Getting started

Atlassian Stash is the on-premises Git repository management solution for enterprise teams. It allows everyone in your organisation to easily collaborate on your Git repositories.

This page provides an overview of how to install, set up and start using Stash.

System requirements

- Stash is a Java application, and relies on the Git distributed version control system (DVCS). See our Supported platforms page to find out about system requirements.

Download and install Stash

- Windows
- Mac
- Linux

Use Git

Stash is all about managing Git repositories. If you still need to install Git locally, see the Installing and upgrading Git page.

We have some information here to help get you up and running with Git:

- Git Tutorials and Training
- Basic Git commands
- Permanently authenticating with Git repositories
- Using SSH keys to secure Git operations
- Git resources

Work with projects

Stash manages related repositories as projects. Find out how to set up projects and give your teams access to those.

If you have existing projects that you want to manage in Stash, then you'll want to read Importing code from an existing project.

Integrate Stash with other Atlassian applications

As a first step, see JIRA integration for information about using Stash with JIRA. To link Stash with JIRA, see Configuring JIRA integration in the Setup Wizard.

If you want to see results from your continuous integration or build server in Stash, see Bamboo integration.

Read more about using Stash

You are looking at the Stash documentation. Browse using the tree in the panel on the left, or use the search at the top right.

Using Stash in the enterprise

Atlassian Stash is the Git code management solution for enterprise teams. It allows everyone in your organisation to easily collaborate on your Git repositories, while providing enterprise-grade support for:

- user authentication
- repository security
- integration with your existing databases and development environment.

This page describes best practice for using Stash in enterprise environments, that is with 500+ user licenses. Of course, much of this information is also applicable to other Stash installations.

On this page:

- Platform requirements for hosting Stash
- Performance considerations with Stash
- Setting up Stash in a production environment
- Administering Stash in a production environment

Platform requirements for hosting Stash

Although Stash can be run on Windows, Linux and Mac systems, for enterprise use we only recommend, and support, Linux. This recommendation is based on our own testing and experience with using Stash.

Please see the Supported platforms page for details of the supported versions of Java, external databases, web browsers and Git.

Performance considerations with Stash

In general, Stash is very stable and has low memory consumption. There are no scalability limits other than for Git hosting operations (clone in particular). We know this is the scalability limit of the product; the limit is proportional to the number of cores on the system.

As an example, data collected from an internal Stash instance indicate that for a team of approximately 50, with associated continuous integration infrastructure, we see a peak concurrency of 30 simultaneous clone operations and a mean of 2 simultaneous clone operations. We conservatively expect that a customer with similar usage patterns would be capable of supporting 1000 users on a machine with 40 cores and a supporting amount of ram. While we expect a peak concurrency larger than 40, Stash is designed to queue incoming requests so as to avoid overwhelming the server.

Please see Scaling Stash for more information about Stash performance and hardware requirements.

Setting up Stash in a production environment

When setting up Stash for a production or enterprise environment, please follow the instructions on the Installing Stash on Linux and Mac page. We highly recommend that you configure the following aspects:

Use an external database

- For production environments Stash should use an external database, rather than the embedded database. Set up your external DBMS (for example MySQL) before starting Stash for the first time. This allows you to connect Stash to that DBMS using the Setup Wizard that launches when you first run Stash. See Connecting Stash to an external database.

Connect to your existing user directory

- Connect Stash to your existing user directory (for example Active Directory). See External user directories
Secure the Stash home directory

- For production environments the Stash home directory should be secured against unauthorised access. See Stash home directory.

Secure Stash with HTTPS

- Access to Stash should be secured using HTTP over SSL, especially if your data is sensitive and Stash is exposed to the internet. See Securing Stash with HTTPS.

Enable SSH access to Git repositories

- Enable SSH access for your Stash users to Git repositories in Stash so that they can add their own SSH keys to Stash, and then use those SSH keys to secure Git operations between their computer and the Stash server. See Enabling SSH access to Git repositories in Stash.

Change the context path for Stash

- If you are running Stash behind a proxy, or you have another Atlassian application (or any Java web application), available at the same hostname and context path as Stash, then you should set a unique context path for Stash. See Moving Stash to a different context path.

Administering Stash in a production environment

Upgrading Stash

- For production environments we recommend that you test the Stash upgrade on a QA server before deploying to production. See the Stash upgrade guide.

Backups and recovery

- We highly recommend that you establish a data recovery plan that is aligned with your company’s policies. See Data recovery and backups for information about tools and backup strategies for Stash.

Logging

- Stash server logs can be found in <STASH_HOME>/log. Logs for the bundled Tomcat webserver can be found in <Stash installation directory>/log. See Stash debug logging.
- Stash displays recent audit events for each repository and project (only visible to Stash admins and system admins), and also creates full audit log files that can be found in the <Stash home directory>/audit/logs directory. Note that Stash has an upper limit to the number of log files it maintains, and deletes the oldest file when a new file is created – we recommend an automated backup of log files. See Audit logging in Stash.

Supported platforms

This page lists the supported platforms for Stash 2.12.x.

See Integrating Stash with Atlassian applications for information about supported versions of JIRA.

- ❌ Java 8 is not supported and is an outstanding feature request.
- ❗️ Support for Java 6 is now deprecated. Stash 3.0+ will require Java 7. If you are using Java 6, Stash requires at least 1.6.0-4 (See STASH-3708).
- Stash only requires the Java JRE, not the...
For Oracle Java, we recommend using Server JRE 7, which you can download from the Oracle website.

For OpenJDK, download and install instructions for Linux flavors are at http://openjdk.java.net/install/.

Once Java is installed, you will need to set the JAVA_HOME environment variable, pointing to the Java root directory. See Installing Stash on Windows or Installing Stash on Linux and Mac for details.

Pre-installed Java on some AWS EC2 Linux instances might be installed with a subset of features. See SSH server fails to start on AWS EC2 instance for more information.

- Stash is a pure Java application and should run on any platform, provided all the Java requirements are satisfied.
- In production environments Stash should be run from a dedicated user account.
- Although Stash can be run in virtualised environments, Atlassian is not yet able to provide technical support for performance-related problems in a virtualised environment. If you do chose to run Stash in a virtual machine, please ensure that you choose a VM with good IO throughput and sufficient free memory. See hardware requirements below.

- Please see connecting Stash to an external database.
- ◯ MySQL 5.6.15 and earlier: Note that Stash does not support versions of MySQL 5.6 earlier than 5.6.16, because of bugs in its query optimizer (#68424, #69005). See Connecting Stash to MySQL for more information.
- ◯ MySQL 5.7+ is not supported.

## Hardware requirements

Stash needs a minimum of 720 MB of free memory to start up. Additional memory is required to support Git operations, depending on the number and frequency of Git operations and the number of users. See [Scaling Stash](#) for further discussion of hardware requirements.

**Notes:**

Deploying multiple Atlassian applications in a single Tomcat container is **not supported**. We do not test this configuration and upgrading any of the applications (even for point releases) is likely to break it.

Finally, we recommend not deploying *any other applications* to the same Tomcat container that runs Stash, especially if these other applications have large memory requirements or require additional libraries in Tomcat's `lib` subdirectory.

## Installing Stash on Windows

*Created in 2014 by Atlassian. Licensed under a Creative Commons Attribution 2.5 Australia License.*
Hey! We’re going to install Stash on Windows. There are a few steps, but we think you’ll really like Stash once it’s up and running.

If you are installing Stash for production or enterprise use, first check the additional steps at the bottom of this page and read Using Stash in the enterprise.

1. Check supported platforms

Better check the Supported platforms page first; it lists the application servers, databases, operating systems, web browsers and Java versions that we have tested Stash with and recommend.

Atlassian only officially supports Stash running on x86 hardware and 64-bit derivatives of x86 hardware.

Cygwin Git is not supported. No internal testing is done on that platform, and many aspects of Stash’s functionality (pull requests and forks among them) have known issues. When running Stash on Windows, always use msysGit.

Download latest version

2. Check your version of Java

In a command prompt, run this:

```
java -version
```

The version of Java should be 1.7.x (Java 1.8 is not supported yet).

If you don’t see Java 1.7.x then get Java...

Download Java Server JRE from Oracle’s website, and install it (note that Java 1.8 is not supported by Stash yet).

Now try running `java -version` again to check the installation. The version of Java should be 1.7.x.

3. Check that Windows can find Java

Stash uses the JAVA_HOME environment variable to find Java. To check that, in a command prompt, run:

```
echo %JAVA_HOME%
```

You should see a path to the root directory of the Java installation. When running Stash on Windows, unlike Linux or Unix, JAVA_HOME paths with spaces are just fine.

If you don’t see a path...

If you don’t see a path, or if you just see %JAVA_HOME%, then set JAVA_HOME as follows:
Windows Server 2003 R2 ...

Stage 1. Locate the JRE Installation Directory

If you already know the installation path for the Java Runtime Environment, go to Stage 2 below. Otherwise, find the installation path by following these instructions:

1. If you didn't change the installation path for the Java Runtime Environment during installation, it will be in a directory under C:\Program Files\Java. Using Explorer, open the directory C:\Program Files\Java.
2. Inside that path will be one or more subdirectories such as C:\Program Files\Java\jre7.

Stage 2. Set the JAVA_HOME Variable

Once you have identified the JRE installation path:

1. Right-click the My Computer icon on your desktop and select Properties.
2. Click the Advanced tab.
3. Click the Environment Variables button.
5. Enter the variable name as JAVA_HOME.
6. Enter the variable value as the installation path for the Java Development Kit. Don't use a trailing backslash, and don't wrap the value in quotes.
   - If your Java installation directory has a space in its path name, you should use the shortened path name (e.g. C:\Program-1\Java\jre7) in the environment variable instead.

   Note for Windows users on 64-bit systems

   Progra~1 = 'Program Files'
   Progra~2 = 'Program Files(x86)'

7. Click OK.
8. Click Apply Changes.
9. Close any command window which was open before you made these changes, and open a new command window. There is no way to reload environment variables from an active command prompt. If the changes do not take effect even after reopening the command window, restart Windows.

Now, in a new command prompt, try running '%JAVA_HOME%\bin\java -version'. You should see the same version of Java as you saw in 2. above.

Windows 7 ...

Stage 1. Locate the JRE Installation Directory

If you already know the installation path for the Java Runtime Environment, go to Stage 2 below. Otherwise, find the installation path by following these instructions:

1. If you didn't change the installation path for the Java Runtime Environment during installation, it will be in a directory under C:\Program Files\Java. Using Explorer, open the directory C:\Program Files\Java.
2. Inside that path will be one or more subdirectories such as C:\Program Files\Java\jre7.

Stage 2. Set the JAVA_HOME Variable

1. Go to Start, search for "sys env" and choose Edit the system environment variables.
2. Click Environment Variables, and then New under 'System variables'.
3. Enter "JAVA_HOME" as the Variable name, and the absolute path to where you installed Java as the Variable value. Don't use a trailing backslash, and don't wrap the value in quotes.

Now, in a new command prompt, try running '%JAVA_HOME%\bin\java -version'. You should see the same version of Java as you saw in 2. above.
4. Check your versions of Git and Perl

In a command prompt, run:

```
$ git --version
$ perl --version
```

The version of Git should be 1.7.6 or higher. The version of Perl should be 5.8.8 or higher.

If you don't see supported versions of Git and Perl, then get them...

Download the Full installer for official Git for Windows. Installing Git for Windows (msysGit) also installs a supported version of Perl.

Run the Git installer. Ensure that git.exe is available in the path:

- Option 2, "Run Git from the Windows Command Prompt", or Option 3, "Run Git and included Unix tools from the Windows Command Prompt", will both work with Stash.
- Do not select Option 1, "Use Git Bash only" -- this will not work with Stash.

5. Now it’s time to get Stash

Download Stash from the Atlassian download site. Looking for the Stash WAR file?

Extract the downloaded file to an install location. The path to the extracted directory is referred to as the <Stash installation directory> in these instructions.

Note that you should use the same user account to both extract Stash and to run Stash (in Step 7) to avoid possible permission issues at startup. Don’t use spaces in the path to the Stash installation directory.

6. Tell Stash where to store your data
The Stash home directory is where your Stash data is stored.

Create your Stash home directory, and then tell Stash where you created it by setting a STASH_HOME environment variable, as follows.

For Windows 7:

1. Go to Start, search for "sys env" and choose **Edit the system environment variables**.
2. Click **Environment Variables**, and then **New** under 'System variables'.
3. Enter "STASH_HOME" as the **Variable name**, and the absolute path to your Stash home directory as the **Variable value**. Don't use a trailing backslash.

There are a few things to know about setting up the Stash home directory on Windows that will make life easier:

- You **should not** locate your Stash home directory inside the `<Stash installation directory>` — they should be entirely separate locations. If you do put the home directory in the `<Stash installation directory>` it will be overwritten, and lost, when Stash gets upgraded. And, by the way, you can't use the same Stash home directory for multiple instances of Stash.
- Keep the path length to the Stash home directory as short as possible. See **Pull request merges can fail when Stash is hosted on Windows** for an explanation.
- Don't use spaces in the path to the Stash home directory.

7. **Start Stash!**

The user that runs Stash **should not** have admin privileges (see this **performance issue**), but must have read, write and execute access to the Stash home directory and the `<Stash installation directory>`.

In a command prompt, change directory to the `<Stash installation directory>` and run the following command:

```
bin\start-stash.bat
```

In your browser, go to `http://localhost:7990` and run through the Setup Wizard. In the Setup Wizard:

- Select **Internal** at the 'Database' step, if you are evaluating Stash. Stash will happily use its internal database, and you can easily migrate to external database later. See **Connecting Stash to an external database**.
- Set up JIRA integration now, or do this later if you wish. See **Configuring JIRA integration in the Setup Wizard**.

8. **Set up your mail server**

Configure your email server so users can receive a link from Stash that lets them generate their own passwords. See **Setting up your mail server**.

9. **Add users and repositories**

Now is the time to set up your users in Stash, and to tell Stash about any existing repositories you have. Please the following pages for the details:

- **Getting started with Git and Stash**
- **Importing code from an existing project**

**Additional steps for production environments**

For production environments we recommend that you configure the additional aspects below. These are not necessary when installing for evaluation purposes. Please see **Using Stash in the enterprise** for more information about best practice.

**Install and run Stash as a dedicated user**

- For production environments Stash should be run from a dedicated user account with restricted...
Use an external database

- For production environments Stash should use an external database, rather than the embedded

against unauthorised access. See Stash home directory.

Secure Stash with HTTPS

- For production environments access to Stash should be secured using HTTP over SSL, especially if your
data is sensitive and Stash is exposed to the internet. See Securing Stash with Tomcat using SSL.

Change the context path for Stash

- Where you are running Stash behind a proxy, or you have another Atlassian application, or any Java web
application, available at the same hostname and context path as Stash, then you should set a unique
context path for Stash. See Moving Stash to a different context path.

Stopping Stash (optional)

In a command prompt, change directory to the `<Stash installation directory>` and run:

```
bin\stop-stash.bat
```

Uninstalling Stash

To uninstall Stash, stop Stash as described above and then delete the `<Stash installation directory>`
and Stash home directory.

Running Stash as a Windows service

For long-term use on a Windows server, Stash should be configured to run as a Windows service. This has the
following advantages:

- Stash will be automatically restarted when the operating system restarts.
- Stash is less likely to be accidentally shut down, as can happen if the console window Stash
  was manually started in is closed.
- Stash logs are properly managed by the Windows service.

Setting up Stash as a Windows service

To run Stash as a Windows service:

1. Stop Stash.
2. Open a Command Prompt (as an Administrator – see the Before you start section above).
3. Change directory to the Stash installation directory and then into the bin subdirectory. If a directory in the path has spaces (e.g. C:\Program Files\..), use its eight-character equivalent (e.g. C:\Progra~1\..).
4. Run the following commands:

```bash
> service.bat install
> tomcat7 //US//STASH --Startup auto
```

This will create a service with the name "STASH" and a display name of "Atlassian Stash". If you would like to customize the name you can instead run:

```bash
> service.bat install MyName
> tomcat7 //US//MyName --Startup auto
```

This will create the service as "MyName" with a display name of "Atlassian Stash MyName".
5. Run the following command to increase the amount of memory that Stash can use (the default is 768 Mb):

```bash
> tomcat7 //US//service_name --JvmMx 1024
```

6. Verify that the Stash service comes back up after restarting the machine.

Here is an example:

Troubleshooting

- Problems may occur when trying to set up Stash to run as a Windows service with JRE 1.6. The problem is due to failure to locate MSVCR71.DLL, which can be found in %JAVA_HOME%/bin. There are two options to resolve this problem:
  - Add %JAVA_HOME%/bin to PATH, then restart the Stash server.
  - Copy MSVCR71.DLL to system path, C:\WINDOWS\SYSTEM32 or C:\WINNT\SYSTEM32.
- If your service fails to start with "code 4", make sure you ran service.bat install in a Command Prompt running as an Administrator.

Installing Stash on Linux and Mac

Hey! We're going to install Stash on a Linux box, or a Mac. There are a few steps, but we think you'll really like Stash once it's up and running.

If you are installing Stash for production or enterprise use, first check the additional steps at the bottom of this page and read Using Stash in the enterprise.

1. Check supported platforms

Better check the Supported platforms page first; it lists the application servers, databases, operating systems, web browsers and Java versions that we have tested Stash with and recommend.

Atlassian only officially supports Stash running on x86 hardware and 64-bit derivatives of x86 hardware.
The version of Java should be 1.7.x (Java 1.8 is not supported yet).

If you don't see Java 1.7.x then get Java...

Install Java

Download Java Server JRE from Oracle's website, and install it (note that Java 1.8 is not supported by Stash yet).

Now try running 'java -version' again to check the installation. The version of Java should be 1.7.x.

Check that the system can find Java

In a terminal, run this:

```bash
echo $JAVA_HOME
```

You should see a path like /System/Library/Frameworks/JavaVM.framework/Versions/CurrentJDK/Home/.

Set your JAVA_HOME if you don't see a path

### Linux

Do either of the following:

- If JAVA_HOME is not set, log in with 'root' level permissions and run:

  ```bash
echo JAVA_HOME="path/to/JAVA_HOME" >> /etc/environment
  ```

  where path/to/JAVA_HOME may be like: /System/Library/Frameworks/JavaVM.framework/Versions/CurrentJDK/Home/

- If JAVA_HOME needs to be changed, open the /etc/environment file in a text editor and modify the value for JAVA_HOME to:

  ```bash
  JAVA_HOME="path/to/JAVA_HOME"
  ```

  It should look like:

  ```bash
  JAVA_HOME=/System/Library/Frameworks/JavaVM.framework/Versions/CurrentJDK/Home/
  ```

### Mac

Open your ~/.profile file in a text editor and insert:

```bash
JAVA_HOME="path/to/JAVA_HOME"
export JAVA_HOME
```

where path/to/JAVA_HOME may be like: /System/Library/Frameworks/JavaVM.framework/Versions/CurrentJDK/Home/

Refresh your ~/.profile in the terminal and confirm that JAVA_HOME is set:

```bash
source ~/.profile
$JAVA_HOME/bin/java -version
```

You should see a version of Java that is 1.7.x, like this:

```bash
java version "1.7.0_1"
```

3. Check your versions of Git and Perl

In a terminal, run this:
git --version
perl --version

The version of Git should be **1.7.6** or higher. The version of Perl should be **5.8.8** or higher.

*If you don't see supported versions of Git and Perl...*

- Download and install the latest stable Git release from the [Git website](https://git-scm.com/download/win).
- Now try running `git --version` again. The version of Git should be **1.7.6** or higher.

Please note the following:

- See the [Git resources](https://git-scm.com/book) page for links to more Git download sites.
- At the time of writing, the default Git version on Ubuntu Linux is 1.7.5.x, which is too old for Stash: see [https://launchpad.net/~git-core/+archive/ppa](https://launchpad.net/~git-core/+archive/ppa).
- At the time of writing, on Mac OS X, the Git tar archive can fail on special characters when using SSH to secure connections between your computer and Stash. (The Git `archive` command allows you to download as a single file the files in a checkout of the Git repository.)
  We recommend that you use the zip format; you can set that using the following command:

  ```
  git archive --format zip
  ```

- Download and install the latest stable Perl release from [http://www.perl.org/get.html](http://www.perl.org/get.html), or use your favourite package manager.
- Now try running `perl --version` again. The version of Perl should be **5.8.8** or higher.

4. Now it's time to get Stash

Download Stash from the Atlassian download site. Looking for the Stash WAR file?

Extract the downloaded file to an install location. The path to the extracted directory is referred to as the `<Stash installation directory>` in these instructions. Note that you should use the same user account to both extract Stash and to run Stash (in Step 6) to avoid possible permission issues at startup.

5. Tell Stash where to store your data

The Stash home directory is where your Stash data is stored.

