on Linux, including Solaris and other Unixes

Find the process ID of the JVM and use the `ps` command to get list of all processes:

```
ps
```

```
kill -3 <pid>
```

Note: This will not kill your server (so long as you included the "-3" option, no space in between). The thread dump will be printed to Confluence's standard output (catalina.out).

Output

Standard logging for Confluence Stand-alone is sent to the `atlassian-confluence.log` in the confluence-home directory, not in the confluence-install directory. Thread dumps are an exception since they dump the threads of the entire application server - they'll appear in the catalina.out file in the application directory's logs folder. You can search for the term "thread dump" in the log file for the beginning of the dump. Submit this along with the atlassian-confluence.log in your support ticket.

Thread Dump Tools

- Samurai
- Thread Dump Analyzer TDA TDA 1.0 Final can be obtained from the [java.net](http://java.net)
**Plugin Support Mode**

Incompatible with Confluence Clustered
At this time, Plugin Support Mode will not work correctly in a Confluence cluster.

Beginning with Confluence version 2.9 the Plugin Repository Client now offers "Support Mode" for troubleshooting plugin-related issues. It will temporarily disable all unsupported plugins and re-enable them with a single click.

1. From Administration > Plugin Repository, choose the Admin tab.
2. Click "Enter Support Mode."

To re-enable the plugins, click the same link to restore the plugins to their previous state.

If you get errors when trying to re-enabled plugins, this is because some third-party plugins cannot be disabled and then re-enabled at runtime. Restart Confluence to restore your complete list of plugins.

**Profiling using the YourKit Plugin**

There is a plugin for Confluence 2.2 and later which allows easy profiling using the YourKit profiler. No license is required to generate a memory or CPU snapshot, but you will need at least an evaluation license to analyse the results.

JIRA also has a plugin to profile JIRA's CPU and memory usage with YourKit.

On this page:
- Configuring YourKit in your JVM
  - Windows Configuration
  - Linux/Mac OS X Configuration
- Performance Impact
- Installing the YourKit Plugin
- Why would I do this?
- Plugin Source Code

**Configuring YourKit in your JVM**

Download YourKit 6.0 for your platform and follow the installation instructions to install it.

⚠️ Note: YourKit version 7 is not compatible with the Confluence yourkit plugin.

The following instructions apply to Confluence Standalone and Tomcat installations with Sun JDK 1.5. They should be easily applicable to other application servers and JVMs, however. The YourKit documentation covers this in more detail.

**Windows Configuration**

On Windows, add to your PATH environment variable the bin/win32/ directory underneath the YourKit installation directory. For example, you might add "C:\Program Files\YourKit Java Profiler 6.0.12\bin\win32" to your PATH, via Control Panel, System, Advanced, Environment Variables.

To configure Confluence's JVM to use the YourKit agent, you need to add a parameter to JAVA_OPTS in the bin/setenv.bat file in your Confluence application directory. This file controls the startup parameters for Tomcat, so you'll need to restart it after making the changes.

Add the 'agentlib' parameter to the end like this:

```
set JAVA_OPTS=%JAVA_OPTS% -Xms128m -Xmx256m -agentlib:yjpagent
```

**Linux/Mac OS X Configuration**

On Unix-based systems, include the installation directory in the library path environment variable, as shown below:

- For the Mac: `export DYLD_LIBRARY_PATH=$DYLD_LIBRARY_PATH:/path/to/yourKitAgent`
- For other Unix-based systems: `export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:/path/to/yourKitAgent`

In general, to configure a Sun 1.5 JDK, you add the agentlib parameter:

```
java -agentlib:yjpagent ...
```

You can add this to Tomcat's bin/setenv.sh like this:
Performance Impact

Running YourKit can have detrimental effects on performance.

To minimize performance problems use the following modifications to the agentlib parameter:

```
-agentlib:yjpagent=disablecounts,disablealloc,disablej2ee
```

See also Profiling overhead: how to reduce or avoid in the YourKit documentation.

Installing the YourKit Plugin

Download the plugin and upload it into Confluence through the Administration, Plugins page.