Create your Stash home directory (without spaces in the name), and then tell Stash where you created it by editing the `<Stash installation directory>/bin/setenv.sh` file — uncomment the `STASH_HOME` line and add the absolute path to your home directory. Here’s an example of what that could look like when you’re done:

```bash
# One way to set the STASH_HOME path is here via this variable. Simply uncomment it and set a valid path. #/stash/home. You can of course set it outside in the command terminal; that will also work.
STASH_HOME="/Users/spittet/stash-home"

# Occasionally Atlassian Support may recommend that you set some specific JVM arguments. You can use the # below to do that.
```

⚠️ You should not locate your Stash home directory inside the `<Stash installation directory>` — they should be entirely separate locations. If you do put the home directory in the `<Stash installation directory>` it will be overwritten, and lost, when Stash gets upgraded. And by the way, you'll need separate Stash home directories if you want to run multiple instances of Stash.
6. Start Stash!

In a terminal, change directory to `<Stash installation directory>` and run this:

```
bin/start-stash.sh
```

In your browser, go to `http://localhost:7990` and run through the Setup Wizard. In the Setup Wizard:

- Select **Internal** at the ‘Database’ step, if you are evaluating Stash. Stash will happily use its internal database, and you can easily migrate to external database later. See Connecting Stash to an external database.
- You can set up JIRA integration, but you can do this later if you wish. See Configuring JIRA integration in the Setup Wizard.

7. Set up your mail server

Configure your email server so users can receive a link from Stash that lets them generate their own passwords. See Setting up your mail server.

8. Add users and repositories

Now is the time to set up your users in Stash, and to tell Stash about any existing repositories you have. Please the following pages for the details:

- Getting started with Git and Stash
- Importing code from an existing project

Additional steps for production environments

For production or enterprise environments we recommend that you configure the additional aspects below. These are not necessary when installing for evaluation purposes. Please see Using Stash in the enterprise for more information about best practice.

Install and run Stash as a dedicated user

- For production environments Stash should be run from a dedicated user account with restricted privileges. See Running Stash with a dedicated user.

Use an external database

- For production environments Stash should use an external database, rather than the embedded database. See Connecting Stash to an external database.

Secure the Stash home directory

- For production environments the Stash home directory (created in step 7 above) should be secured against unauthorised access. See Stash home directory.

Secure Stash with HTTPS

- For production environments access to Stash should be secured using HTTP over SSL, especially if your data is sensitive and Stash is exposed to the internet. See Securing Stash with Tomcat using SSL.

Connect to your existing user directory

- See External user directories.

Change the context path for Stash

- Where you are running Stash behind a proxy, or you have another Atlassian application (or any Java web application) available at the same hostname and context path as Stash, then you should set a unique context path for Stash. See Moving Stash to a different context path.
Install Stash as a service

- See Running Stash as a Linux service

Stopping Stash (optional)

In a terminal, change directory to `<Stash installation directory>` and run this:

```
bin/stop-stash.sh
```

Uninstalling Stash

To uninstall Stash, stop Stash as described above and then delete the `<Stash installation directory>` and Stash home directory.

Running Stash as a Linux service

System administration tasks are not supported by Atlassian. These instructions are only provided as a guide and may not be up to date with the latest version of your operating system.

For production use on a Linux server, Stash should be configured to run as a Linux service, that is, as a daemon process. This has the following advantages:

- Stash can be automatically restarted when the operating system restarts.
- Stash can be automatically restarted if it stops for some reason.
- Stash is less likely to be accidentally shut down, as can happen if the terminal Stash was manually started in is closed.
- Logs from the Stash JVM can be properly managed by the service.

Related pages:

- Installing Stash on Linux and Mac

There are different approaches to running Stash as a service on Linux:

- Use the Java Service Wrapper which a Java Application to be run as a UNIX Daemon.
- Use an `init.d` script to start Stash at boot time - this doesn’t restart Stash if it stops for some reason.

Note that Stash assumes that the external database is available when it starts; these approaches do not support service dependencies, and the startup scripts will not wait for the external database to become available.

On this page:

- Using the Java Service Wrapper
- Using an `init.d` script

Using the Java Service Wrapper

Stash can be run as a service on Linux using the Java Service Wrapper. The Service Wrapper is known to work with Debian, Ubuntu, and Red Hat.

The Service Wrapper provides the following benefits:

- Allows Stash, which is a Java application, to be run as a service.
- No need for a user to be logged on to the system at all times, or for a command prompt to be open and running on the desktop to be able to run Stash.
- The ability to run Stash in the background as a service, for improved convenience, system performance and security.
- Stash is launched automatically on system startup and does not require that a user be logged in.
- Users are not able to stop, start, or otherwise tamper with Stash unless they are an administrator.
- Can provide advanced failover, error recovery, and analysis features to make sure that Stash has the maximum possible uptime.

The service wrapper supports the standard commands for SysV init scripts, so it should work if you just create a symlink to it from /etc/init.d.

**Using an init.d script**

The usual way on Linux to ensure that a process restarts at system restart is to use an init.d script. This approach does not restart Stash if it stops by itself.

1. **Stop Stash**.
2. Create a stash user, set the permissions to that user, create a home directory for Stash and create a symlink to make upgrades easier:

   ```
   $> export VERSION="2.8.1" # Set this to the version you want to install
   $> tar xz -C /opt -f atlassian-stash-$VERSION.tar.gz
   $> ln -s /opt/atlassian-stash-$VERSION /opt/atlassian-stash-latest
   
   # Create a home directory
   $> mkdir /opt/stash-home
   
   # ! Update permissions and ownership accordingly
   ```

3. Create the **startup script** in `/etc/init.d/stash` with the following contents (Ensure the script is executable by running `chmod 755 stash`) *Note: this is only an example, please adjust the script for your platform:*

   ```
   #!/bin/sh
   ### BEGIN INIT INFO
   # Provides:          stash
   # Required-Start:    $remote_fs $syslog
   # Required-Stop:     $remote_fs $syslog

   # Default-Stop:      0 1 6
   # Short-Description: Initscript for Atlassian Stash
   # Description:  Automatically start Atlassian Stash when the system starts up. Provide commands for manually starting and stopping Stash.

For RHEL (and derivates) use:

```bash
chkconfig --add stash --level 0356
```

Note: You may have to install the `redhat-1sb` package on RHEL (or derivatives) to provide the LSB functions used in the script.

You may also be interested in an alternative startup script optimised for usage in RHEL based systems: https://answers.atlassian.com/questions/218946/stash-system-v-init-script-for-rhel

### Configuring JIRA integration in the Setup Wizard

This page describes the ‘JIRA integration’ screen of the Stash setup wizard.

You can connect your application to a JIRA server, to manage your users via JIRA and share information with JIRA. When you are installing the application, the setup wizard gives you the opportunity to configure the JIRA connection automatically. This is a quick way of setting up your JIRA integration with the most common options.

You can also configure the JIRA connections via the application administration screens. In that case, you will need to set up connections individually. There are two parts to the integration process:

- A peer-to-peer link between JIRA and the application for sharing information and facilitating integration features. This link is set up via Application Links.
- A client-server link between the application and JIRA for delegating user and group management to your JIRA server.

**Requirements:** You need JIRA 4.3 or later.

On this page:

- Connecting to JIRA in the Setup Wizard
- Troubleshooting
- Notes

### Connecting to JIRA in the Setup Wizard

To configure JIRA integration while running the Stash setup wizard:

1. Configure the following setting in JIRA: **Allow remote API access**.
2. Click **Integrate with JIRA** and enter the following information when you get to the ‘Connect to JIRA’ step of the setup wizard:
### JIRA base URL
The web address of your JIRA server. Examples are:
- http://www.example.com:8080/jira/
- http://jira.example.com

### JIRA admin username
The credentials for a user with the 'JIRA System Administrators' global permission in JIRA.

### JIRA password

### Stash base URL
JIRA will use this URL to access your Stash server. The URL you give here will override the base URL specified in your Stash administration console, for the purposes of the JIRA connection.

We recommend that you make use of the automatic back-linking from JIRA to Stash.

3. Click **Connect**.
4. Finish the setup process.

The setup wizard successfully established the peer-to-peer link with JIRA, but could not persist the client-server link for user management in your `config.xml` file. This may be caused by a problem in your environment, such as a full disk.

Please investigate and fix the problem that prevented the application from saving the configuration file to disk. Then remove the partial configuration if it exists, try the 'Connect to JIRA' step again, and then continue with the setup. Detailed instructions are below.

The setup wizard displays the following error message:
- Error reloading Crowd authentication

The setup wizard has completed the integration of your application with JIRA, but is unable to start synchronizing the JIRA users with your application.

Restart your application. You should then be able to continue with the setup wizard. If this solution does not work, please contact Atlassian Support.

The setup wizard displays the following error message:
- An error occurred: java.lang.IllegalArgumentException: Could not create the application in JIRA/Crowd (code: 500). Please refer to the logs for details.

The setup wizard has not completed the integration of your application with JIRA. The links are only partially configured. The problem occurred because there is already a user management configuration in JIRA for this <application> URL.

Remove the partial configuration if it exists, try the 'Connect to JIRA' step again, and then continue with the setup. Detailed instructions are below.

No users can log in after you have set up the application with JIRA integration.

Possible causes:
- There are no users in the group that you specified on the 'Connect to JIRA' screen.
- For FishEye: There are no groups specified in the 'groups to synchronize' section of your administration console.
- For Stash: You may not have granted any JIRA groups or users permissions to log in to Stash.

Go to JIRA and add some usernames to the group.
- For FishEye: Go to the FishEye administration screens and specify at least one group to synchronize. The default is `jira-users`.
- For Stash: Grant the Stash User permission to the relevant JIRA groups on the Stash Global permissions page.

If this solution does not work, please contact Atlassian Support.

<tbody>
<tr>
<td>If the application’s setup wizard fails part-way through setting up the JIRA integration, you may need to remove the partial configuration from JIRA before continuing with your application setup. Please follow the steps below.</td>
</tr>
</tbody>
</table>

Remove the partial configuration if it exists, try the 'Connect to JIRA' step again, and then continue with the setup wizard:

1. Log in to JIRA as a user with the 'JIRA System Administrators' global permission.
2. Click the 'Administration' link on the JIRA top navigation bar.
3. Remove the application link from JIRA, if it exists:
   a. Click **Application Links** in the JIRA administration menu. The 'Configure Application Links' page will appear, showing the application links that have been set up.
   b. Look for a link to your application. It will have a base URL of the application linked to JIRA. For example:
      - If you want to remove a link between JIRA and FishEye, look for the one where the **Application URL** matches the base URL of your FishEye server.
      - If you want to remove a link between JIRA and Confluence, look for the one where the **Application URL** matches the base URL of your Confluence server.
      - If you want to remove a link between JIRA and Stash, look for the one where the **Application URL** matches the base URL of your Stash server.
4. Remove the user management configuration from JIRA, if it exists:
   a. Go to the JIRA administration screen for configuring the applications that have been set up to use JIRA for user management:
      • In JIRA 4.3: Click ‘Other Applications’ in the ‘Users, Groups & Roles’ section of the JIRA administration screen.
      • In JIRA 4.4: Select ‘Administration’ > ‘Users’ > ‘JIRA User Server’.
   b. Look for a link to your application. It will have a name matching this format:

   `<Type> - <HostName> - <Application ID>`

   For example:

   ```
   FishEye / Crucible - localhost - 92004b08-5657-3048-b5dc-f886e662ba15
   ```

   Or:

   ```
   Confluence - localhost - 92004b08-5657-3048-b5dc-f886e662ba15
   ```

   If you have multiple servers of the same type running on the same host, you will need to match the application ID of your application with the one shown in JIRA. To find the application ID:
   • Go to the following URL in your browser:

   `<baseUrl>/rest/applinks/1.0/manifest`

   Replace `<baseUrl>` with the base URL of your application.
   For example:

   ```
   http://localhost:8060/rest/applinks/1.0/manifest
   ```

   • The application links manifest will appear. Check the application ID in the `<id>` element.
   c. In JIRA, click ‘Delete’ next to the application that you want to remove.

5. Go back to the setup wizard and try the ‘Connect to JIRA’ step again.

Solution 2: Removing a Partial Configuration – The Longer Way

If solution 1 above does not work, you may need to remove the partial configuration and then add the full integration manually. Please follow these steps:

1. Skip the ‘Connect to JIRA’ step and continue with the setup wizard, to complete the initial configuration of the application.
2. Log in to JIRA as a user with the ‘JIRA System Administrators’ global permission.
3. Click the ‘Administration’ link on the JIRA top navigation bar.
4. Remove the application link from JIRA, if it exists:
   a. Click Application Links in the JIRA administration menu. The ‘Configure Application Links’ page will appear, showing the application links that have been set up.
   b. Look for a link to your application. It will have a base URL of the application linked to JIRA. For example:
      • If you want to remove a link between JIRA and FishEye, look for the one where the Application URL matches the base URL of your FishEye server.
      • If you want to remove a link between JIRA and Confluence, look for the one where the Application URL matches the base URL of your Confluence server.
   c. In JIRA, click ‘Delete’ next to the application that you want to remove.

Go back to the setup wizard and try the ‘Connect to JIRA’ step again.
application URL matches the base URL of your Confluence server.

- If you want to remove a link between JIRA and Stash, look for the one where the Application URL matches the base URL of your Stash server.

5. Remove the user management configuration from JIRA, if it exists:

   a. Go to the JIRA administration screen for configuring the applications that have been set up to use JIRA for user management:
      
      - In JIRA 4.3: Click 'Other Applications' in the 'Users, Groups & Roles' section of the JIRA administration screen.
      - In JIRA 4.4: Select 'Administration' > 'Users' > 'JIRA User Server'.

   b. Look for a link to your application. It will have a name matching this format:

   

   For example:

   

   FishEye / Crucible - localhost -
   92004b08-5657-3048-b5dc-f886e662ba15

   Or:

   

   Confluence - localhost -
   92004b08-5657-3048-b5dc-f886e662ba15

   If you have multiple servers of the same type running on the same host, you will need to match the application ID of your application with the one shown in JIRA. To find the application ID:

   a. Go to the following URL in your browser:

   

   http://localhost:8060/rest/applinks/1.0/manifest

   Replace <baseUrl> with the base URL of your application.

   For example:

   

   http://localhost:8060/rest/applinks/1.0/manifest

   - The application links manifest will appear. Check the application ID in the <id> element.

   c. In JIRA, click 'Delete' next to the application that you want to remove.

6. Add the application link in JIRA again, so that you now have a two-way trusted link between JIRA and your application:

   a. Click Add Application Link. Step 1 of the link wizard will appear.
   b. Enter the server URL of the application that you want to link to (the 'remote application').
   c. Click Next.
   d. Enter the following information:

   - Create a link back to this server – Check to add a two-way link between the two applications.
   - Username and Password – Enter the credentials for a username that has administrator access to the remote application.
     Note: These credentials are only used to authenticate you to the remote application, so that Application Links can make the changes required for the new link. The credentials are not saved.
   - Reciprocal Link URL – The URL you give here will override the base URL specified in your remote application's administration console, for the purposes of the application links connection. Application Links will use this URL to access the remote application.

   e. Click Next.
f. Enter the information required to configure authentication for your application link:
   - **The servers have the same set of users** – Check this box, because the users are the same in both applications.
   - **These servers fully trust each other** – Check this box, because you trust the code in both applications and are sure both applications will maintain the security of their private keys.
   *For more information about configuring authentication, see Configuring Authentication for an Application Link.*

g. Click **Create**.

7. Configure a new connection for user management in JIRA:
   a. Go to the JIRA administration screen for configuring the applications that have been set up to use JIRA for user management:
      - In JIRA 4.3: Click ‘Other Applications’ in the ‘Users, Groups & Roles’ section of the JIRA administration screen.
      - In JIRA 4.4: Select 'Administration' > 'Users' > 'JIRA User Server'.
   b. **Add** an application.
   c. Enter the **application name** and **password** that your application will use when accessing JIRA.
   d. Enter the **IP address** or addresses of your application. Valid values are:
      - A full IP address, e.g. 192.168.10.12.
      - A wildcard IP range, using CIDR notation, e.g. 192.168.10.1/16. For more information, see the introduction to CIDR notation on Wikipedia and RFC 4632.
   e. **Save** the new application.

8. Set up the JIRA user directory in the application.
   - **For Confluence**:
     a. Go to the **Confluence Administration Console**.
     b. Click ‘User Directories’ in the left-hand panel.
     c. **Add** a directory and select type ‘Atlassian JIRA’.
     d. Enter the following information:
        - **Name** – Enter the name of your JIRA server.
        - **Server URL** – Enter web address of your JIRA server. Examples:
          
          - http://www.example.com:8080/jira/
          - http://jira.example.com
        - **Application name** and **Application password** – Enter the values that you defined for Confluence in the settings on JIRA.
     e. Save the directory settings.
     f. Define the **directory order** by clicking the blue up- and down-arrows next to each directory on the 'User Directories' screen.
        *For details see Connecting to Crowd or JIRA for User Management.*
   - **For FishEye/Crucible**:
     a. Click **Authentication** (under ‘Security Settings’).
     b. Click **Setup JIRA/Crowd authentication**. Note, if LDAP authentication has already been set up, you will need to remove that before connecting to JIRA for user management.
     c. Make the following settings:

<table>
<thead>
<tr>
<th>Authenticate against</th>
<th>Select a JIRA instance</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Application name and password</strong></td>
<td>Enter the values that you defined for your application in the settings on JIRA.</td>
</tr>
</tbody>
</table>
### JIRA URL

<table>
<thead>
<tr>
<th>The web address of your JIRA server. Examples:</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="http://www.example.com:8080/jira/">http://www.example.com:8080/jira/</a></td>
</tr>
<tr>
<td><a href="http://jira.example.com">http://jira.example.com</a></td>
</tr>
</tbody>
</table>

### Auto-add

Select **Create a FishEye user on successful login** so that your JIRA users will be automatically added as a FishEye user when they first log in.

### Periodically synchronise users with JIRA

Select **Yes** to ensure that JIRA will synchronize all changes in the user information on a regular basis. Change the value for **Synchronise Period** if required.

### When Synchronisation Happens

Select an option depending on whether you want to allow changes to user attributes from within FishEye.

### Single Sign On

Select **Disabled**. SSO is not available when using JIRA for user management and if enabled will make the integration fail.

---

d. Click **Next** and select at least one user group to be synchronised from JIRA. If necessary, you could create a new group in JIRA, such as 'fisheye-users', and select this group here.
e. Click **Save**.

- For Stash:
  a. Go to the Stash administration area.
  b. Click **User Directories** in the left-hand panel.
  c. **Add** a directory and select type **Atlassian JIRA**.
  d. Enter the following information:
     - **Name** – Enter the name of your JIRA server.
     - **Server URL** – Enter web address of your JIRA server. Examples:
       - http://www.example.com:8080/jira/
       - http://jira.example.com
     - **Application name** and **Application password** – Enter the values that you defined for Stash in the settings on JIRA.
e. Save the directory settings.
f. Define the directory order by clicking the blue up- and down-arrows next to each directory on the ‘User Directories’ screen.
For details see Connecting Stash to JIRA for user management.

### Notes

When you connect to JIRA in the setup wizard, the setup procedure will configure OAuth authentication between Stash and JIRA. See Configuring OAuth Authentication for an Application Link for more information.

### Installing and upgrading Git

This page describes:

---

*On this page:*
Check your version of Git

You can check your current version of Git by running the `git --version` command in a terminal (Linux, Mac OS X) or command prompt (Windows). The Stash server requires one of these versions of Git: 1.7.6+, 1.8.0 – 1.8.4.2, 1.8.4.4+.

For example:

```
git --version
git version 1.7.7.3
```

See Supported platforms for more details about supported versions of Git.

If you don’t see a supported version of Git, you’ll need to either upgrade Git or perform a fresh install, as described below.

Installing or upgrading Git on Linux

Use your package manager to install Git. For example, on Ubuntu 13.10, use:

```
sudo apt-get install git
```

If you are using a different Linux distribution, you may need to use a different package repository to get the latest stable version of Git.

Now check the Git version – you should see the new version of Git.

If you still can’t see the Git version, you may need to add the Git install location to your path. Open your `~/.profile` file in a text editor and add this line, where `<path/to/git>` is the install location for Git:

```
export PATH=$PATH:<path/to/git>
```

You can use the `which git` command to find the install location for Git.

Installing or upgrading Git on Mac OS X

Download the latest stable Git release from the Git website. Click on the downloaded `.dmg` file, then double-click the `.pkg` icon to run the installer. This will install the new version of Git over the existing version:
Now check the Git version – you should see the new version of Git.

If you still can’t see the Git version, you may need to add the Git install location to your path. Open your ~/.profile file in a text editor and add this line, where <path/to/git> is the install location for Git:

```
export PATH=$PATH:<path/to/git>
```

You can use the `which git` command to find the install location for Git.

**Installing or upgrading Git on Windows**

Download the Full installer for official Git for Windows. Installing Git for Windows (msysGit) also installs a supported version of Perl.

⚠️ **msysGit is the only supported distribution** when running Stash on Windows. Cygwin Git is not supported and has known issues.

Run the Git installer, ensuring that you install into the same location as any existing Git installation. You can use `where git` to locate existing installations.

Ensure that `git.exe` is available in the path:

- Choose either Option 2, "Run Git from the Windows Command Prompt", or Option 3, "Run Git and included Unix tools from the Windows Command Prompt", will both work with Stash.
- Do not select Option 1, "Use Git Bash only" -- this will not work with Stash.
Now, check the Git version – you should see the new version of Git.

Restart Stash if necessary

If you’ve been installing or upgrading Git for the Stash server, rather than for your local machine, you’ll need to stop and restart Stash so that it will pick up the upgraded version of Git. In a terminal (Linux, Mac OS X) or command prompt (Windows), change directory to `<Stash installation directory>` and run:

**Linux and Mac OS X**

```
bin/stop-stash.sh
... wait for Stash to shut down ...
bin/start-stash.sh
```

**Windows**

```
bin\stop-stash.bat
... wait for Stash to shut down ...
bin\start-stash.bat
```

Getting started with Git and Stash

Atlassian Stash is the Git repository management solution for enterprise teams. It allows everyone in your organisation to easily collaborate on your Git repositories.

This page will guide you through the basics of Stash. By the end you should know how to:

- Create accounts for your collaborators, and organize these into groups with permissions.
- Create a project and set up permissions.
- Create repositories, and know the basic commands for interacting with them.
On this page:

- Assumptions
- Add users to Stash and grant permissions
- Create your first project and share it with collaborators
- Create a repository and get your code into Stash

Assumptions

This guide assumes that you don't have prior experience with Git. But we do assume that:

- You have Git version 1.7.6 or higher installed on your local computer.
- You are using a supported browser.
- You have Stash installed and running. See Installing Stash on Linux and Mac or Installing Stash on Windows.

Please read Git resources or check out our Git tutorials for tips on getting started with Git.

Add users to Stash and grant permissions

The first thing you can do in Stash is to add collaborators.

Go to the Stash administration area, by clicking the 'cog' menu in the header, and then click Users (under 'Accounts'):

Click Create User to go directly to the user creation form:
Once you've created a user, click **Change permissions** to set up their access permissions:

![Create User form]

There are 4 levels of user authentication:

- **System Administrator** — can access all the configuration settings of the Stash instance.
- **Administrator** — same as System Admins, but they can't modify file paths or the Stash server settings.
- **Project Creator** — can create, modify and delete projects.
- **Stash User** — active users who can access Stash.

See [Users and groups](#) for more information about authentication.
See External user directories if you have existing user identities you wish to use with Stash.

Create your first project and share it with collaborators

Creating your project

The next thing you do in Stash is to create a project. You'll add repositories to this project later.

Simply go to 'Projects' and click Create project. (Initially, you won't see as many projects as shown in this screenshot.)

Complete the form and submit it to create your new project:

See Creating projects for more information.

Opening up project access to others

If you are a project administrator, you can grant project permissions to other collaborators.

Click the Permissions tab for the project:
On that page you can add users and groups to a project you've already created.

There are 3 levels of project access:

- **Admin** — can create, edit and delete repositories and projects, and configure permissions for projects.
- **Write** — can push to and pull from all the repositories in the project.
- **Read** — can only browse code and comments in, and pull from, the repositories in the project.

See **Using project permissions** for more information.

### Create a repository and get your code into Stash

#### Create a repository

If you are a project administrator, you can create repositories in the project.

Once a repository is created, the project permissions are applied to the repository. That means all repositories created in a project share the same access and permission settings.

Click **Create repository** to open the repository creation form:

Once submitted you will be taken directly to your repository homepage. As there is no content in your repository yet, you'll see some instructions to help you push code to your repository.

See **Creating repositories** for more information.

#### A simple clone and push

This section describes how to clone the repository you just created and then push a commit back to it. You can see the clone URL to use at the top right of the screen. SSH access may be available.
In a terminal, run the following command (replace `<stashURL>` with the URL for your instance of Stash):

```
git clone <stashURL>/git/<projectname>/<reponame>.git
```

Use your Stash username and password.

The result in your terminal should be similar to what you can see in the screenshot below.

![Terminal screenshot](image)

You should now have a new empty directory tracked by Git, in the user space of your local machine. Let's add some content and push it back to Stash.

In your `<reponame>` directory, create a text file named `helloworld.txt` and write "Hello World" in it.

Now run the following command in your terminal

```
cd <reponame>
git add .
git commit -m "My first commit"
git push origin master
```

If everything went fine, when you refresh the Stash screen, you will see that the homepage of your repository has been replaced with a file browser showing you a link to `helloworld.txt`.

There you go, you’re ready to get coding with your collaborators.

For more information about getting your code into Stash, see Importing code from an existing project. Note that huge Git repositories (larger than a few GBs) are likely to impact the performance of the Git client – see this discussion.

Check out our Git tutorials and training for more information, and have a look at this list of basic Git commands that you will probably use often.

**Importing code from an existing project**

When creating a new repository, you can import code from an existing project into Stash. You can do this by first cloning the repository to your local system and then pushing to an empty Stash repository.

On this page:

- Import an existing, unversioned code project to an empty repository
- Import a Git project to an empty repository
- Mirror an existing Git repository

**Import an existing, unversioned code project to an empty repository**

If you have code on your local machine that is not under source control, you can put it under source control and import it into Stash. To do this:

1. Locally, change to the root directory of your existing source.
2. Initialise the project by running the following commands in the terminal:
3. Log into Stash and create a new repository.
4. Locate the clone URL at the top right (eg.: https://username@stash.atlassian.com/scm/PROJECT/repo.git).
5. Push your files to the repository by running the following commands in the terminal (change the URL accordingly):

   ```
   git init
   git add --all
   git commit -m "Initial Commit"
   ```

   ```
   git remote add origin
   https://username@stash.atlassian.com/scm/PROJECT/repo.git
   git push -u origin master
   ```

6. Done! Your repository is now available in Stash.

**Import a Git project to an empty repository**

You can import an existing repository into an empty project in Stash. When you do this, Stash maintains your commit history.

1. Check out the repository from your existing Git host. Use the `--mirror` parameter to include all branches and tags:

   ```
   git clone --mirror
   ```

2. Change the remote origin in your local repository to point to Stash (change the URL accordingly):

   ```
   git remote set-url origin
   https://username@stash.atlassian.com/scm/PROJECT/repo.git
   ```

3. Then push all branches to Stash:

   ```
   git push origin
   ```

**Mirror an existing Git repository**

You can mirror an existing repository into a repository hosted in Stash.

1. Check out the repository from your existing Git host. Use the `--mirror` parameter to include all branches and tags:

   ```
   git clone --mirror
   ```

2. Add Stash as another remote in your local repository:

   ```
   git remote add stash https://username@stash.atlassian.com/scm/PROJECT/repo.git
   ```

3. Then push all branches and tags to Stash
4. Using `git fetch origin`, and the `git push` commands listed in step 3, the repository in Stash can be updated with changes from the upstream repository.

**Basic Git commands**

Here is a list of some basic Git commands to get you going with Git.

For more detail, check out the Atlassian Git Tutorials for a visual introduction to Git commands and workflows, including examples.

<table>

</tr>
</thead>
<tbody>
<tr>
<td>git push origin &lt;branchname&gt;</td>
<td>Push branch to local</td>

<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>git push origin :&lt;branchname&gt;</td>
<td>Delete branch on remote</td>
</tr>
</tbody>
</table>

**Update from the remote repository**

Fetch and merge changes on the remote server to your working directory:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>git pull</td>
<td>Pull changes</td>
</tr>
</tbody>
</table>

To merge a different branch into your active branch:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>

</thead>
<tbody>
<tr>
<td>git merge &lt;branchname&gt;</td>
<td>Merge branch</td>
</tr>
</tbody>
</table>

View all the merge conflicts:

<table>
<thead>
<tr>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>git diff</td>
<td>View conflicts</td>
</tr>
</tbody>
</table>

View the conflicts against the base file:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>git diff --base &lt;filename&gt;</td>
<td>View base conflicts</td>
</tr>
</tbody>
</table>

Preview changes, before merging:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>git diff &lt;sourcebranch&gt; &lt;targetbranch&gt;</td>
<td>Preview changes</td>
</tr>
</tbody>
</table>

After you have manually resolved any conflicts, you mark the changed file:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>git add &lt;filename&gt;</td>
<td>Mark changed file</td>
</tr>
</tbody>
</table>

**Tags**

You can use tagging to mark a significant changeset, such as a release:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>git tag 1.0.0 &lt;commitID&gt;</td>
<td>Tag changeset</td>
</tr>
</tbody>
</table>

CommitID is the leading characters of the changeset ID, up to 10, but must be unique. Get the ID using:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>git log</td>
<td>Get commit ID</td>
</tr>
</tbody>
</table>

Push all tags to remote repository:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>git push --tags origin</td>
<td>Push tags to remote</td>
</tr>
</tbody>
</table>

**Undo local changes**

If you mess up, you can replace the changes in your working tree with the last content in head:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>git checkout -- &lt;filename&gt;</td>
<td>Undo local changes</td>
</tr>
</tbody>
</table>

Changes already added to the index, as well as new files, will be kept.

Instead, to drop all your local changes and commits, fetch the latest history from the server and point your local master branch at it, do this:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>git fetch origin</td>
<td>Fetch latest history</td>
</tr>
<tr>
<td>git reset --hard origin/master</td>
<td>Point master branch</td>
</tr>
</tbody>
</table>

**Search**

Search the working directory for `foo()`:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>git grep &quot;foo()&quot;</td>
<td>Search working directory</td>
</tr>
</tbody>
</table>

**Using Stash**

*Created in 2014 by Atlassian. Licensed under a Creative Commons Attribution 2.5 Australia License.*
Stash is the on-premises Git repository management solution for enterprise teams. It allows everyone in your organisation to easily collaborate on your Git repositories.

This section describes the essentials of using Stash.

If you are setting up Stash, see the Getting started section. If you want to configure Stash, see the Administering Stash section.

See Getting started with Git and Stash for an overview of how to work with Stash.

### Working with projects

Stash manages related repositories as projects. Find out how to set up projects and then give your teams access to those.

### Working with repositories

If you have existing projects that you want to manage in Stash, then you'll want to read Importing code from an existing project.

### Git resources

For those who are new to using Git:

- Using pull requests in Stash

### Creating projects

Projects allow you to group repositories and to manage permissions for them in an aggregated way.

To create a project, click on Create project:
Fill out the form. We recommend that you use a short project key. It will be used as an identifier for your project and will appear in the URLs.

Optionally, you can choose an avatar for the project. This is displayed throughout Stash and helps to identify your project.

Click **Create project** when you're done.

You'll want to add repositories to the project. See **Creating repositories** for details.
There are no repositories in this project yet.

Creating repositories
Repositories allow you to collaborate on code with your co-workers.

In order to create repositories you need to have Project Admin permission for the project to which you want to add a repository.

Once a repository is created, the project permissions are applied to the repository. That means all repositories created in a project share the same access and permission settings.

Click Create repository to open the repository creation form:

Once submitted you will be taken directly to your repository homepage. As there is no content in your repository yet, you'll see some instructions to help you push code to your repository:
You will find your clone URL in the upper right corner of the repository homepage. You can use this URL and share it with other people.

Let other people collaborate with you

In order to grant users access to this repository you have to set up permissions at the parent project level. More information is available on Creating projects.

Creating personal repositories

Stash allows you to create personal repositories, unrelated to other projects, that you can use for such purposes as storing private snippets of work, kick-starting your own project, or contributing a bug-fix for a project you are not a member of.

By default, personal repositories are not visible to other Stash users (unless they are a Stash system administrator). However, you can:

- use repository permissions to open up access to other Stash users and groups, for collaboration or review.
- allow public access (read-only) to your project, for anonymous users.

You can create personal repositories in 2 ways:

- Directly, from your profile.
- By forking another repository.

Your personal repositories are listed on the Repositories tab of your profile page. Every Stash user can see your profile page, but they can only see those repositories that you have given them permission to view.

Directly creating a personal repository

You can create a personal repository at any time from your Stash profile:

1. Choose View profile from your user menu in the header.
2. Click **Create repository**.
3. Set **repository permissions** on the new repository, if required.

**Forking another repository**

You can create a personal fork of any other repository in Stash for which you have permission:

1. Go to the repository that you wish to fork.
2. Click **Fork**.
3. Choose your own profile (this is selected by default) from the **Project** list:

4. Click **Fork repository**.
5. Set **repository permissions** on the new repository, if required.

**Using repository hooks**

Hooks in Stash provide a way to customise a team’s workflow and integrate with other systems. Stash currently supports two types of hooks, **pre** and **post-receive**.

On this page:

- Managing hooks
  - Pre-receive hooks
  - Post-receive hooks
- Getting hooks from the Atlassian Marketplace
- Creating your own hooks
- Learn more about Git hooks

Managing hooks
Administrators can see the hooks that are available in Stash by going to **Settings > Hooks** for a Stash repository. Once installed, hooks are available across all repositories in a Stash instance, but are enabled separately on each repository in a project.

![Hooks page in Stash settings](image)

Click the ‘pen’ icon beside the name of a hook to edit configuration details for the hook.

**HipChat Push Notification**

- **Room Name**: Stash Notifications
- **API Token**: 4561234598765433456789698765

Specify the HipChat room to receive notifications about pushes and merges.

You can get a list of available rooms from your HipChat client or through the [rooms page](https://hipchat.com). You must specify an **API token** (only a user token is required).

Stash currently ships with the following hooks:

- **Reject Force Push** – block all Git force pushes (`git push --force`).
- **HipChat Push Notifications** – send a message to a HipChat room when someone pushes to the repository.

**Pre-receive hooks**

The first hook to run when handling a push from a client is the pre-receive hook. It can reject pushes to the repository if certain conditions are not fulfilled. You can use this hook to prevent force pushes to the repository or check whether all commits contain a valid JIRA issue key.

**Post-receive hooks**

The post-receive hook runs after the commits have been processed and can be used to update other services or notify users. For example this post-receive hook could be used to send a message to a chat server or notify a continuous integration server such as [Atlassian Bamboo](https://atlassian.com) of the newly pushed changes.

**Getting hooks from the Atlassian Marketplace**
A number of hooks are available from the Atlassian Marketplace. You can find and install these from within Stash – simply use the Add hook button on the hooks settings page to view available hooks from the marketplace. See Managing add-ons for details.

Creating your own hooks

Developers can write receive hook plugins for Stash using a simple API that provides a simple way to create a configuration interface, and stores the hook's configuration settings on a per-repository basis.

For information about how to write your own hooks please see the Stash developer docs.

In particular, these pages will be helpful:

- Repository hooks
- Repository hook plugin module

Learn more about Git hooks

Hooks in Stash are executed on the server, but Git itself also provides support for client-side hooks meant for client operations such as committing and merging. Learn more about Git hooks in the Git documentation.

Note: Git post-receive hooks won't be triggered after a pull request merge. The mechanism that performs the pull request merge is actually based on a git fetch into the repository, which doesn't trigger Git post-receive hooks. If you would like to trigger functionality based on a pull request merge, you should write a post-receive repository hook.

Controlling access to code

Stash provides the following types of permissions to allow fully customisable control of access to code.

Note that you can also:

- allow public (anonymous) access to projects and repositories. See Allowing public access to code.
- use SSH keys to allow user accounts and other systems to connect securely to Stash repositories for Git operations. See Using SSH keys to secure Git operations.

Global permissions

- Control user and group access to Stash projects and to the Stash server configuration.
- For example, these can be used to control the number of user accounts that can access Stash for licensing purposes.
- See Global permissions.

Project permissions

- Apply the same access permissions to all repositories in a project.
- For example, these can be used to define the core development team for a project.
- See Using project permissions.

Repository permissions

- Extend access to a particular repository for other, non-core, users.
- For example, these can be used to allow external developers or consultants access to a repository for special tasks or responsibilities.
- See Using repository permissions.

Branch permissions

- Control commits to specific branches within a repository.
- For example, these can provide a way to enforce workflow roles such as the Release Manager, who needs to control merges to the release branch.
- See Using branch permissions.

Permissions matrix
The table below summarizes the cumulative effect of the permissions described above for anonymous and logged in users. In general, repository permissions override project permissions. A personal project can not be made public.

Using branch permissions

Branch permissions allow you to control who can commit to specific branches in a repository. Branch permissions provide another level of security within Stash (along with user authentication and project, repository and global permissions) that provides a way to control, or enforce, your own workflow or process.

Branch permissions:
- are based on users or groups.
- are actually restrictions, which are checked after project and repository level permissions.
- are used to limit branch access to specific people who must still have write access to the project or repository.
- prevent unauthorised users pushing to or deleting the branch.
- are based on explicit branch names, or you can use advanced branch permissions to match multiple branches (or tags) using pattern matching.

For example, if two developers Xavier and Yves have write access to repository R, but only Xavier has branch permissions on branch B, then Yves won't be able to push to B.

If a user does not have commit access to the branch, an error message will be shown on the Git command line when they try to push a change to the branch.

Note that if no branch permissions are defined then anyone with commit access to the repository can push to any branch.

On this page:
- Setting branch permissions
- Advanced branch permissions

Related pages:
- Using pull requests in Stash
- Controlling access to code
- Global permissions
You'll need either project admin, admin or sys-admin permissions to set branch permissions.

So, to set branch permissions:

1. Go to a repository in a project.
2. Choose Settings > Branch (under ‘Permissions’).
3. Click Add permission.
4. On the Branch tab, choose the branch for which you want to control access.
5. Add (or remove) users or groups that you want to have (or not have) commit access to the branch.
6. Click Create to finish.

You can always change the permissions for a branch later, if necessary.

### Advanced branch permissions

Advanced branch permissions specify a pattern that is matched against branches and tags being pushed to Stash; this allows you to restrict any pushes to branches that match the pattern.

Advanced branch permission also apply to attempts to create new branches; if a push to Stash attempts to create a new branch that matches a pattern, the user must be authorised for the operation to proceed.

To set advanced branch permissions, choose Settings > Branch, and click Add permission, as described above.

On the Advanced tab, enter a glob pattern to match the names of multiple branches for which you want to control access.
Branch permission patterns

Stash supports a powerful type of pattern syntax for matching branch names (similar to pattern matching in Apache Ant).

These expressions use the following wild cards:

<table>
<thead>
<tr>
<th>Wild Card</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>?</td>
<td>Matches one character (any character except path separators)</td>
</tr>
<tr>
<td>*</td>
<td>Matches zero or more characters (not including path separators)</td>
</tr>
<tr>
<td>**</td>
<td>Matches zero or more path segments.</td>
</tr>
</tbody>
</table>

Pattern used in branch permissions match against all refs pushed to Stash (i.e. branches and tags).

In git, branch and tag names can be nested in a namespace by using directory syntax within your branch names, e.g. `stable/1.1`. The '***' wild card selector enables you to match arbitrary directories.

- A pattern can contain any number of wild cards.
- If the pattern ends with `/` then `**` is automatically appended - e.g. `foo/` will match any branches or tags containing a `foo` path segment.
- Patterns only need to match a suffix of the fully qualified branch or tag name. Fully qualified branch names look like `refs/heads/master`, whilst fully qualified tags look like `refs/tags/1.1`.

Also see the Ant documentation.

Examples

<table>
<thead>
<tr>
<th>Pattern</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>Matches everything</td>
</tr>
</tbody>
</table>
| PROJECT-* | Matches and branch or tag named PROJECT-*, even in a name space.  
  e.g. `refs/heads/PROJECT-1234`, `refs/heads/stable/PROJECT-new` or
  `refs/tags/PROJECT-1.1` |
| ?.?        | Matches any branch or tag of 2 characters separated by a `.`.  
  e.g. `refs/heads/1.1`, `refs/heads/stable/2.X` or
  `refs/tags/3.1` |
Using repository permissions

Stash allows you to manage the permissions for just a single repository, or for a group of repositories together from the project.

Repository permissions allow you to extend access to a repository, for those who don't have project permissions. For example, you might use repository permissions to allow external developers or consultants access to a repository for special tasks or responsibilities.

Stash supports 3 levels of permissions for repositories:

- Admin
- Write
- Read

Depending on the permission level for the repository that has been granted to you, you can perform different actions in the repository:

Granting access to a repository

To modify it's permissions, go to the repository's settings and click on Repository (under 'Permissions'). Click in the Add Users or Add Groups field in the relevant section to search for, and bulk add, users or groups. Now choose a permission from the list and click Add.

Once added, you can use the checkboxes to edit specific permissions for an individual user or a particular group.

Granting access to all repositories within a project

If you have a large number of repositories in a project, project level permissions provide a convenient way to grant access to all repositories within that project. For example you can grant a group, say "Team A", Write access at the project level, which will automatically give them Write access to all existing repositories in the project, as well as any repositories that are subsequently created in the project.

To modify permissions for a project, click the Permissions tab when viewing the project. You can add, or
modify, permissions for individual users, and groups, in the same way as described above for a single repository.

Granting permission to create repositories

Only users with project administration permission can create new repositories.

Using project permissions

Stash allows you to manage the permissions for the repositories in a project in an aggregated way.

There are 3 levels of project permission that you can assign to a user or group for a project: Admin, Write and Read.

<table>
<thead>
<tr>
<th>Browse</th>
<th>Clone / Pull</th>
<th>Create, browse, comment on pull request</th>
<th>Merge pull request</th>

</tbody>
</table>

To modify permissions for a project, click the Permissions tab when viewing the project. Click in the Add Users or Add Groups field in the relevant section to search for, and bulk add, users or groups. Now choose a permission from the list and click Add.

Once added, you can use the checkboxes to edit specific permissions for individual users or particular groups.

Allowing public access to code

You can open up public access for anonymous (unauthenticated) users to projects and repositories in Stash.
This allows you to:

- Broadcast your repositories to a wider audience who generally don't have access to your source.
- Utilise unauthenticated cloning of repositories when setting up continuous integration servers to work with Stash.
- Link from other systems, for example JIRA or Confluence, to give users access to code without requiring authentication.
- Create open-source projects or repositories.

Public access allows anonymous users to browse the files, pull requests and commits for a specific repository or an entire project, and to clone repositories, without needing to log in, or have an account in Stash.

In Stash, you can:

- Configure a specific repository for public access.
- Configure a project to allow public access to all repositories in the project.
- Disable anonymous access by setting a global system property.

Making a repository publicly accessible

You can open up a specific repository for public (anonymous) access.

You need admin permission for the repository.

Go to the repository and choose Settings, then Repository (under 'Permissions'). Check Enable (under 'Public Access') to allow users without a Stash account to clone and browse the repository.

Making a project publicly accessible

You can open up a whole project (but not a private project) for public (anonymous) access.

You need admin permission for the repository, or its project.

Go to the project and choose Settings, then Permissions. Check Enable (under 'Public Access') to allow users without a Stash account to clone and browse any repository in the project.

Viewing public repositories

Stash displays a list of repositories for which anonymous access has been enabled.

Anonymous and logged-in users can choose Repositories > View all public repositories to see these.

Disabling public access globally

Stash provides a system property that allows you to turn off public access for the whole instance.

To do this, set the feature.public.access property to false in the stash.config.properties file in your Stash home directory.

Using SSH keys to secure Git operations

Stash provides a simple way for user accounts and other systems to connect securely to Stash repositories, using SSH keys, in order to perform Git operations. You can:

- add a personal key to a Stash user account to allow a developer to easily authenticate when performing read operations from his or her local machine. A Stash user can add any number of keys
to their account. Read more at SSH user keys for personal use.

- add an access key to a Stash project or repository to allow other systems, such as build servers like Atlassian’s Bamboo, to authenticate for either read-only (pull, clone) or read-write (push, merge) operations, without the need to store user credentials. Read more at SSH access keys for system use.

**Related pages:**

Before you can use SSH keys to secure a connection with Stash the following must have already been done:

- your Stash administrator must have already enabled SSH access in Stash.
- you need an SSH key! See Creating SSH keys. Alternatively, you can use an existing key, if it isn't already being used as a repository or project access key in Stash.

Note that:

- You can use the same SSH system access key for multiple repositories or projects.
- A Stash user can add any number of keys to their account.
- Keys used for personal user accounts can't be re-used as a project or repository access key, and keys used as a project or repository access key can't be re-used for user accounts.
- Stash supports DSA and RSA2 key types – RSA1 is not supported.

**Creating SSH keys**

This page describes how to create SSH keys.

SSH keys can be used to establish a secure connection with Stash for:

- when you are performing Git operations from your local machine
- when another system or process needs access to repositories in Stash (for example your build server)

The SSH key needs to be added to Stash, and your Stash administrator must have enabled SSH access to Git repositories, before you can make use of the key.

Supported key types are DSA and RSA2 – RSA1 is not supported.

**On this page:**

**Related pages:**
- Using SSH keys to secure Git operations

Creating an SSH key on Windows

1. **Check for existing SSH keys**

You should check for existing SSH keys on your local computer. You can use an existing SSH key with Stash if you want, in which case you can go straight to Using SSH keys to secure Git operations.

Open a command prompt, and run:

```
cd %userprofile%/.ssh
```

- If you see "No such file or directory", then there aren't any existing keys: **go to step 3**.
- Check to see if you have a key already:
If there are existing keys, you may want to use them: go to Using SSH keys to secure Git operations.

2. Back up old SSH keys

If you have existing SSH keys, but you don't want to use them when connecting to Stash, you should back those up.

In a command prompt on your local computer, run:

```
mkdir key_backup
copy id_rsa* key_backup
```

3. Generate a new SSH key

If you don't have an existing SSH key that you wish to use, generate one as follows:

1. Log in to your local computer as an administrator.
2. In a command prompt, run:

```
ssh-keygen -t rsa -C "your_email@example.com"
```

Associating the key with your email address helps you to identify the key later on.

Note that the `ssh-keygen` command is only available if you have already installed Git (with Git Bash). You'll see a response similar to this:

```
C:\Users\ASUS>ssh-keygen
Generating public/private rsa key pair.
Enter file in which to save the key (/c/Users/ASUS/.ssh/id_rsa):
Created directory '/c/Users/ASUS/.ssh'.
Enter passphrase (empty for no passphrase):
Enter same passphrase again:
Your identification has been saved in /c/Users/ASUS/.ssh/id_rsa.
Your public key has been saved in /c/Users/ASUS/.ssh/id_rsa.pub.
The key fingerprint is:
e6:99:3c:3c:e2:fb:9c:04:3f:df:4d:b2:80:11:a5:1e ASUS@ASUS-PC
C:\Users\ASUS>
```

5. You're done! Now add the new key to Stash.

Creating an SSH key on Linux & Mac OS X

1. Check for existing SSH keys

You should check for existing SSH keys on your local computer. You can use an existing SSH key with Stash if you want, in which case you can go straight to Using SSH keys to secure Git operations.

Open a terminal and run the following:
1. cd ~/.ssh

- If you see "No such file or directory, then there aren't any existing keys: go to step 3.
- Check to see if you have a key already:

        ls id_*

- If there are existing keys, you may want to use them; go to Using SSH keys to secure Git operations.

2. Back up old SSH keys

If you have existing SSH keys, but you don't want to use them when connecting to Stash, you should back those up.

Do this in a terminal on your local computer, by running:

        mkdir key_backup
        cp id_rsa* key_backup

3. Generate a new key

If you don't have an existing SSH key that you wish to use, generate one as follows:

   1. Open a terminal on your local computer and enter the following:

        ssh-keygen -t rsa -C "your_email@example.com"

Associating the key with your email address helps you to identify the key later on.

You'll see a response similar to this:

        pwatsons-Mac-Pro: ~ pwatson$ ssh-keygen
        Generating public/private rsa key pair.
        Enter file in which to save the key (/Users/pwatson/.ssh/id_rsa):
        Enter passphrase (empty for no passphrase):

   2. Just press <Enter> to accept the default location and file name. If the .ssh directory doesn't exist, the system creates one for you.
   3. Enter, and re-enter, a passphrase when prompted.
      The whole interaction will look similar to this:
4. You’re done! Now add the new key to Stash.

**SSH user keys for personal use**

You can use SSH keys to establish a secure connection between your computer and Stash for when you are performing read-only (pull, clone) Git operations from your local machine. Personal keys are attached to your Stash account – they are bound by that account’s permissions and use the account’s identity for any operations.

Before you can use SSH keys to secure a connection with Stash the following must have already been done:

- your Stash administrator must have already enabled SSH access in Stash.
- you need an SSH key! See Creating SSH keys. Alternatively, you can use an existing key, if it isn’t already being used as a repository or project access key.
- you need to have added your personal SSH key to your Stash account – see the following section.

Once you have an SSH key associated with your Stash account, using it is easy! See Use SSH keys to connect to Stash repositories below.

Note that:

- Stash supports DSA and RSA2 key types – RSA1 is not supported.
- A Stash user can add any number of keys to their account.
- You can use the same SSH access key for multiple repositories or projects.
- Keys used for personal user accounts can’t be re-used as a project or repository access key, and keys used as a project or repository access key can’t be re-used for user accounts.

Add an SSH key to your Stash account

1. On Windows, in your command prompt, change directory to your .ssh directory, and copy the public key file to your clipboard by running:

```
pwatsone-Mac-Pro:~ pwatson$ ssh-keygen
Generating public/private rsa ssh key pair.
Enter file in which to save the key (/Users/pwatson/.ssh/id_rsa):
Enter passphrase (empty for no passphrase):
Enter same passphrase again:
Your identification has been saved in /Users/pwatson/.ssh/id_rsa.
Your public key has been saved in /Users/pwatson/.ssh/id_rsa.pub.
The key fingerprint is:
The key’s randomart image is:

```

1. cd %userprofile%/.ssh
c  l p i < id_rsa.pub

On Mac OS X or Linux simply run the following in a terminal:

Mac OS X

pbcopy < ~/.ssh/id_rsa.pub

Note that on Linux, you may need to download and install xclip, then use that, as shown in this code snippet:

Linux

sudo apt-get install xclip
xclip -sel clip < ~/.ssh/id_rsa.pub

2. In Stash, go to your account:

3. Click on SSH keys and then Add key.
4. Paste the key into the text box:
5. Click **Add key**. You're done!

**Use SSH keys to connect to Stash repositories**

SSH access needs to have been set up, as described above. Once this is done, you can use SSH keys as follows:

1. Go to **Projects**, click a project, and choose a repository from the list.
2. Click **Clone** at the top right to see the clone URLs for the repository.
3. Choose the clone URL you want to use. SSH is available if you have already added an SSH key to your account. If you haven't done that yet, see Add an SSH key to your Stash account, above.

**SSH access keys for system use**

Stash administrators can set up SSH access keys to secure the Git operations that other systems perform on the repositories managed in Stash. Using access keys avoids the need to store user credentials on another system, and means that the other system doesn't have to use a specific user account in Stash. For example, access keys can be used to allow your build and deploy server to authenticate with Stash to check out and test source code.

- **Project admins** can add and manage SSH access keys for a project.
  The keys apply to every repository in the project.
- **Repository admins** can add and manage SSH access keys for a particular repository.
• The access key can allow either read-only or read-write Git operations.

Note that Stash supports DSA and RSA2 key types – RSA1 is not supported.

Before you can use SSH keys to secure a connection with Stash the following must have already been done:

• Your Stash administrator must have already enabled SSH access, on Stash.
• You must have already created an SSL key. See Creating SSH keys. Alternatively, you can use an existing key, if it isn’t already being used for a personal account in Stash.

Using SSH keys to allow access to Stash repositories

To get the SSH key to work with your build, or other, system, you need to:

• Add the private key to that system. For Bamboo, see this page: Sharing repository credentials.
• Add the public key to Stash as described here:

Add an SSH access key to either a Stash project or repository

You simply copy the public key, from the system for which you want to allow access, and paste it into Stash.

1. Copy the public key. One approach is to display the key on-screen using cat, and copy it from there:

   ```
   cat < ~/.ssh/id_rsa.pub
   ```

2. Now, in Stash, go to the Settings tab for the project or repository.
3. Click Access keys and then Add key.
4. Choose the Read permission, for git pull or git clone operations for example, where you want to be sure that the system will not be able to write back to the Stash repository.
Choose the Read / Write permission, for git push or git merge operations for example, where you may want your build system to merge successful feature branch builds to the default branch in the Stash repository, or so that deployments can be tagged.
Note that if you attempt to add a key already present on a project or repository but with a different permission to what it currently has, the permission will simply be updated.

5. Paste the key into the text box and click **Add key**.

#### Stash license implications

- System access keys do not require an additional Stash user license.

#### Reusing access keys

- You can use the same SSH access key for multiple repositories or projects.
- Keys used for personal user accounts can't be re-used as a project or repository system access key, and keys used as a project or repository access key can't be re-used for user accounts.

#### Deleting an access key

You can delete an access key by going to **Settings > Access keys** for the repository, and clicking the cross for the key (the cross only appears when you move the mouse pointer there):

### Access keys

<table>
<thead>
<tr>
<th>Label</th>
<th>Key</th>
<th>Permission</th>
</tr>
</thead>
<tbody>
<tr>
<td>csmajda@csm</td>
<td>ssh-rsa AAAAB3NzaC1yc2EAAAADAAAQABAAAABQAQC2ABpxSHgfjx0...</td>
<td>Read</td>
</tr>
<tr>
<td>csmajda@csl</td>
<td>ssh-rsa AAAAB3NzaC1yc2EAAAADAAAQABAAAABQAQC2ABpxSHgfjx0...</td>
<td>Read</td>
</tr>
</tbody>
</table>

If the key is used for multiple projects or repositories, you can select the other places that you want the key to be deleted from:
Note that the dialog only displays the projects and repositories that you have permission to see. Be aware that the key may also be used in other places that are not listed in the dialog. To be 100% sure that all uses of the key are deleted, this operation must be performed by someone with the administrator or sysadmin global permission.

**Workflow strategies in Stash**

Various Git workflows are supported by Stash:

- Centralized Workflow
- Feature Branch Workflow
- Gitflow Workflow
- Forking Workflow

For information about setting up Git workflows in Stash see Using branches in Stash and Using forks in Stash.

**Centralized Workflow**

Like Subversion, the Centralized Workflow uses a central repository to serve as the single point-of-entry for all changes to the project. Instead of trunk, the default development branch is called master and all changes are committed into this branch. This workflow doesn’t require any other branches besides master.

*Read more about the Centralized Workflow...*

**Feature Branch Workflow**

The core idea behind the Feature Branch Workflow is that all feature development should take place in a dedicated branch instead of the master branch. This encapsulation makes it easy for multiple developers to work on a particular feature without disturbing the main codebase. It also means the master branch will never contain broken code, which is a huge advantage for continuous integration environments.

*Read more about the Feature Branch Workflow...*

**Gitflow Workflow**

The Gitflow Workflow defines a strict branching model designed around the project release. While somewhat more complicated than the Feature Branch Workflow, this provides a robust framework for managing larger projects.

*Read more about the Git Workflow...*
**Forking Workflow**

The Forking Workflow is fundamentally different than the other workflows discussed in this tutorial. Instead of using a single server-side repository to act as the “central” codebase, it gives every developer a server-side repository. This means that each contributor has not one, but two Git repositories: a private local one and a public server-side one.

**Using branches in Stash**

Stash makes it easy for each member of your team to use a branching workflow for your Git development process. Your workflow can be mapped to branches in the Stash ‘branching model’, allowing Stash to:

- guide your developers into making consistent naming decisions when creating branches.
- identify the type of each branch and apply actions like automatic merging accordingly.

On this page:

- Configuring the branching model
- Creating branches
- Automating the branch workflow
- Managing all your branches

See also Using branch permissions for information about restricting access to branches in Stash.

**Configuring the branching model**

Stash uses a ‘branching model’ to define the branch workflow for each repository. As a project administrator, configuring the model lets you:

- enable the branch types that will be available in your workflow.
- specify the naming convention to be used for each branch type.

The naming convention simply adds prefixes to branch names, so that branches of the same type get the same prefix.

To configure the branching model for a repository, go to Settings > Branching model for the repository and click Enable branching model. Note that for new repositories, the branching model is enabled by default, and uses the default branch prefixes.

Stash makes a number of branch types available, as described below. Use the checkboxes to enable just those branch types that map to your workflow. Note that several branch types have default branch naming prefixes (for example the default prefix for the ‘feature’ branch type is feature/), as shown:

**Development**

This is generally the integration branch for feature work and is often the default branch (e.g. master) or a named branch such as develop. In a workflow using pull requests, this is usually the branch where new feature branches are targeted. In other cases, developers might commit directly to this branch.

**Feature**

Feature branches are used for specific feature work or improvements. They generally branch from, and merge back into, the development branch, by means of pull requests. See Feature branch workflow.

**Production**

*Feature branch workflow*
The production branch is used while deploying a release. It branches from, and merges back into, the development branch. In a Gitflow-based workflow it is used to prepare for a new production release.

## Release

Release branches are used for release task and long-term maintenance of software versions. Typically, they branch from, and fixes are merged back into, the development branch. Merging into an older release branch allows for automatic merging to newer release branches as well as the development branch.

## Bugfix

Bugfix branches are typically used to fix release branches.

## Hotfix

Hotfix branches are used to quickly fix the production branch without interrupting changes in the development branch. In a Gitflow-based workflow, changes are usually merged into the production and development branches.

### Note that:

- Prefixes can't be empty.
- Prefixes can't be longer than 30 characters.
- Prefixes can't overlap; for example PROD and PRODUCT would be overlapping prefixes.
- For Stash instances using Microsoft SQL Server, prefixes can't use non-ASCII characters. See [STASH-3884](https://jira.atlassian.com/browse/STASH-3884) - Non-ASCII values used as branch model prefixes/branch names don't work in MSSQL.

## Creating branches

You can create a new branch when in JIRA (version 6.1 and above) or in Stash. Either way, you can override the settings that Stash suggests for the repository, branch type, branching point and branch name.

### From a JIRA issue

JIRA must be connected with Stash by an application link for this functionality to be available.

When viewing an issue in JIRA of JIRA Agile, click Create Branch (under 'Development' – you'll need the 'View Development Tools' project permission in JIRA to see this):

Choose the SCM, if more than one is available, where you want to create the branch:
Stash suggests the **Branch type** and **Branch name** based on the JIRA issue type and summary. Change the **settings** suggested by Stash, if necessary:

**Create branch for STASHDEV-2493**

- **Repository**: Paul Watson / stash
- **Branch type**: Feature
- **Branch from**: master
- **Branch name**: feature/STASHDEV-2493-enhance-the-data-

Stash suggests the **Branch type** and **Branch name** based on the JIRA issue type and summary. Notice that Stash displays the current **build status** beside the source branch picker. Change the **settings** suggested by Stash if necessary:

**From in Stash**

In Stash, choose **Create branch** from the **Actions** menu when viewing the **Files**, **Commits** or **Branches** tabs, or when viewing a particular branch.

Stash suggests the **Branch type** and **Branch name** based on the JIRA issue type and summary. Notice that Stash displays the current **build status** beside the source branch picker. Change the **settings** suggested by Stash if necessary:
Creating the branch

You can specify:

- the Repository
- the **Branch type**, if a branching model has been previously configured – choose Custom if you need an ad hoc branch type
- the branch point
- the **Branch name** – the prefix is based on the branch type you selected, and as defined by the branching model. Note that the branch name should follow your team's convention for this.

Note that Stash suggests a Branch type based on the JIRA issue type, when a branching model is configured. The mapping is:

<table>
<thead>
<tr>
<th>JIRA issue type</th>
<th>Stash branch type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bug</td>
<td>Bugfix</td>
</tr>
<tr>
<td>Story</td>
<td>Feature</td>
</tr>
<tr>
<td>New Feature</td>
<td>Feature</td>
</tr>
</tbody>
</table>

Once the new branch is created, Stash takes you to the file listing for that. You can now pull to your local repository and switch to the new branch.

Automating the branch workflow

Stash can automate some merges in the branch workflow, based on the branching model for the repository. This allows merges to be cascaded to newer branches of the same parent, subject to a few conditions, so reducing the need for manual maintenance of branches.

As a project administrator you can turn on automatic merging for a particular repository. Go to **Settings > Branching model** for the repository, and select **Enable automatic merging** (under 'Automatic merge').

If Stash cannot perform an automatic merge, perhaps because branch permissions prevent it, Stash creates a new pull request for that merge, and the automatic merge operation stops. This allows you to resolve the conflict locally before approving the new pull request, which may involve further cascading merges.
See Automatic branch merging for more information about the conditions for automatic merging, and how Stash determines the ordering of branches.

Managing all your branches

The branch listing page makes it easy to keep track of all the branches in your repository.

Searching for branches

You can easily find branches by using the search at the top of the table. Furthermore, if you’re using the Stash branch model, you can filter by branch type simply by searching for the prefix – for example, search for “feature/” to see all your feature branches.

You can find the feature and bugfix branches that haven’t yet been merged into a particular release (for example, "release/2.10") by changing the ‘base branch’ – just use the branch selector (arrowed in the screenshot below) to change the base branch, and refer to the Behind/Ahead and Pull requests columns.

Reading the table

Behind/Ahead

The Behind/Ahead column shows by how many commits a branch has diverged from the 'base branch' (for example, master). Use the branch selector (arrowed in the screenshot below) to change the base branch.

Pull requests

The Pull requests column shows the most relevant status from the pull requests against each branch – click an icon to see details. The status is:

- OPEN if there is at least one open pull request.
- MERGED if there are no open pull requests, and at least one pull request has been merged.
- DECLINED if there are no open or merged pull requests, and at least one pull request has been declined.

Builds

If you have an integrated build server, the Builds column shows the status of the latest build results published to Stash. The overall status is ‘passed’ if all the different builds (for example, unit tests, functional tests, deploy to staging) succeeded and ‘failed’ if at least one run failed for any of those. Click an icon to see details of the builds.

Actions

The Actions menus include tasks for working with branches:

- Check out in SourceTree
- Create a pull request
- Edit permissions
- Delete branch

Navigation

Choose Keyboard shortcuts from the Stash Help menu to see shortcuts to help you navigate quickly around the branch listing.

Checking on your branches

The branch listing allows you to:

- See how many commits behind or ahead your branch is compared to a chosen 'base branch'.
- See the latest status for pull requests originating from branches.
- See the build status of branches at a glance.
- The Pull requests status helps you to track the review and merge work that still needs to be done and can help with branch cleanup. For example, in combination with the Behind/Ahead information, you can decide whether to remove a feature branch that has already been merged.
• The **Behind/Ahead** column can help you to identify work in progress as well as stale branches.

### Automatic branch merging

Stash can automatically merge changes to newer release branches, thus reducing the need for manual maintenance of branches. To be able to do this, Stash has to be able to determine the *ordering of branches*, and relies on semantic versioning of branch names – for example Stash will order these branch names like this: `1.0.0 < 2.0.0 < 2.1.0 < 2.1.1`.

Note that:

- Automatic branch merging is subject to a few **conditions**.
- Automatic merging is off by default for new and existing repositories.
- You must explicitly enable automatic merging for each repository.
- The commit message will indicate that the merge was automatic.
- Stash records full audit log entries for automatic merges.

As a project administrator, turn on automatic merging by going to **Settings > Branching model** for a repository, and selecting **Enable automatic merging** (under 'Automatic merge').

On this page:

- **Conditions for automatic merging**
  - What happens if the automatic merge fails?
- **Branch ordering algorithm**
- **Ordering examples**

### Conditions for automatic merging

The following conditions must be satisfied for Stash to be able to automatically cascade changes:

- The Stash **branching model** must be configured for the repository.
- The 'release' branch type must be enabled for the repository.
- The merge must go via a pull request.
- The pull request must be made to a branch that is of the 'release' type.
- The target branch of the pull request must have branches that are newer than it.

### What happens if the automatic merge fails?

The automatic merge can fail for reasons such as:

- Branch permissions prevent cascading changes to a particular branch.
- Stash detects a conflict that prevents the merge.
- There is already an open pull request with the same source and target that the automatic merge would close.

For the first two cases, Stash creates a new pull request for the failed merge, and the automatic merge operation stops. This allows you to resolve the conflict locally before approving the new merge, which may start a new series of cascading merges. Note that pull request that gets automatically opened when a merge fails won't trigger the continuation of the initial merge chain if resolved locally (which is the approach that we recommend).

### Branch ordering algorithm

Stash is able to automatically merge changes to newer release branches, as long as Stash can determine the ordering of those branches. Ordering is based on semantic versioning in the naming pattern for branches.

Stash uses the following ordering algorithm to determine the branches in the merge chain:

- Branches are selected and ordered on the basis of the name of the branch that started the cascade (i.e. the target of the pull request for the merge).
- Branch names are split into tokens using any of these characters: underscore '', hyphen '', plus '+' or period '.'.
- Only branches matching the name of the pull request target are added into the merge path. Matching means that every token before the first numeric token must be equal to the corresponding tokens of the target branch's name.
- Branches are ordered by number, if a given token is numeric. When comparing a numeric token with an ASCII token, the numeric is ranked higher (i.e. is considered as being a newer version).
- If both tokens are numeric, a simple ASCII comparison is used.
- In the unlikely case of the above algorithm resulting in equality of 2 branch names, a simple string comparison is performed on the whole branch name.
- There is a limit of 30 merges.

### Ordering examples

The table below provides examples of branch naming patterns that Stash is able, and not able, to order correctly:

<table>
<thead>
<tr>
<th>GOOD</th>
<th>BAD</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>• release/1.0</td>
<td>• release/1.0</td>
<td>Stash tokenises on the '.' and the '+' of '1.0' and is able to order these branch names correctly.</td>
</tr>
<tr>
<td>• release/1.1-rc1</td>
<td>• release/stash_1.1</td>
<td>Stash tokenises on the '.' and the '_' but cannot recognise that 'stash_1.1' should follow '1.0'.</td>
</tr>
<tr>
<td>• release/1.1</td>
<td>• release/stash_1.2</td>
<td>Stash tokenises on the '.' and the '_' and orders the numeric parts of these branch names correctly.</td>
</tr>
<tr>
<td>• release/1.2</td>
<td>• release/stash_2.0</td>
<td></td>
</tr>
</tbody>
</table>

### Using forks in Stash
Forks provide an alternative workflow to using branches, for where particular developers have restricted (read-only) access to a repository. See Workflow strategies in Stash for more information.

You can fork a repository into any other project in Stash for which you have admin access. You can also create personal forks and give other developers access to that using repository permissions.

Creating a fork

You can create a fork for any repository that you can see in Stash (that is, for which you have 'read' permission).

Simply click Fork, near the top right of the screen, when viewing a repository. You can choose the location for the newly forked repository. Note that when a repository is forked into another project it will get that project's permissions, which may be less restrictive.
When creating the fork you can enable fork syncing to have Stash automatically keep your fork up-to-date with changes in the upstream repository.

Issuing a pull request for a fork

Pull requests for forks in Stash work just the way you'd expect. See Using pull requests in Stash.

When creating the pull request, you can choose the fork and the branch that contains the source to be pulled, as well as the destination fork and branch.

Merging a fork

Once a pull request has been approved by reviewers, it can be merged as usual. See Using pull requests in Stash.

Synchronizing with upstream

Once you fork a repository, your fork can be kept up-to-date with changes in the upstream repo either automatically by Stash or you can synchronize manually. You will still need to keep your remote working repository synced with your fork in Stash yourself. See Keeping forks synchronized for more details.

Disabling forking

Forking of repositories is available by default. However, you can turn off forking, on a per-repository basis, if this helps you to control your development process. You can do this on the Repository details tab of the repository settings.

Note that disabling forking on the parent repo doesn't delete any existing forks, and doesn't prevent those existing forks from being forked. Pull requests will still work from the existing forks. Furthermore, commits in the parent are viewable via the fork if the SHA1 hash is known to the user.

Pre-receive hooks and forks

Pre-receive hooks aren’t copied with the fork and so are not run when code is merged in a pull-request. This means that custom hooks are unable to prevent certain changes from being merged by pull requests from forks. Instead, the hook would have to also implement a merge-check (see https://developer.atlassian.com/stash/docs/latest/how-tos/repository-hooks.html).

Keeping forks synchronized

Fork syncing helps you to keep your fork in Stash up-to-date with changes in the upstream repository. Stash can do this automatically for all branches and tags you haven't modified in the fork.

If you have modified branches or tags in the fork, Stash will offer syncing strategies. Stash will never update your branch or tag in your fork if this means that your changes would be lost.

Note that syncing is about pulling recent upstream changes into your fork, whereas pull requests are about pushing your changes back to the upstream repository.
Enabling automatic fork syncing

You can enable automatic fork syncing when you first fork the repository:

You can also enable fork syncing at any later time by going to Settings > Fork syncing for the forked repository. Syncing is disabled by default.

What gets synced?

When performing automatic synchronization, Stash updates the fork as follows:

- for branches: Stash makes any fast-forward change, where there is no need to merge work and there is no risk of losing changes.
- for tags: Stash makes updates only if the current state is the same as what upstream pointed to. So, a new tag in upstream will create a new tag in the fork, unless you have a tag of the same name, when the update will fail.

Manual syncing

If upstream and your fork have diverged, so that each has changes that are not in the other, Stash will not perform a merge automatically. When you visit the branch within Stash, you have the option to manually synchronize the branch.

You can manually synchronize your branch at any time using Synchronize on either of the 'Files' or 'Commits' tabs for a repository:
Manual synchronization strategies

When you initiate a manual synchronization, Stash ask you to choose one of the following synchronization strategies.

**Merge strategy**

Merge the upstream branch into the fork branch.

If Stash detects conflicts when trying to perform the merge it will offer hints on how to resolve those:
Once the merge is complete, your branch will have incorporated all the commits on the branch in the parent repository, but your branch will still be ahead of the parent (it has your changes on it). This means automatic synchronization for this branch will not occur until your changes are pushed to the parent repository.

**Discard strategy**

Overwrite your changes in your fork with the upstream branch. Your changes will be lost.

**Using pull requests in Stash**

Pull requests in Stash provide the team with a quick and easy way to review changes made on a branch, discuss those changes, and make further modifications before the branch is merged back to master or your main development branch.

Creating a pull request

When you are ready to start a discussion about your code changes, simply create a pull request.

To create a pull request:

1. Go to the repository in Stash.
2. Click **Pull Request** at the top of the page.
3. Choose the source and destination branches. The source branch is where you made your changes and the destination is the branch you want to merge to. The source and target branches may be located in different forks.
4. Enter a title and description that will help people understand what your pull request is about. You can use mentions (to notify another Stash user), and markdown (to add formatting) in your description.

5. Add reviewers – they will receive a notification by email. Other people who have permissions on the project can participate in the discussion if it interests them.

6. Click Create pull request.
You will receive email notifications when your reviewers and other participants comment on the pull request, or commit changes to it.

Editing a pull request
After creating the pull request, you can modify it later by clicking Edit on the pull request's page. You can edit details such as the Title, Description and the Reviewers. In particular, you can change the Destination branch for the pull request – you'll need Read permission on the branch you want to set.

Discussing a pull request
The most important thing about a pull request is the discussion that it generates. To help you contribute to the discussion, Stash organises all the information about the pull request into 3 tabs. From a project repository page, click Pull requests, then click on a particular pull request.

Participants can commit new changes to the branch. Stash auto-updates the Commits tab of the pull request, so you can see exactly which commits will be merged. Stash is smart about comments, moving them along when lines are added or removed. If a line with a comment gets removed, you can still view the comment in the activity, but Stash marks the diff as outdated to let you know that this piece of code has been changed in recent commits.

Overview

The Overview tab captures all of the team's activity on the pull request in one place, right from the initial creation, through to when it is finally merged (or declined), with all the comments, replies and commits that happen along the way.

You can add a comment on the Overview tab (above the activity), or reply to a previous comment. Use mentions to alert another Stash user to your comment, and use markdown to add formatting, for example headings or lists.

Diff

Diffs for Stash pull requests provide the following advantages:

- The diff highlights the changes that will result when the merge occurs, so you can see exactly what the effect of the merge will be.
- The diff tree on the left colour-codes files that have been added, changed or deleted, so you can quickly see the files you may need to review.
- As you'd expect, the diff for a file shows which lines of code have been added, deleted or modified.
- You can comment on the whole file by clicking the icon on the right in the diff header.
- You can comment directly on a line of code right in the diff, by hovering over the line, clicking the icon at the left, and entering your comment. Your comment will also appear in the activity.
- Comments in the diff are threaded, to allow meaningful and contextual conversations about your code.

Commits

The Commits tab lists all the commits that will get merged.

Note that clicking through to a commit takes you out of the pull request context; you can comment on the whole file, or a particular line of code, for any file in the commit.

JIRA issues integration

When Stash is integrated with JIRA you can see the related JIRA issues right in the pull request. You'll see either the JIRA issue key, when there is just one, or the number of related issues:
Click an issue key to see details of the issue, such as the description, status and assignee, without having to leave Stash:

Click the issue key to see the issue in JIRA. This allows reviewers to gain important insight into the task that is being worked on, by seeing the comments and attachments on the issue. This also gives access into JIRA, so you can easily keep issues updated.

Merging a pull request

Once you are ready to merge a pull request, and when the reviewers have approved it, simply click Merge at the top right of the pull request view. You can merge a pull request if you have write (or admin) permission on the project.

Stash does not enforce particular review workflows, so, for example, anyone with write permission on the repository can merge a pull request, including the person who opened it. This flexibility allows different teams to have different approaches to using Stash. If your team requires stricter control, consider using branch
permissions to restrict who can merge a pull request to particular users or groups. You might also want to consider using a plugin to enforce a particular workflow, for example to ensure that only approvals from members of your review team allow merging. See Checks for merging pull requests.

In the 'Merge Pull Request' dialog, you can check Delete branch if you no longer need that branch in the repository. Stash checks on a few things before allowing the deletion – the branch being merged will not be deleted if:

- The branch is the default repository branch.
- The user does not have permission to delete the branch.
- The branch is subject to an open pull request.

Once accepted, the pull request is marked as merged on the Pull requests tab.

If Stash detects a conflict that prevents the merge, notifications are displayed on the Overview and Diff tabs of the pull request. Click More information to see instructions for how to resolve the conflict in your local repository.

Watching and notifications

You automatically get added as a watcher of a pull request when you perform an action related to the pull request, such as adding a comment. You can manually add yourself as a watcher by clicking the Watch button on the pull request screen.

You can always stop watching a pull request by clicking the link in the email notification, or the Unwatch button on the pull request screen. If you stop watching a pull request you will not automatically be added as a watcher again if you subsequently perform an action that would otherwise have added you.

Stash sends email notifications to watchers when certain events occur. See Notifications for details.

Checks for merging pull requests

To help customise your workflow, you can set checks to control when a pull request can be merged. Pull requests cannot be merged if the required checks have not been met. These checks are set separately on each repository in a Stash project.

You'll need either project admin, admin or sys-admin permissions to set merge checks for pull requests.

So, to set merge checks for pull requests, go to a repository in a project and choose Settings > Pull requests. Stash includes the merge checks described below, or you can write your own merge request check plugin.

Require a number of completed builds
Select this option to stop pull requests from being merged if they have any unsuccessful builds. For a pull request, this checks builds that run against the latest commit on the source branch.

You must also specify a minimum number of builds - the pull request will not be able to be merged until at least this many builds have completed. Ideally, you should set this to the number of different builds that are configured to run against the branches in your repository.

See Bamboo integration for more information about integrating Stash with your build server.

Permanently authenticating with Git repositories

In addition to SSH, Stash supports HTTP or HTTPS for pushing and pulling from managed Git repositories. However, Git has no method of caching the user’s credentials, so you need to re-enter them each time you perform a clone, push or pull.
This page describes two methods for permanently authenticating with Git repositories so that you can avoid typing your username and password each time you are pushing to or pulling from Stash.

On this page:

- Using credential caching
- Using the `.netrc` file

## Using credential caching

⚠️ You need Git 1.7.9 or above to use the HTTPS Credentials Caching feature.

### Windows

On Windows you can use the application `git-credential-winstore`.

1. Download the software.
2. Run it.
3. You will be prompted for credentials the first time you access a repository, and Windows will store your credentials for use in the future.

### Linux

On Linux you can use the 'cache' authentication helper that is bundled with Git 1.7.9 and higher. From the Git documentation:

>This command caches credentials in memory for use by future git programs. The stored credentials never touch the disk, and are forgotten after a configurable timeout. The cache is accessible over a Unix domain socket, restricted to the current user by filesystem permissions.

Run the command below to enable credential caching. After enabling credential caching any time you enter your password it will be cached for 1 hour (3600 seconds):

```
git config --global credential.helper 'cache --timeout 3600'
```

Run the command below for an overview of all configuration options for the 'cache' authentication helper:

```
git help credential-cache
```

### OSX

Follow these steps to use Git with credential caching on OSX:

1. Download the binary `git-credential-osxkeychain`.
2. Run the command below to ensure the binary is executable:

```
chmod a+x git-credential-osxkeychain
```
3. Put it in the directory `/usr/local/bin`.
4. Run the command below:
Using the `.netrc` file

The `.netrc` file is a mechanism that allows you to specify which credentials to use for which server. This method allows you to avoid entering a username and password every time you push to or pull from Git, but your Git password is stored in plain text.

**Warning!**
- Git uses a utility called cURL under the covers, which respects the use of the `.netrc` file. Be aware that other applications that use cURL to make requests to servers defined in your `.netrc` file will also now be authenticated using these credentials. Also, this method of authentication is potentially unsuitable if you are accessing your Stash server via a proxy, as all cURL requests that target a path on that proxy server will be authenticated using your `.netrc` credentials.
- cURL will not match the machine name in your `.netrc` if it has a username in it, so make sure you edit your `.git/config` file in the root of your clone of the repository and remove the user and '@' part from any clone URL's (URL fields) that look like `https://user@machine.domain.com/...` to make them look like `http://machine.domain.com/...`

### Windows

1. Create a text file called `_netrc` in your home directory (e.g. `c:\users\kannonboy\_netrc`). cURL has problems resolving your home directory if it contains spaces in its path (e.g. `c:\Documents and Settings\kannonboy`). However, you can update your `%HOME%` environment variable to point to any directory, so create your `_netrc` in a directory with no spaces in it (for example `c:\curl-auth`) then set your `%HOME%` environment variable to point to the newly created directory.
2. Add credentials to the file for the server or servers you want to store credentials for, using the format described below:

   ```
   machine stash1.mycompany.com
   login myusername
   password mypassword
   machine stash2.mycompany.com
   login myotherusername
   password myotherpassword
   ```

### Linux or OSX

1. Create a file called `.netrc` in your home directory (~/.netrc). Unfortunately, the syntax requires you to store your passwords in plain text - so make sure you modify the file permissions to make it readable only to you.
2. Add credentials to the file for the server or servers you want to store credentials for, using the format described in the ‘Windows’ section above. You may use either IP addresses or hostnames, and you do not need to specify a port number, even if you’re running Stash on a non-standard port.
3. And that’s it! Subsequent `git clone`, `git pull` and `git push` requests will now be authenticated using the credentials specified in this file.

### Notifications

An email server must be configured in Stash for email notifications to be sent. See Setting up your mail server. Note that if the mail server fails, notifications will be dropped. See also HipChat notifications.

### Pull request notifications

Stash sends HTML email notifications to the watchers of a pull request when the following events occur:
### Pull request event

<table>
<thead>
<tr>
<th>Event</th>
<th>Notification sent</th>
</tr>
</thead>
<tbody>
<tr>
<td>A reviewer is added</td>
<td>✓</td>
</tr>
<tr>
<td>A comment is added</td>
<td>✓</td>
</tr>
<tr>
<td>A comment is edited</td>
<td>✓</td>
</tr>
<tr>
<td>A comment is replied to</td>
<td>✓</td>
</tr>
<tr>
<td>A commit is made to the source branch</td>
<td>✓</td>
</tr>
<tr>
<td>The pull request is approved</td>
<td>✓</td>
</tr>
<tr>
<td>The pull request is merged</td>
<td>✓</td>
</tr>
<tr>
<td>The pull request is declined</td>
<td>✓</td>
</tr>
<tr>
<td>The pull request is reopened</td>
<td>✓</td>
</tr>
</tbody>
</table>

Note that you don’t receive notifications for events you initiate yourself.

### Using 'mentions' to notify someone

From Stash 2.0 you can use 'mentions' to notify another Stash user about the pull request description or comment you are writing. Stash sends an email to that user.

To use mentions, simply start typing '@' and then the users display name, username or email address, and choose from the list that Stash offers. You can use quotes for unusual names, for example if it has spaces. Use Control-Shift-P or Command-Shift-P to preview the mention.

#### HipChat notifications

Stash can send an IM notification to a HipChat room whenever someone pushes to a repository. HipChat notifications are implemented as a post receive hook in Stash, and are available to all repos in Stash.

You can enable and disable HipChat notifications for a particular repo by going to Settings > Hooks for the repo:

You need to specify the API token and the name of the HipChat room:
Talk to your HipChat administrator to get the API token for your HipChat server.

Here's an example of what you might see, from our own HipChat room:

```
<table>
<thead>

```

**Markdown syntax guide**

By default, Stash uses **Markdown** as its markup language. You can use markdown in the following places:

- any pull request's descriptions or comments, or
- in README files (if they have the .md file extension).

Use **Control-Shift-P** or **Command-Shift-P** to preview your markdown.

**Markdown syntax**

The page below contains examples of Markdown syntax. For a full list of all the Markdown syntax, consult the official documentation on John Gruber's [Daring Fireball](https://daringfireball.net) site.

**Headings**

```markdown
# This is an H1
## This is an H2
### This is an H6
```
Paragraphs

Each paragraph begins on a new line. Simply press <return> for a new line.

For example, like this.

You'll need an empty line between a paragraph and any following markdown construct, such as an ordered or unordered list, for that to be rendered. Like this:

* Item 1
* Item 2

Character styles

*Italic characters*
_Italic characters_
**bold characters**
__bold characters__

Unordered list

* Item 1
* Item 2
* Item 3
  * Item 3a
  * Item 3b
  * Item 3c

Ordered list
List in list

1. Step 1
2. Step 2
3. Step 3
   a. Step 3a
   b. Step 3b
   c. Step 3c

Quotes or citations

Introducing my quote:

> Neque porro quisquam est qui
dolorem ipsum quia dolor sit amet,
consectetur, adipisci velit...

Inline code characters

Use the backtick to refer to a `function()`.

There is a literal `backtick` here.

Code blocks

Indent every line of the block by at least 4 spaces or 1 tab. Alternatively, you can also use 3 backtick quote marks before and after the block, like this:

````
Text to appear as a code block.
```

Within a code block, ampersands (&) and angle brackets (< and >) are automatically converted into HTML entities.

This is a normal paragraph:
   This is a code block.
   With multiple lines.

Links to external websites
Linking issue keys to JIRA

When you use JIRA issue keys (of the default format) in comments and pull request descriptions Stash automatically links them to the JIRA instance.

The default JIRA issue key format is two or more uppercase letters ([A-Z]+), followed by a hyphen and the issue number, for example STASH-123.

Images

Inline image syntax looks like this:

```
![Alt text](/path/to/image.jpg)
![Alt text](/path/to/image.png "Optional title attribute")
![Alt text](/url/to/image.jpg)
```

For example:

```
...
![Mockup for feature A](http://monosnap.com/image/bOcxxxxLGF.png)
...
```

Reference image links look like this:

```
![Alt text][id]
```

where 'id' is the name of a previously defined image reference, using syntax similar to link references:

```
[id]: url/to/image.jpg "Optional title attribute"
```

For example:

```
...
  <!--Collected image definitions-->
  [MockupA]: http://monosnap.com/image/bOcxxxxLGF.png "Screenshot of Feature A mockup"
  ...
  <!--Using an image reference-->
  ![Mockup for feature A][MockupA]
  ...
```

Tables
<table>
<thead>
<tr>
<th>Day</th>
<th>Meal</th>
<th>Price</th>
</tr>
</thead>
<tbody>
<tr>
<td>Monday</td>
<td>pasta</td>
<td>$6</td>
</tr>
<tr>
<td>Tuesday</td>
<td>chicken</td>
<td>$8</td>
</tr>
</tbody>
</table>

You can also use HTML...

Inline HTML

An example, to add a table:

```
This is a regular paragraph.
<table>
  <tr>
    <td>Foo</td>
  </tr>
</table>
This is another regular paragraph.
```

Note that Markdown formatting syntax is not processed within block-level HTML tags. That is, you can’t use Markdown-style *emphasis* inside an HTML block.

See http://daringfireball.net/projects/markdown/syntax#html for more details.

**README files**

From Stash 1.3, you can document a project right in the repository by creating .md or .txt files. If the ReadMe has the .md extension, any Markdown it contains gets rendered straight to the screen when viewed from the file list of the repository.
Requesting add-ons

The Atlassian Marketplace website offers hundreds of add-ons that the administrator of your Atlassian application can install to enhance and extend Atlassian products, including Stash. If the add-on request feature is enabled for your Stash instance, you can submit requests for add-ons from the Marketplace to your Stash administrator.

The 'Atlassian Marketplace for Stash' page provides an integrated view of the Atlassian Marketplace from within your Stash instance. The page offers the same features as the Marketplace website, such as searching and category filtering, but tailors the browsing experience to Stash.

Atlassian Marketplace for Stash

Find and request powerful add-ons compatible with your Stash version on this streamlined Atlassian Marketplace. Manage add-ons.

This in-product view of the Marketplace gives day-to-day users of Atlassian applications, not just administrators, an easy way to discover add-ons that can help them get work done. When you find an add-on of interest, you can submit a request to your administrator for the add-on with just a few clicks.

Submitting an add-on request

To browse for add-ons in the Atlassian Marketplace, follow these steps:

1. From anywhere in the application, open your profile menu and choose Atlassian Marketplace:
2. In the Atlassian Marketplace page, use the search box to find add-ons or use the category menus to browse or filter by add-ons by type, popularity, price or other criteria. You can see what your fellow users have requested by choosing the Most Requested filter.

3. When you find an add-on that interests you, click Request to generate a request for your administrator.

4. Optionally, type a personal message to your administrators in the text box. This message is visible to administrators in the details view for the add-on.

5. Click Submit Request when done.

6. Click Close to dismiss the 'Success!' message dialog box.

At this point, a notification appears in the interface your administrators use to administer add-ons. Also your request message will appear in the add-on details view, visible from the administrator's 'Find New Add-ons' page. From there, your administrator can purchase the add-on, try it out or dismiss requests.

**Updating an add-on request**

After submitting the request, you can update your message at any time. Click the Update Request button next to the listing in the Atlassian Marketplace page to modify the message to your administrator.

The administrator is not notified of the update. However, your updated message will appear as you have modified it in the details view for the add-on immediately.

**Integrating Stash with Atlassian applications**

When you integrate Stash with Atlassian applications you get the following benefits:
<table>

JIRA integration

When Stash is integrated with Atlassian JIRA, you and your team get all these benefits:

- See all the related commits, branches and pull requests in a JIRA issue.
- Create Git branches from within JIRA and JIRA Agile.
- Transition JIRA issues from within Stash.
- Use JIRA issue keys in Stash markdown.
- See the details for JIRA issues in Stash.
- See the JIRA issues related to Stash commits and pull requests.
- See all the files committed for the issue (on the JIRA Source tab).
- From JIRA, click through to see a changed file, or the full commit, in Stash.

Create Git branches from within JIRA and JIRA Agile

You can start creating a branch from a JIRA issue. This gives you a faster workflow from picking an issue to starting coding.

Stash will suggest the branch type and branch name, based on the JIRA issue type and summary – you can change these, of course.

Transition JIRA issues from within Stash

You can easily transition a JIRA issue from within Stash. For example, when creating a pull request you may want to transition the issue into review. Click on a linked JIRA issue anywhere in Stash to see a dialog with the available workflow steps:

Click on a step and complete the fields as required. If there are custom fields that are unsupported by Stash, just click Edit this field in JIRA to transition the issue directly in JIRA.

See issues from multiple instances of JIRA

Stash can link to more than one JIRA server at a time, so different teams can work with their own projects in different JIRA instances, or a single team can link to issues across multiple JIRA servers.

Use JIRA issue keys in markdown

When you mention a JIRA issue key in Stash, for example in a pull request description or a comment, the key gets automatically linked:

Created in 2014 by Atlassian. Licensed under a Creative Commons Attribution 2.5 Australia License.
Click on the linked key to see details for the issue.

See the details for JIRA issues

Click a linked issue key anywhere in Stash to see the details of that issue in a dialog. And you can just click the issue key at the top of the dialog to go straight to the issue in JIRA:

See the JIRA issues related to commits and pull requests

Stash recognises JIRA issue keys in commit messages, and displays the keys as links on the Commits tabs for both the repository and pull requests:

Click on the linked key to see details for the issue.

See details of Stash commits in JIRA

In JIRA, you can see details for a commit made in Stash. And you can click through to go straight to the commit in Stash:
Bamboo integration

When Stash is integrated with a build server such as Atlassian's Bamboo, build results are published to Stash. You see the build results status for a commit when viewing any commit or pull request. This lets you easily check the build status of a branch when deciding whether to merge the changes.

Stash displays the overall status of the build results. The status is 'passed' if all the different builds (for example, unit tests, functional tests, deploy to staging) have succeeded, and 'failed' if at least one run failed for any of those.

Related pages:
- JIRA integration
- Using pull requests in Stash

For example, when viewing the Commits tab for a Stash project, you will see icons that indicate the status of the latest build results. The red fail icon is displayed if there is at least one failed build run for the commit:

Click a build status icon to see further details:
The information that you see in this dialog is specific to the build server that provides it, in this example Bamboo.

Integration of Bamboo build results in Stash is entirely configured on the Bamboo server. See Integrating Bamboo with Stash.

You can also use the Stash Rest API to automatically publish build status from Bamboo, Jenkins or any other build tool to Stash. See the Stash developer documentation to do with updating build status.

Administering Stash

This section describes some of the administrative actions that can be performed from the Stash Administration user interface (get there by clicking the ‘cog’ icon in the Stash header).

In this section:

- Users and groups
- Global permissions
- JIRA integration
  - JIRA FishEye-Stash Plugin compatibility
- External user directories
  - Configuring an LDAP directory
  - Configuring delegated LDAP authentication
  - Connecting to Crowd
  - Connecting Stash to JIRA for user management
- Setting up your mail server
- Specifying the base URL for Stash
- Connecting Stash to an external database
- Enabling SSH access to Git repositories in Stash

Related pages:

- Supported platforms
- Using Stash
- Stash FAQ

System administration advanced actions that can be performed outside of the Stash user interface include:

- Setting up SSH port forwarding
- Moving Stash to a different context path
- Running Stash with a dedicated user
- Securing Stash with Tomcat using SSL
Users and groups

Stash comes with an internal user directory already built-in that is enabled by default at installation. When you create the first administrator during the setup procedure, that administrator’s username and other details are stored in the internal directory.

Stash Admins and Sys Admins can manage users and groups in Stash as described on this page. You can also set up Stash to use external user directories.

Note that:

- Even after users have been added to the Stash user directory, they will not be able to log in to Stash until they have been given global access permissions.
- Permissions can also be applied separately at the level of projects, repositories and branches.

On this page:

- Creating a user
- Creating a group
- Adding users to groups
  - From the user account page
  - From the group page
- Changing usernames
- Deleting users and groups

Related pages:

Creating a user

In the administration area, click Users (under ‘Accounts’) and then Create user (on the ‘Users’ screen)
Complete the form. You can either set the user’s password now, or have Stash email the user with a link that they can use to set the password themselves:

Once you've created the user, click **Change permissions** to set up their access permissions. Note that a user doesn't have access to Stash until global access permissions have been set.
Global permissions

Creating a group

In the administration area, click Groups (under ‘Accounts’) and then Create group. Enter the name for the new group, and click Create group (again):

Adding users to groups

You can add users to groups in two ways:

- add a particular user to multiple groups, from the user’s account page in the admin area.
- add multiple users to a particular group, from the group's page.

From the user account page

To add a user to a group from the user’s account page, click Users in the Administration section, and then use the filter to find the user:
On the account page for the user, use the filter to find a group to which you want to add the user:

Click Add for each group in turn.

From the group page
To add a user to a group from the group's page, click Groups (under "Accounts") in the administration area, and use the filter to find the group:

On the page for the group, use the filter to find a user whom you wish to add to the group:
Click **Add** for each user you select, to make them a member of the group.

**Changing usernames**

You can change the username for a user account that is hosted in Stash's internal user directory. Go to **Users** in the Administration section, and use the filter to find the user. On the account page for the user, click **Rename**.

**Deleting users and groups**

You can delete a user or group from Stash's internal user directory, or the external directory from which Stash sources users, such as an LDAP, Crowd or JIRA server.

When a user or group is deleted from such a directory, Stash checks to see if that user still exists in another directory:

- If the user or group does exist in another directory, Stash assumes the administrator intended to **migrate** the user or group between directories and we leave their data intact.
- If the user or group does not exist in another directory, Stash assumes the intent was to permanently delete them, and we delete the users permissions, SSH keys and 'rememberme' tokens.

**Notes**

- If an entire directory is deleted Stash **always** assumes it is a migration and does nothing to clean up after users and groups.
- Content which might be of historical interest (comments, pull requests, etc.) is not deleted when a user or group is. Only authentication, authorisation and data which serves no purpose to a user who can no longer log in is removed.
- In some situations, reordering the directories will change the directory that the current user comes from, if a user with the same username happens to exist in both. This behaviour can be used in some cases to create a copy of the existing configuration, move it to the top, then remove the old one. Note, however, that duplicate usernames are not a supported configuration.
- You can enable or disable a directory at any time. If you disable a directory, your configuration details will remain but Stash will not recognise the users and groups in that directory.

**Limitations**

- You cannot edit, disable or delete the directory that your own user account belongs to. This prevents administrators from locking themselves out of Stash, and applies to internal as well as external directories.
- You cannot remove the internal directory. This limitation aligns with the recommendation that you always keep an administrator or sysadmin account active in the Stash internal directory, so that you can troubleshoot problems with your user directories.
You have to disable a directory before you can remove it. Removing a directory will remove the details from the database.

External user directories

You can connect Stash to external user directories. This allows you to use existing users and groups stored in an enterprise directory, and to manage those users and groups in one place.

User management functions include:

- **Authentication**: Determining which user identity is sending a request to Stash.
- **User management**: Maintaining core information about users accounts.
- **Group membership**: Storing and retrieving groups, and group membership.
- **Profile information**: Providing metadata associated with users.

It is important to understand that these are separate components of a user management system. You could use an external directory for any or all of the above tasks.

There are several approaches to consider when using external user directories with Stash, described briefly below:

- **LDAP**
- **JIRA**
- **Crowd**

You should consider connecting to an LDAP directory server if your users and groups are stored in an enterprise directory.

There are two common ways of using an external LDAP directory with Stash:

- For full user and group management, including for user authentication — see Connecting Stash to an existing LDAP directory for instructions.
- For delegated user authentication only, while using Stash's internal directory for user and group management — see Delegating Stash authentication to an LDAP directory for instructions.

Stash is able to connect to the following LDAP directory servers:

- Microsoft Active Directory
- Apache Directory Server (ApacheDS) 1.0.x and 1.5.x
- Apple Open Directory (Read-Only)

Connecting Atlassian Stash to your external directory is not sufficient to allow your users to log in to Stash. You must explicitly grant them access to Stash in the global permission screen.

We recommend that you use groups instead of individual accounts when granting permissions. However, be careful not to add more users to those groups that your Stash license allows. If the license limit is exceeded, your developers will not be able to push commits to repositories, and Stash will display a warning banner. See this FAQ.

Stash comes with an internal user directory, already built-in, that is enabled by default at installation. When you create the first administrator during the setup procedure, that administrator's username and other details are stored in the internal directory.

JIRA

You can delegate Stash user and group management, as well as user authentication, to an Atlassian JIRA instance. This is a good option if you already use JIRA in your organization. Note that Stash can only connect to a JIRA server running JIRA 4.3 or later.

You should consider using Atlassian Crowd for more complex configurations with a large number of users.

See Connecting Stash to JIRA for user management for configuration instructions.

Crowd

You can connect Stash to Atlassian Crowd for user and group management, as well as for user authentication.

Crowd is an application security framework that handles authentication and authorisation for your web-based applications. With Crowd you can integrate multiple web applications and user directories, with support for single sign-on (SSO) and centralised identity management. See the Crowd Administration Guide.

You should consider connecting to Crowd if you want to use Crowd to manage existing users and groups in multiple directory types, or if you have users of other web-based applications.

See Connecting Stash to Crowd for configuration instructions.

Connecting Stash to an existing LDAP directory

You can connect Stash to an existing LDAP user directory, so that your existing users and groups in an enterprise directory can be used in Stash. The LDAP directory is used for both user authentication and account management.

Stash is able to connect to the following LDAP directory servers:

- Microsoft Active Directory
- Apache Directory Server (ApacheDS) 1.0.x and 1.5.x
- Apple Open Directory (Read-Only)
- Fedora Directory Server (Read-Only Posix Schema)
- Novell eDirectory Server
- OpenDS
- OpenLDAP
- OpenLDAP (Read-Only Posix Schema)
- Generic Posix/RFC2307 Directory (Read-Only)
- Sun Directory Server Enterprise Edition (DSEE)
- Any generic LDAP directory server

See also this information about deleting users and groups in Stash.
License considerations

When connecting Stash to an external directory, be careful not to allow access to Stash by more users than your Stash license allows. If the license limit is exceeded, your developers will not be able to push commits to repositories, and Stash will display a warning banner. See this FAQ.

Synchronisation when Stash is first connected to the LDAP directory

When you first connect Stash to an existing LDAP directory, the Stash internal directory is synchronised with the LDAP directory. User information, including groups and group memberships, is copied across to the Stash directory.

When we performed internal testing of synchronisation with an Active Directory server on our local network with 10 000 users, 1000 groups and 200 000 memberships, we found that the initial synchronisation took about 5 minutes. Subsequent synchronisations with 100 modifications on the AD server took a couple of seconds to complete. See the option below.

Note that when Stash is connected to an LDAP directory, you cannot update user details in Stash. Updates must be done directly on the LDAP directory, perhaps using a LDAP browser tool such as Apache Directory Studio.

Option - Use LDAP filters to restrict the number of users and groups that are synchronised

You can use LDAP filters to restrict the users and groups that are synchronised with the Stash internal directory. You may wish to do this in order to limit the users or groups that can access Stash, or if you are concerned that synchronisation performance may be poor.

For example, to limit synchronisation to just the groups named "stash_user" or "red_team", enter the following into the Group Object Filter field (see Group Schema Settings below):

\&objectClass=group\&(cn=stash_user)\&(cn=red_team)\)

For further discussion about filters, with examples, please see How to write LDAP search filters. Note that you need to know the names for the various containers, attributes and object classes in your particular directory tree, rather than simply copying these examples. You can discover these container names by using a tool such as Apache Directory Studio.

Authentication when a user attempts to log in

When a user attempts to log in to Stash, once synchronisation has completed, Stash confirms that the user
exists in it's internal directory and then passes the user's password to the LDAP directory for confirmation. If the password matches that stored for the user, LDAP passes a confirmation back to Stash, and Stash logs in the user. During the user's session, all authorisations (i.e. access to Stash resources such as repositories, pull requests and administration screens) are handled by Stash, based on permissions maintained by Stash in its internal directory.

![Diagram of a user logging into Stash and then into LDAP]

**Connecting Stash**

**To connect Stash to an LDAP directory:**

1. Log in as a user with 'Admin' permission.
2. In the Stash administration area, click User Directories (under 'Accounts').
3. Click Add Directory and select either Microsoft Active Directory or LDAP as the directory type.
4. Configure the directory settings, as described in the tables below.
5. Save the directory settings.
6. Define the directory order by clicking the arrows next to each directory on the 'User Directories' screen.

   The directory order has the following effects:
   - The order of the directories is the order in which they will be searched for users and groups.
   - Changes to users and groups will be made only in the first directory where the application has permission to make changes.

### Port

The port on which your directory server is listening. Examples:

- 389
- 10389
- 636 (for example, for SSL)

### Use SSL

Check this if the connection to the directory server is an SSL (Secure Sockets Layer) connection. Note that you will need to configure an SSL certificate in order to use this setting.

### Username

The distinguished name of the user that the application will use when connecting to the directory server. Examples:

- `cn=administrator,cn=users,dc=ad,dc=example,dc=com`
- `cn=user,dc=domain,dc=name`
- `user@domain.name`

### Password

The password of the user specified above.

Read Only, with Local Groups

LDAP users, groups and memberships are retrieved from your directory server and can only be modified via your directory server. You cannot modify LDAP users, groups or memberships via the application administration screens. However, you can add groups to the internal directory and add LDAP users to those groups.

### Advanced settings

</tr>
<tr>
<td>Naive DN Matching</td>
<td>If your directory server will always return a consistent string representation of a DN, you can enable naive DN matching. Using naive DN matching will result in a significant performance improvement, so we recommend enabling it where possible. This setting determines how your application will compare DNs to determine if they are equal.</td>
</tr>
</tbody>
</table>

- If this checkbox is selected, the application will do a direct, case-insensitive, string comparison. This is the default and recommended setting for Active Directory, because Active Directory guarantees the format of DNs.
- If this checkbox is not selected, the application will parse the DN and then check the parsed version.
Enable Incremental Synchronisation | Enable incremental synchronisation if you only want changes since the last synchronisation to be queried when synchronising a directory.

⚠️ Please be aware that when using this option, the user account configured for synchronisation must have read access to:

- The `usNChanged` attribute of all users and groups in the directory that need to be synchronised.
- The objects and attributes in the Active Directory deleted objects container (see Microsoft's Knowledge Base Article No. 892806 for details).

If at least one of these conditions is not met, you may end up with users who are added to (or deleted from) the Active Directory not being respectively added (or deleted) in JIRA.

This setting is only available if the directory type is set to "Microsoft Active Directory".

</table>

Synchronisation Interval (minutes) | Synchronisation is the process by which the application updates its internal store of user data to agree with the data on the directory server. The application will send a request to your directory server every x minutes, where ‘x’ is the number specified here. The default value is 60 minutes.

Read Timeout (seconds) | The time, in seconds, to wait for a response to be received. If there is no response within the specified time period, the read attempt will be aborted. A value of 0 (zero) means there is no limit. The default value is 120 seconds.

Search Timeout (seconds) | The time, in seconds, to wait for a response from a search operation. A value of 0 (zero) means there is no limit. The default value is 60 seconds.

Connection Timeout (seconds) | This setting affects two actions. The default value is 0.

- The time to wait when getting a connection from the connection pool. A value of 0 (zero) means there is no limit, so wait indefinitely.
- The time, in seconds, to wait when opening new server connections. A value of 0 (zero) means that the TCP network timeout will be used, which may be several minutes.
| User Object Filter | The filter to use when searching user objects. Example:  
|                   | • (&(objectCategory=Person) (sAMAccountName=*))  
|                   | More examples can be found [here](#) and [here](#). |
| User Name Attribute | The attribute field to use when loading the username. Examples:  
|                    | • cn  
|                    | • sAMAccountName  
|                    | NB: In Active Directory, the 'sAMAccountName' is the 'User Logon Name (pre-Windows 2000)' field. The User Logon Name field is referenced by 'cn'. |
| User Name RDN Attribute | The RDN (relative distinguished name) to use when loading the username. The DN for each LDAP entry is composed of two parts: the RDN and the location within the LDAP directory where the record resides. The RDN is the portion of your DN that is not related to the directory tree structure. Example:  
|                        | • cn |
| User First Name Attribute | The attribute field to use when loading the user's first name. Example:  
|                         | • givenName |
| User Last Name Attribute | The attribute field to use when loading the user's last name. Example:  
|                        | • sn |
| User Display Name Attribute | The attribute field to use when loading the user's full name. Example:  
|                         | • displayName |
| User Email Attribute | The attribute field to use when loading the user's email address. Example:  
|                       | • mail |
| User Password Attribute | The attribute field to use when loading a user's password. Example:  
|                        | • unicodePwd |
| User Unique ID Attribute | The attribute used as a unique immutable identifier for user objects. This is used to track username changes and is optional. If this attribute is not set (or is set to an invalid value), user renames will not be detected — they will be interpreted as a user deletion then a new user addition.  
|                       | This should normally point to a UUID value. Standards-compliant LDAP servers will implement this as 'entryUUID' according to [RFC 4530](#). This setting exists because it is known under different names on some servers, e.g. 'objectGUID' in Microsoft Active Directory. |

Connecting Stash to JIRA for user management

⚠️ This page does not apply to JIRA OnDemand; you can't use JIRA OnDemand to manage your Stash users.

You can connect Stash to an existing Atlassian JIRA instance, to delegate Stash user and group management, and authentication. Stash provides a "read-only" connection to JIRA for user management. This means that users and groups, fetched from JIRA, can only be modified or updated in that JIRA server, rather than in Stash.

Choose this option as an alternative to Atlassian Crowd, for simple configurations with a limited number of users. Note that Stash can only connect to a JIRA server running JIRA 4.3 or later.

Connecting Stash and JIRA is a 3-step process:

1. Set up JIRA to allow connections from Stash.
2. Set up Stash to connect to JIRA.
3. Set up Stash users and groups in JIRA.

You can connect to JIRA either when you first run Stash, using the Setup Wizard, or at any time after setup is complete.

If using the Stash Setup Wizard to configure JIRA integration, we recommend that you make use of the automatic back-linking from JIRA to Stash.

⚠️ You need to be an administrator in both JIRA and Stash to do this.

See also this information about deleting users and groups in Stash.

Connecting Stash to JIRA

1. Set up JIRA to allow connections from Stash

   1. Log in as a user with the 'JIRA Administrators' global permission.
   2. For JIRA 4.3.x, select Other Application from the 'Users, Groups & Roles' section of the 'Administration' menu.
      For JIRA 4.4 or later, choose Administration > Users > JIRA User Server.
   3. Click Add Application.
   4. Enter the application name (case-sensitive) and password that Stash will use when accessing JIRA.
   5. Enter the IP address of your Stash server. Valid values are:
      - A full IP address, e.g. 192.168.10.12.
      - A wildcard IP range, using CIDR notation, e.g. 192.168.10.1/16. For more information, see the...
introduction to CIDR notation on Wikipedia and RFC 4632.

6. Click Save.

7. Define the directory order, on the ‘User Directories’ screen, by clicking the blue up- and down-arrows next to each directory. The directory order has the following effects:
   - The order of the directories is the order in which they will be searched for users and groups.
   - Changes to users and groups will be made only in the first directory where the application has permission to make changes.

2. Set up Stash to connect to JIRA

1. Log in to Stash as a user with ‘Admin’ permission.
2. In the Stash administration area click User Directories (under ‘Accounts’).
3. Click Add Directory and select Atlassian JIRA.
4. Enter settings, as described below.
5. Test and save the directory settings.
6. Define the directory order, on the ‘User Directories’ screen, by clicking the arrows for each directory. The directory order has the following effects:
   - The order of the directories is the order in which they will be searched for users and groups.
   - Changes to users and groups will be made only in the first directory where the application has permission to make changes.

3. Set up Stash users and groups in JIRA

In order to use Stash, users must be a member of the Stash-users group or have Stash global permissions.

Follow these steps to configure your Stash groups in JIRA:

1. Add the stash-users and stash-administrators groups in JIRA.
2. Add your own username as a member of both of the above groups.
3. Choose one of the following methods to give your existing JIRA users access to Stash:
   - Option 1: In JIRA, find the groups that the relevant users belong to. Add those groups as members of one or both of the above Stash groups.
   - Option 2: Log in to Stash using your JIRA account and go to the administration area. Click Global permissions (under ‘Accounts’). Assign the appropriate permissions to the relevant JIRA groups. See Global permissions.

Connecting Atlassian Stash to JIRA for user management is not sufficient, by itself, to allow your users to log in to Stash. You must also grant them access to Stash by using one of the above 2 options.

We recommend that you use groups instead of individual accounts when granting permissions. However, be careful not to add more users to those groups that your Stash license allows. If the license limit is exceeded, your developers will not be able to push commits to repositories, and Stash will display a warning banner. See this FAQ.

**Delegating Stash authentication to an LDAP directory**

You can configure Stash to use an LDAP directory for delegated user authentication while still using the internal Stash directory for user and group management.

There is an option to automatically create a user account in Stash's internal directory when the user attempts to log in, as described in the Copy users on login section below.

See also this information about deleting users and groups in Stash.

**To connect Stash to an LDAP directory for delegated authentication:**

1. Log in to Stash as a user with 'Admin' permission.
2. Go to the Stash administration area and click **User Directories** (under 'Accounts').
3. Click **Add Directory** and select **Internal with LDAP Authentication** as the directory type.
4. Configure the directory settings, as described in the tables below.
5. Save the directory settings.
6. Define the directory order by clicking the arrows for each directory on the 'User Directories' screen. The directory order has the following effects:
   - The order of the directories is the order in which they will be searched for users and groups.
- Changes to users and groups will be made only in the first directory where the application has permission to make changes.

Connecting Atlassian Stash to your external directory is not sufficient to allow your users to log in to Stash. You must explicitly grant them access to Stash in the global permission screen.

We recommend that you use groups instead of individual accounts when granting permissions. However, be careful not to add more users to those groups that your Stash license allows. If the license limit is exceeded, your developers will not be able to push commits to repositories, and Stash will display a warning banner. See this FAQ.

| Default Group Memberships    | This field appears if you check the **Copy User on Login** box. If you would like users to be automatically added to a group or groups, enter the group name(s) here. To specify more than one group, separate the group names with commas. Each time a user logs in, their group memberships will be checked. If the user does not belong to the specified group(s), their username will be added to the group(s). If a group does not yet exist, it will be added to the internal directory that is using LDAP for authentication. Please note that there is no validation of the group names. If you mis-type the group name, authorisation failures will result – users will not be able to access the applications or functionality based on the intended group name. Examples:  
  - `confluence-users`
  - `bamboo-users,jira-users,jira-developers` |
Synchronise Group Memberships

This field appears if you select the Copy User on Login checkbox. If this box is checked, group memberships specified on your LDAP server will be synchronised with the internal directory each time the user logs in.

If you check this box the following additional fields will appear on the screen, both described in more detail below:

- Group Schema Settings (described in a separate section below)
- Membership Schema Settings (described in a separate section below)

Alternatively, you can move the delegated authentication directory to the top of the User Directories list and create the user manually (go to Administration > Users > Create user). Using this manual method you must currently create a junk password when creating users: there is an improvement request to address this. Please log in and vote for

Use the User Membership Attribute, when finding the user’s group membership

Check this box if your directory server supports the group membership attribute on the user. (By default, this is the ‘memberOf’ attribute.)

- If this box is checked, your application will use the group membership attribute on the user when retrieving the members of a given group. This will result in a more efficient retrieval.
- If this box is not checked, your application will use the members attribute on the group (‘member’ by default) for the search.

Connecting Stash to Crowd

You can configure Stash to use Atlassian Crowd for user and group management, and for authentication.

Atlassian Crowd is an application security framework that handles authentication and authorisation for your web-based applications. With Crowd you can integrate multiple web applications and user directories, with support for single sign-on (SSO) and centralised identity management. See the Crowd Administration Guide.

Connect to Crowd if you want to use Crowd to manage existing users and groups in multiple directory types, or if you have users of other web-based applications.

See also this information about deleting users and groups in Stash.

---

Connecting Atlassian Stash to your external directory is not sufficient to allow your users to log in to Stash. You must explicitly grant them access to Stash in the global permission screen.

We recommend that you use groups instead of individual accounts when granting permissions. However, be careful not to add more users to those groups that your Stash license allows. If the license limit is exceeded, your developers will not be able to push commits to repositories, and Stash will display a warning banner. See this FAQ.

To connect Stash to Crowd:

1. Log in as a user with ‘Admin’ permission.
2. In the Stash administration area, click User Directories (under ‘Accounts’).
3. Click Add Directory and select Atlassian Crowd.
4. Enter settings, as described below.
5. Test and save the directory settings.
6. Define the directory order, on the ‘User Directories’ screen, by clicking the blue up- and down-arrows next to each directory. The directory order has the following effects:
   - The order of the directories is the order in which they will be searched for users and groups.
   - Changes to users and groups will be made only in the first directory where the application has permission to make changes.

Name

A meaningful name that will help you to identify this Crowd server amongst your list of directory servers. Examples:

- Crowd Server
- Example Company Crowd

Server URL

The web address of your Crowd console server. Examples:

- http://www.example.com:8095/crowd/
- http://crowd.example.com

Application Name

The name of your application, as recognised by your Crowd server. Note that you will need to define the application in Crowd too, using the Crowd administration Console. See the Crowd documentation on adding an application.

Application Password

The password which the application will use when it authenticates against the Crowd framework as a client. This must be the same as the password you have registered in Crowd for this application. See the Crowd documentation on adding an application.

Crowd permissions

Stash offers Read Only permissions for Crowd directories. The users, groups and memberships in Crowd directories are retrieved from Crowd and can only be modified from Crowd. You cannot modify Crowd users, groups or memberships using the Stash administration screens.

For local Stash directories, Read Only and Read/Write permissions are available.

Single sign-on (SSO) with Crowd

Once the Crowd Directory has been set up, you can enable Crowd SSO integration by adding the following setting to `<STASH_HOME>/stash-config.properties`:
### stash-config.properties

# Whether SSO support should be enabled or not. Regardless of this setting SSO authentication will only be activated when a Crowd directory is configured in Stash that is configured for SSO.

plugin.auth-crowd.sso.enabled=true

Please note that you will need to correctly set up the domains of the applications involved in SSO. See Crowd SSO Domain examples

In addition to this property, Crowd SSO integration can be tuned through the following properties, all set in stash-config.properties. The configuration properties and their default values are displayed below:

<table>

User accounts that have not been assigned “Stash User” permission or higher, either directly or through group membership, will not be able to log in to Stash. These users are considered unlicensed and do not count towards your Stash license limit.

A user's permission level is displayed on the user's page seen from the admin area.

Note that you can also apply access permissions to projects.

1. Click the ‘cog’ menu in the header, to go to the admin area.
2. Click Global permissions (under ‘Accounts’).
3. Select, or clear, the permission checkboxes as required.
4. Click in the Add Users or Add Groups field to set permissions for additional users or groups.

You can remove all permissions for a user or group by clicking the X at the right-hand end of the row. This will remove the row.
Setting up your mail server

Setting up Stash to use your SMTP mail server:

- allows Stash to send notifications about events to do with pull requests. See Using pull requests in Stash. Note that if the mail server fails, notifications will be dropped.
- allows Stash to email a link to a newly created user, which the user can use to generate their own password.
- allows a user to reset his or her password if they forget it.

To configure a mail server for Stash, go to the administration area and click Mail server (under 'Settings'). See Supported platforms for the mail clients supported by Stash.

Fill in the form and click Save.

**Linking Stash with JIRA**

See [JIRA integration](#) for a description of all the integrations you get when Stash is linked with JIRA.

You can also use JIRA for delegated user management. See [External user directories](#).

This page describes how to link Stash to JIRA.

**On this page:**

- Linking Stash with JIRA instances
- Restrictions for JIRA integration
- Known issues with JIRA integration
- Troubleshooting integration with JIRA

**Related pages:**

Linking Stash with JIRA instances

You can integrate Stash with one or more instances of JIRA by means of ‘application links’. You set up application links either:

- during the Stash install process, using the Setup Wizard, or
- at any time after installation, as described below.

Note that integrating Stash with JIRA may require an upgraded version of the FishEye/Stash plugin in JIRA. See JIRA FishEye-Stash Plugin compatibility for details about upgrading the JIRA FishEye/Stash plugin, and for download links to the upgraded plugin versions.

To link Stash to a JIRA server:

1. Click Application Links (under ‘Settings’) in the Stash admin area.
2. Enter the URL for the JIRA instance you want to link to and click Create new link.
3. Complete the application link wizard to connect Stash to your JIRA server. You must make use of the automatic link-back from JIRA to Stash to get full integration (you’ll need JIRA system administrator global permission for that).

You're finished! Your JIRA issues will appear in the changesets and commit lists in Stash. On the JIRA side, the commits associated with a specific issue will now appear in the issue’s Source tab. Note that Stash only begins scanning commit messages for JIRA issue keys on the first push after you created the application link to JIRA – the scan may take a short time.

More detailed information about application links can be found on Configuring Application Links.

Restrictions for JIRA integration

- The display of details for JIRA issues, for example when viewing a pull request, relies on the JIRA 5.0 REST API. Issue details are not displayed when Stash in integrated with JIRA versions earlier than 5.0.
- Transitioning JIRA issues requires Trusted Apps or OAuth AppLinks. If only a Basic Auth applink is set up, users will be able to view issue details, but will not be able to transition issues.
- JIRA permissions are respected, so a user who is not permitted to transition an issue in JIRA will not see the transition buttons in Stash.

Known issues with JIRA integration

We have tried to make the integration of JIRA with Stash as straightforward as possible. However, we are aware of the following issue:

- There is no checking for project or issue-key validity: Stash may link to issues that do not actually exist:

  ![STASH-2470 - JIRA Integration: Check for issue validity before linking issues](opened)

We apologise for the inconvenience. Please watch the issue to keep track of our progress.

Troubleshooting integration with JIRA

There are a few scenarios where the integration of Stash with JIRA can produce an error:

The application link is misconfigured

This can result if authentication for the application link has not been set up. See Troubleshooting JIRA Integration.

You don’t have permission to access the JIRA project

If you don’t have permission to access the JIRA project then Stash is unable to display issues.

The JIRA server is of an unsupported version

Stash can integrate with JIRA 4.3.x, or later. Some features require higher versions of JIRA to function properly. See Integrating Stash with Atlassian applications for details.
The JIRA issue key is invalid
Stash doesn't check for invalid issue keys, such as UTF-8. An error will result if Stash tries to connect to an issue that doesn't exist.

The JIRA issue keys are of a custom format
Stash assumes that JIRA issue keys are of the default format (that is, two or more uppercase letters ([A-Z] [A-Z]+), followed by a hyphen and the issue number, for example STASH-123). By default, Stash will not recognise custom JIRA issue key formats. See Using custom JIRA issue keys with Stash for details.

The Application Link is created with OAuth only without the option to create a link using Trusted Applications
Stash allows a user with global permissions of "Administrator" to create an OAuth only application link. You need to log in with a user having "System Administrator" privileges to create an application link using Trusted Applications.

JIRA FishEye-Stash Plugin compatibility
Some aspects of Atlassian JIRA’s support for Stash is built into the FishEye/Stash Plugin that is bundled with JIRA. The plugin allows you to see all of your code changes in one place, even if you’re running multiple Atlassian FishEye and Stash servers.

The information on this page applies to Stash versions 2.1 and later.

Supported JIRA versions
If you’re using a version of JIRA earlier than 5.0.3 you may need to upgrade the FishEye/Stash plugin in JIRA to get support for Atlassian Stash.

Limited support for JIRA 4.4.x and earlier
JIRA 4.3+ allows for showing commits associated with issues in JIRA. However, viewing issues within Stash is not supported for JIRA 4.4.x and earlier.

Plugin upgrade guide

To upgrade the FishEye/Stash Plugin, copy the link from the table above that matches your JIRA version. Then navigate in JIRA to Administration > Plugins.

Next, select the Install Plugins tab and click Upload Plugin.

Now paste the URL copied from the table above into the From this URL field, and click Upload.
You should see that the plugin is installed. Now you can continue integrating Atlassian Stash with your JIRA server. See JIRA integration for details.

**JIRA 4.3.x Upgrade Note**

When upgrading the plugin in JIRA 4.3.x you may see a "zip file closed" error message in the logs. This can be ignored. See "IllegalStateException: zip file closed" when upgrading JIRA FishEye/Stash Plugin in JIRA 4.3 for more details.

**Using custom JIRA issue keys with Stash**

Stash assumes that JIRA issue keys are of the default format (that is, two or more uppercase letters ([A-Z][A-Z]+), followed by a hyphen and the issue number, for example STASH-123). By default, Stash will not recognise custom JIRA issue key formats.

You can use custom JIRA issue key formats with Stash, however note that integrations with JIRA can depend on using the default issue key format in both JIRA and Stash. See Integrating using custom JIRA issue keys for more details.

Configure Stash to recognize custom issue key formats by editing `<Stash installation directory>/bin/setenv.sh` (on Windows, edit `<Stash installation directory>/bin/setenv.bat` instead).

To override the default issue key format, use the JVM_SUPPORT_RECOMMENDED_ARGS property, like this:

```
Stash 2.8, and later:

JVM_SUPPORT_RECOMMENDED_ARGS="-Dintegration.jira.key.pattern="(<Some different regex>)"
```
Stash versions up to 2.7.x:

```
JVM_SUPPORT_RECOMMENDED_ARGS="-Dstash.jira.key.pattern="(\<Some different
regex\>)"
```

Notice that the parameter name was changed for Stash 2.8.

You will need to restart Stash.

For example, to use lowercase letters in issue keys, use a regex with the parameter like this:

Stash 2.8, and later:

```
"-Dintegration.jira.key.pattern="(?!([a-z]{1,10})-[?][a-z]+-[d])"
```

Stash versions up to version 2.7.x:

```
"-Dstash.jira.key.pattern="(?!([a-z]{1,10})-[?][a-z]+-[d])"
```

See also Reindex JIRA issue keys.

As always, please back up your home directory (and perhaps the database) before performing any manual operation on Stash. Consider testing this change on another copy of Stash before using it in production.

## Connecting Stash to an external database

This page provides information about using Stash with an external database.

Stash ships with an embedded database that it uses straight out-of-the-box, with no configuration required. This is great for evaluation purposes, but for production installations we recommend that you use one of the supported external databases.

Stash supports the following external databases:

- MySQL
- Oracle
- PostgreSQL
- SQL Server

Please refer to Supported platforms for the versions of external databases supported by Stash.

You can configure Stash to use an external database using:

- The Setup Wizard (when you install Stash); or
- The Database Migration Wizard in a running instance of Stash.

On this page:

- Why would I want to use an external database?
- Using the Setup Wizard to configure Stash to use an external database
- Using the Database Migration Wizard
- Notes about database migration
Why would I want to use an external database?

Stash ships with an embedded database that is great for evaluation purposes, but for production installations we recommend that you make use of one of the supported external databases, for the following reasons:

- **Improved protection against data loss**: The Stash built-in database, which runs HSQLDB, is susceptible to data loss during system crashes. External databases are generally more resistant to data loss during a system crash. HSQLDB is not supported in production environments and should only be used for evaluation purposes.

- **Performance and scalability**: If you have a large number of users on your Stash instance, running the database on the same server as Stash may slow it down. When using the embedded database, the database will always be hosted and run on the same server as Stash, which will limit performance.

- **Unified back-up**: Use your existing DBMS tools to back up your Stash database alongside your organisation's other databases.

Using the Setup Wizard to configure Stash to use an external database

You can connect Stash to an external database when you run the Setup Wizard, immediately after starting Stash for the first time. See Installing Stash on Windows or Installing Stash on Linux and Mac for more information.

If you have been using Stash for a while using the embedded database, you can migrate to an external database, as described below.

Using the Database Migration Wizard

You can use the Database Migration Wizard to migrate Stash from the embedded database to an external database, or from an external database to another external database. You need to have created the DBMS (such as MySQL) that you wish to migrate the Stash data to before running the Migration Wizard.

To run the Database Migration Wizard:

1. Log in to Stash.
2. In the administration area, click **Database** (under ‘Settings’).
3. Click **Migrate database** and follow the instructions for running the migration.

Notes about database migration

- **Back up the database and Stash home directory**: Before starting the database migration process you should back up your Stash home directory. If you intend to migrate from one external database to another, you should also backup the existing database before proceeding. See Data recovery and backups for more information.

- **Stash will be unavailable during the migration**: Stash will not be available to users during the database migration operation. In addition, running the migration when people are using Stash can sometimes cause the migration to time out waiting for all activity in Stash that uses the database to complete. For these reasons we recommend that you run the database migration outside of normal usage periods.

- **Migration will usually take less that 30 minutes**: The duration of the migration process depends on the amount of data in the Stash database being migrated. For new installations of Stash, containing very little data, the migration process typically takes just a few seconds. If you have been using Stash for some time, its database will contain more data, and the migration process will therefore take longer. If Stash has been linked to a JIRA instance, and there are hundreds of thousands of commits in Stash with JIRA keys in the commit messages, the migration
may take tens of minutes.

- **We strongly recommend using a new clean database for the new Stash database:**
  In case of a migration failure, Stash may have partially populated the target database. If the target
database is new (therefore empty) and set aside for Stash's exclusive use, it's very easy to clean up after
a failed migration; just drop the target database and use a clean target database instance for the next
attempt.

- **Ensure your Stash home directory is secured against unauthorised access:**
  - After the migration, the connection details (including the username and password) for the database
    are stored in the `stash-config.properties` file.
  - Migration will create a dump file of the contents of your database in the Stash home export direct-
    ory. This is used during the migration and is kept for diagnostic purposes in the case of an error. You
    may remove this after migration but it may reduce Atlassian Support's ability to help you in the
    case of migration issues.

- You can edit the database password if needed after migration.

**Connecting Stash to MySQL**

This page describes how to connect Stash to a MySQL database.

**MySQL 5.6.x Compatibility**

Note that Stash is not compatible with versions of MySQL 5.6 earlier than 5.6.16 because of bugs in its
query optimizer ( #68424, #69005 ). Please watch STASH-3164 for further updates on this. Stash does
support versions of MySQL 5.6 from 5.6.16 on.

See Supported platforms for the versions of MySQL supported by Stash.

The overall process for using a MySQL database with Stash is:

- Install MySQL where it is accessible to Stash.
- Create a database and user on the MySQL server for Stash to use.
- Install Stash on Windows, or on Linux or Mac.
- Either:
  - at Stash install time, run the Setup Wizard to connect Stash to the MySQL database, or
  - at a later time, migrate Stash to the MySQL database.

It is assumed here that you already have MySQL installed and running. MySQL documentation is available at http://dev.mysql.com/doc/.

**Prerequisites**

*Download and install the JDBC driver*

The JDBC drivers for MySQL are not bundled with Stash (due to licensing restrictions). You need to download
and install the driver yourself.

1. Download the MySQL Connector/J JDBC driver from the download site.
2. Expand the downloaded zip/tar.gz file.
3. Copy the mysql-connector-java-5.1.XX-bin.jar file from the extracted directory to your `<Stash home
directory>/lib` directory (for Stash 2.1 or later).
4. Stop Stash, on Windows, or on Linux and Mac.
5. Restart Stash, on Windows, or on Linux and Mac.

**Backup your data**
If you are migrating your data from the internal Stash database, back up the Stash home directory.

If you are migrating your Stash data from another external database, back up that database by following the instructions provided by the database vendor before proceeding with these instructions.

See Data recovery and backups.

Create the Stash database

Before you can use Stash with MySQL, you must set up MySQL as follows:

- configure the database to use the InnoDB storage engine
- create a database on MySQL for Stash to use
- create a Stash user on the database
- configure the database to use utf8 character set encoding. (Note that Stash on MySQL does not support 4 byte UTF-8 characters.)
- configure the database to use utf8_bin collation (to ensure case sensitivity)
- If MySQL is using binary logging, configure the database to use a binary logging format of either MIXED or ROW. Refer to the MySQL documentation. Note that Stash sets the MySQL transaction isolation level to READ-COMMITTED when it connects to the database.
- Note that Stash requires the database to keep idle connections alive for at least 10 minutes. If the database is configured with less than a 10 minute connection timeout, there will be seemingly random connection errors.

Here is an example of how to do that. When Stash and MySQL run on the same physical computer (accessible through localhost), run the following commands (replacing stashuser and password with your own values):

```sql
mysql> CREATE DATABASE stash CHARACTER SET utf8 COLLATE utf8_bin;
mysql> GRANT ALL PRIVILEGES ON stash.* TO 'stashuser'@'localhost' IDENTIFIED BY 'password';
mysql> FLUSH PRIVILEGES;
mysql> QUIT
```

This creates an empty MySQL database with the name stash, and a user that can log in from the host that Stash is running on who has full access to the newly created database. In particular, the user should be allowed to create and drop tables, indexes and other constraints.

If the MySQL database and Stash servers are on the same physical computer, you can use localhost and not set a password by omitting IDENTIFIED BY 'password' from the 2nd MySQL statement above (if you trust the security within this computer).

If the MySQL database and Stash servers are on different computers, just replace the localhost part of the GRANT ALL statement above with the hostname of the machine that Stash is running on. See the documentation at http://dev.mysql.com/doc/refman/5.1/en/account-names.html.

Note that Stash will generally require about 25–30 connections to the database.

Connect Stash to the MySQL database

You can now connect Stash to the MySQL database, either:

- when you run the Setup Wizard, at install time,
- when you wish to migrate to MySQL, either from the embedded database or from another external database.

When running the Setup Wizard at install time

1. Select External at the ‘Database’ step.
2. Select MySQL for Database Type.
3. Complete the form. See the table below for details.
4. Click Next, and follow the instructions in the Stash Setup Wizard.

When migrating to MySQL
1. In the administration area, click **Database** (under 'Settings').
2. Click **Migrate database**.
3. Select **MySQL** for **Database Type**.
4. Complete the form. See the table below for details.
5. Click **Start Migration**.

**Connecting Stash to Oracle**

This page describes how to connect Stash to a Oracle database.

The overall process for using a Oracle database with Stash is:

- Install Oracle where it is accessible to Stash.
- Create a database and user on the Oracle server for Stash to use.
- Install Stash on **Windows**, or on **Linux or Mac**.
- Either:
  - at Stash install time, run the Setup Wizard to connect Stash to the Oracle database, or
  - at a later time, migrate Stash to the Oracle database.

It is assumed here that you already have Oracle installed and running. For information about installing Oracle.
and creating Oracle databases, see the Oracle documentation pages. For the versions of Oracle supported by Stash see Supported platforms.

On this page:
- Prerequisites
- Connect Stash to the Oracle database
- Install the JDBC driver

Backup

If you are migrating your data from the internal Stash database, back up the Stash home directory.

If you are migrating your Stash data from a different external database, back up that database by following the instructions provided by the database vendor before proceeding with these instructions.

See Data recovery and backups.

Create the Oracle schema for Stash

Before you can use Stash with Oracle, you must set up Oracle as follows:

- Ensure that you have a database instance available for Stash (either create a new one or use an existing one)
  The character set of the database must be set to either AL32UTF8 or UTF8, to support storage of Unicode data as per the Oracle documentation.

Note that it is important to the proper operation of Stash that the database store its data in a case-sensitive manner. By changing the values of the NLS_COMP and/or NLS_SORT variables, it is possible to cause Oracle to perform its searches in a case-insensitive manner. We therefore strongly recommend that those variables be left at their default values.

- Create a user that Stash will connect as (e.g. stash).
  ✓ Remember the database user name; it will be used to configure Stash’s connection to the database in subsequent steps.
  🔄 When you create a user in Oracle, a schema is automatically created.
  It is strongly recommended that you create a new database user for use by Stash rather than sharing one that is used by other applications or people.

- Grant the Stash user connect and resource roles only. The connect role is required to set up a connection, while resource role is required to allow the user to create objects in its own schema.

- Create a local all_objects view to the user’s schema, so that there is no possibility that a table with the same name as one of the Stash tables in another schema will cause any conflicts.

- Note that Stash requires the database to keep idle connections alive for at least 10 minutes. If the database is configured with less than a 10 minute connection timeout, there will be seemingly random connection errors.

The format of the command to create a user in Oracle is:

```
CREATE USER <user>
IDENTIFIED BY <password>;
GRANT CONNECT, RESOURCE to <user>;
CREATE VIEW <user>.all_objects AS
SELECT *
FROM sys.all_objects
WHERE owner = upper(''<user>''));
```
Here is a simple example, using SQL*Plus, of how one might create a user called `stash` with password `jdHyd6Sn21` in tablespace `users`, and grant the user a minimal set of privileges. When you run the command on your machine, remember to replace the user name, password and tablespace names with your own values.

```
CREATE USER stash
    IDENTIFIED BY jdHyd6Sn21;

GRANT CONNECT, RESOURCE to stash;
CREATE VIEW stash.all_objects AS
    SELECT *
    FROM sys.all_objects
    WHERE owner = upper('stash');
```

This creates an empty Oracle schema with the name `stash`, and a user that can log in from the host that Stash is running on and who has full access to the newly created schema. In particular, the user is allowed to create sessions and tables.

Note that Stash will generally require about 25–30 connections to the database.

### Connect Stash to the Oracle database

You can now connect Stash to the Oracle database, either:

- when you run the Setup Wizard, at install time,
- when you wish to migrate to Oracle, either from the embedded Stash database or from another external database.

#### When running the Setup Wizard at install time

1. Select **External** at the 'Database' step.
2. Select **Oracle** for **Database Type**.
3. Complete the form. See the table below for details.
4. Click **Next**, and follow the instructions in the Stash Setup Wizard.

#### When migrating to Oracle

1. In the Stash administration area, click **Database** (under 'Settings').
2. Click **Migrate database**.
3. Select **Oracle** for **Database Type**.
4. Complete the form. See the table below for details.
5. Click **Start Migration**.

<table>

<tr>
<td>Port</td>
<td>The TCP port with which Stash can connect to the database server. The default value is the default port that Oracle runs against. You can change that if you know the port that your Oracle instance is using.</td>
</tr>
</tbody>
</table>
### Database name

The system identifier of the Oracle instance that Stash should connect to. Stash does not support connecting to Oracle servers which are using SID or TNS Alias to identify themselves; it requires the fully qualified Service Name instead.

### Database username

The username that Stash should use to access the database.

### Database password

The password that Stash should use to access the database.

#### Install the JDBC driver

This section is only relevant to some distributions of Stash, for example if you are running Stash via the Atlassian Plugin SDK, or have built Stash from source.

If the Oracle JDBC driver is *not* bundled with Stash, you will need to download and install the driver yourself.

1. Download the appropriate JDBC driver from the Oracle [download site](#).
2. Copy the downloaded jar file to your `<Stash home directory>/lib` directory (for Stash 2.1 or later).
3. Stop, then restart, Stash on Windows, or on [Linux and Mac](#).

#### Connecting Stash to PostgreSQL

This page describes how to connect Stash to a PostgreSQL database.

The overall process for using a PostgreSQL database with Stash is:

- Install PostgreSQL where it is accessible to Stash.
- Create a database and user on the PostgreSQL server for Stash to use.
- Install Stash on [Windows](#), or on [Linux or Mac](#).
- Either:
  - at Stash install time, run the Setup Wizard to connect Stash to the PostgreSQL database, or
  - at a later time, migrate Stash to the PostgreSQL database.

It is assumed here that you already have PostgreSQL installed and running. For more information about PostgreSQL installation and operation, refer to the [PostgreSQL documentation](#).
PostgreSQL has the idea of schemas. When you create a PostgreSQL database, a ‘public’ schema is created and set as the default for that database. It is possible to create a different schema (e.g. 'stash') and set that as the default schema. Stash will use whatever schema is set as the default for the logged-in user. Stash does not provide a way for a user to nominate the schema to use; it uses schema that is set as the PostgreSQL default.

See Supported platforms for the versions of PostgreSQL supported by Stash.

Prerequisites

**Backup**

If you are migrating your Stash data from the HSQL internal database, back up the Stash home directory.

If you are migrating your Stash data from another external database, back up that database by following the instructions provided by the database vendor before proceeding with these instructions.

See Data recovery and backups.

**Create the Stash database**

Before you can use Stash with PostgreSQL, you must:

- Create a role for Stash to use when it connects to the database. We strongly recommend that this role be established for Stash's use exclusively; it should not be shared by other applications or people.
- Create a database in which Stash can store its data. The database must be configured to use the UTF-8 character set. During normal operation, Stash will acquire 25–30 connections to the database.
- Note that Stash requires the database to keep idle connections alive for at least 10 minutes. If the database is configured with less than a 10 minute connection timeout, there will be seemingly random connection errors.

Here is an example of how to create a user called *stashuser* with password *jellyfish*, and a database called *stash*, which is configured for use by *stashuser*. Using a PostgreSQL client application like *psql* or *pgAdmin*, run the following commands, replacing the user name, password, and database name with your own values.

```
CREATE ROLE stashuser WITH LOGIN PASSWORD 'jellyfish' VALID UNTIL 'infinity';
CREATE DATABASE stash WITH ENCODING='UTF8' OWNER=stashuser CONNECTION LIMIT=-1;
```

If the server that is hosting the PostgreSQL database is not the same server as Stash, then please ensure that the Stash server can connect to the database server. Please also refer to the PostgreSQL documentation on how to set up *pg_hba.conf*. If the *pg_hba.conf* file is not set properly, remote communication to the PostgreSQL server will fail.

**Connect Stash to the PostgreSQL database**

You can now connect Stash to the PostgreSQL database, either:
• when you run the Setup Wizard, at install time,
• when you wish to migrate Stash to PostgreSQL, either from the embedded HSQL database or from another external database.

When running the Setup Wizard at install time

1. Select External at the 'Database' step.
2. Select PostgreSQL for Database Type.
3. Complete the form. See the table below for details.
4. Click Next, and follow the instructions in the Stash Setup Wizard.

When migrating to PostgreSQL

1. In the Stash administration area, click Database (under "Settings").
2. Click Migrate database.
3. Select PostgreSQL for Database Type.
4. Complete the form. See the table below for details.
5. Click Start Migration.

5. Click **Start Migration**.

<table>
<thead>
<tr>
<th>Hostname</th>
<th>The host name or IP address of the computer running the database server.</th>
</tr>
</thead>
</table>
Port
The TCP port with which Stash can connect to the database server. The default value of 1433 is the default port that SQL Server runs against. You can change that if you know the port that your SQL Server instance is using.

Database name
The name of the database that Stash should connect to.

Database username
The username that Stash should use to access the database.

Database password
The password that Stash should use to access the database.

Use Integrated Authentication or 'Windows Authentication Mode' (Optional)

Windows authentication is only available for Stash instances running on Windows. It cannot be used on Linux because Microsoft does not provide shared objects for it. You will either need to run Stash on Windows, allowing you to use Windows security, or you will need to enable mixed-mode authentication for SQL Server if you are running Stash on Linux. Unfortunately, there are no other options at this time.

Integrated authentication uses a native DLL to access the credentials of the logged-in user to authenticate with SQL Server. The native DLLs for both 32- and 64-bit systems are included in the distribution; there is no need to download the entire package from Microsoft.

Stash does not currently support configuring the system to use integrated authentication from the UI (Vote for it! [+STASH-3035 - Add support for integrated authentication for Microsoft SQL Server | OPEN ]). This means you can't currently migrate to SQL Server with integrated authentication, nor can you configure Stash to use SQL Server with integrated authentication during initial setup. However, if Stash has already been configured to use SQL Server (for example, when the Setup Wizard was run at first use), you can enable integrated authentication by directly modifying Stash's configuration, as follows:

Named Instances
If you have a named instance on your server, you will need to manually edit the stash-config.properties file as described on the Connecting to named instances in SQL Server from Stash Knowledge Base article.
1. Based on the JVM being used to run Stash, rename either the x64 or x86 DLL to sqljdbc_auth.dll in lib/native. Note that running on Windows x64 does not require the use of the x64 DLL; you should only use the x64 DLL if you are also using a 64-bit JVM.

2. In setenv.bat, a JVM_LIBRARY_PATH variable has already been defined. Simply remove the leading `rem`. Note that if you are putting the native DLL in an alternative location, you may need to change the value to point to your own path. The value of the JVM_LIBRARY_PATH variable will automatically be included in the command line when Tomcat is run using start-stash.bat.

3. Edit the `%STASH_HOME%\stash-config.properties` file to include; `integratedSecurity=true` in the `jdbc.url` line. Note that `jdbc.user` and `jdbc.password` will no longer be used to supply credentials but they must still be defined – Stash will fail to start if these properties are removed.

4. Ensure the Stash process or service is running as the correct user to access SQL Server.

   It is also possible to configure integrated authentication over Kerberos, rather than using the native DLLs. Details for that are included in the JDBC documentation.

Install the JDBC driver

This section is only relevant to some distributions of Stash, for example if you are running Stash via the Atlassian Plugin SDK, or have built Stash from source.

If the SQL Server JDBC driver is not bundled with Stash, you will need to download and install the driver yourself.

1. Download the appropriate JDBC driver from the Microsoft download site.
2. Install the driver file to your `<Stash home directory>/lib` directory (for Stash 2.1 or later).
3. Stop, then restart, Stash on Windows, or on Linux and Mac.

If Stash was configured to use Microsoft SQL Server by manually entering a JDBC URL, please refer to this guide.

**Transitioning from jTDS to Microsoft’s JDBC driver**

This page describes how to change from using jTDS to using the Microsoft SQL Server JDBC driver to access Microsoft SQL Server.

What do I have to do?

If Stash was configured to use Microsoft SQL Server by following the steps outlined in Connecting Stash to SQL Server, no change is necessary. However, If Stash was configured to use Microsoft SQL Server by manually entering a JDBC URL, the system will lock on startup if the driver class and URL are not manually updated.

How to proceed

In the Stash home directory, `stash-config.properties` must be edited to change the JDBC driver and URL. The existing configuration should look similar to this:

```
jdbc.driver=net.sourceforge.jtds.jdbc.Driver
jdbc.url=jdbc:jtds:sqlserver://localhost:1433;databaseName=stash;
jdbc.user=stashuser
jdbc.password=secretpassword
```

The JDBC URL above is in the format constructed by Stash when Connecting Stash to SQL Server and will automatically be updated to a URL compatible with Microsoft’s driver, with no change required on the administrator’s part. If the URL contains additional properties, such as domain=, it will need to be manually updated.

To use Microsoft’s SQL Server driver, the settings above would be updated to this:
jdbc.driver=com.microsoft.sqlserver.jdbc.SQLServerDriver
jdbc.url=jdbc:sqlserver://localhost:1433;databaseName=stash;
jdbc.user=stashuser
jdbc.password=secretpassword

The exact values to use in the new URL are beyond the scope of this documentation; they must be chosen based on the jTDS settings they are replacing.

Additional Information for the curious

The new JDBC driver class is: com.microsoft.sqlserver.jdbc.SQLServerDriver

The JDBC URL format for the jTDS driver is documented on SourceForge at http://jtds.sourceforge.net/faq.html#urlFormat.

Why change drivers?

Click here to find all the technical details...

Recent releases of Hibernate, which Stash uses to simplify its persistence layer, have introduced a requirement that the JDBC drivers and connection pools used be JDBC4-compliant. JDBC4 was introduced with Java 6.

The jTDS driver used by releases prior to Stash 2.1 is a JDBC3 driver, compatible with Java 1.3, and therefore cannot be used with newer versions of Hibernate. While jTDS 1.3.0 implements JDBC4, and JDBC4.1 which is provided by Java 7, it requires a Java 7 runtime environment. Upgrading Stash to that version was a non-starter, as it would require raising the minimum Java version for the product to Java 7.

Instead, the decision was made to replace jTDS with Microsoft's own SQL Server driver. Microsoft's driver is actively maintained, where jTDS is only recently seeing its first updates in over 3 years, and supports all the features of SQL Server, including SQL Server 2012.

Stash attempts to automatically update jTDS JDBC URLs to values compatible with Microsoft's JDBC driver. However, for installations using custom JDBC URLs—for example, to use domain authentication—such automatic updating is not possible; the URL, which was manually entered, must be manually updated.

Migrating Stash to another server

This page describes how to move your Stash installation from one physical machine to a different machine. For most scenarios, the overall procedure involves the following 3 steps, although your situation may not require all of these:

1. Move the Stash data.
2. Move the Stash installation to the new location, and update STASH_HOME.
3. Update the Stash stash-config.properties file. This will be necessary if you were unable to use the Migration Wizard in Step 1.

See also the Stash upgrade guide. You can upgrade Stash either before or after you migrate Stash. This page does not describe any aspect of the upgrade procedure.

On this page:

First steps
1. Move the Stash data to a different machine
2. Move Stash to a different machine
3. Update the Stash configuration
First steps

In preparation for migrating Stash to another server, check that you have done the following:

- Confirm that the operating system, database, other applicable platforms and hardware on the new machine will comply with the requirements for Stash.
- Check for any known migration issues in the Stash Knowledge Base.
- Alert users to the forthcoming Stash service outage.
- Ensure that users will not be able to update existing Stash data during the migration. You can do this by temporarily changing the access permissions for Stash.
- Make sure you have created a user in Stash (not in your external user directory) that has System Administrator global permissions so as to avoid being locked out of Stash in case the new server does not have access to your external user directory.

1. Move the Stash data to a different machine

This section gives a brief overview of how to move the Stash data to a different machine. You do not need to do anything in this section if you will continue to use the embedded database - the Stash data is moved when you move the Stash installation.

The Stash data includes the data directories (including the Git repositories), log files, installed plugins, temporary files and caches.

You can move the Stash data:

- from the embedded database to a supported external DBMS.
- to another instance of the same DBMS.
- from one DBMS to another supported DBMS (for example, from MySQL to PostgreSQL).

You can also move the actual DBMS. Atlassian recommends that for large installations, Stash and the DBMS run on separate machines.

There are 2 steps:

1. Create and configure the DBMS in the new location. Please refer to Connecting Stash to an external database, and the relevant child page, for more information.
2. Either:
   - If the new location is currently visible to Stash, use the Stash Database Migration Wizard. Please refer to Connecting Stash to an external database, and the relevant child page, for more information.
   - If the new location is not currently visible to Stash (perhaps because you are moving to a new hosting provider), you need to perform a database export and then import the backup to the new DBMS. Please refer to the vendor documentation for your DBMS for detailed information. You will also need to update the stash-config.properties file in the <Stash home directory> as described below.

2. Move Stash to a different machine

This section describes moving the Stash installation to a different machine.

1. Stop Stash. Use bin\stop-stash.bat on Windows, or bin/stop-stash.sh on Linux and Mac.
2. Make an archive (such as a zip file) of the Stash home directory. The home directory contains data directories (including the Git repositories), log files, installed plugins, temporary files and caches. The home directory location is defined:
   - on Windows, by the STASH_HOME environment variable, or by the STASH_HOME line of <Stash
3. Copy the archive to the new machine and unzip it to its new location there.
4. Set up an instance of