A new menu option will appear under the 'Administration' heading. Click it and you should see the options to take a memory or CPU snapshot.

YourKit Profiling menu item

This profiler dump will be saved to a local temp directory, and the path shown once it is complete. For the CPU snapshot, this will take at least 30 seconds. For the memory snapshot, 10-15 seconds.

You can take either a memory or CPU snapshot

Why would I do this?

Analysing a profiler dump enables Atlassian Support (or you, if you are interested) to see exactly what is happening in your application: what classes are using the memory, what is using CPU and so on. This can help us debug tricky performance problems which would otherwise be impossible to analyse remotely.

Take a CPU snapshot if:

- Confluence is sometimes unresponsive
- Pages take a long time to load
- Confluence’s CPU usage is peaking.

Take a memory snapshot if:

- Confluence’s memory usage is higher than you expect
- You are getting OutOfMemoryError’s in your logs.
If you run into situations where Confluence is unresponsive and you are not able to trigger a memory snapshot, please ensure that you start Confluence with the \texttt{onexit=memory} parameter in the JVM options (as in the example below) and simply shut down Confluence. Before shutting down a memory snapshot will be created.

\begin{verbatim}
-agentlib:yjpagent=onexit=memory
\end{verbatim}

**Plugin Source Code**

The source code for this Confluence plugin is available from Subversion and browseable in Fisheye. The JAR produced by `mvn package` includes a copy of the YJP redistributable bundled in META-INF/lib/.

**Tips of the Trade**

Below are some links to external blog posts, videos and articles containing technical tips and instructions on setting up and using Confluence. This page presents an opportunity for customers and community authors to share information and experiences.

The references here are specific to Confluence wiki and are technical 'how to' guides written by bloggers who use Confluence. For general information on wiki comparisons, wiki adoption, best practices and business cases, please refer to the Atlassian website and to our evaluator resources.

Please be aware that these are external blogs and articles. Most of the links point to external sites, and some of the information is relevant to a specific release of Confluence. Atlassian provides these links because the information is useful and relevant at the time it was written. Please check carefully whether the information is still relevant when you read it, and whether it is relevant to your version of Confluence. Unless explicitly stated, Atlassian does not offer support for third-party extensions or plugins. The information in the linked blog posts has not been tested or reviewed by Atlassian. We recommend that you test all solutions on a test server before trying it on your production site.

Information For Evaluators

Useful reading for anyone new to our wiki:

Basics

- Confluence Evaluator Resources
- Example Sites From Customers
- Independent Reviews
What browsers are supported? I cannot see the Rich Text Editor in my browser

Confluence 3.0 is supported in and developed against the following browsers:

The currently supported browsers are:

- Microsoft Internet Explorer 6.0 and 7.0
- Mozilla Firefox 2.0.x and 3.0.x
- Safari 2.0 (no rich-text editing), 3.0 and 3.1

We recommend using the latest production-level versions of these browsers: Firefox 3, Safari 3, Internet Explorer 7. Newer browser versions tend to perform better and have fewer bugs. In particular we strongly suggest using IE7 instead of IE6.

Support for Internet Explorer 6

Confluence will support IE6 until the 13th of July, 2010, in line with Microsoft's Support Lifecycle policy. Confluence 3.0 and future versions through 2009 will continue to support IE6.

Other Browser Support Issues

Rich text editing is not available in Opera (or Safari 2.0) due to Confluence's use of the TinyMCE 2.0 rich text editor component. See CONF-6428 for more information.

Confluence tries to be as standard-compliant as possible, but we only test against released versions of the above browsers. Many other browsers will work fine due to Confluence's general adherence to web standards.

Reporting Issues

If you come across an issue in a supported browser, please raise a bug in Confluence's public issue tracker.

If you come across an issue in an unsupported browser, please raise an improvement request in the same place. If Confluence's compliance with standards can be improved to also fix this issue, we'll leave the issue open for consideration. Unfortunately, we will not be able to fix bugs in unsupported browsers where our markup is valid according to the relevant standard and the bug is due to a problem with the browser itself.

In general, we will not fix issues with pre-release versions of browsers.
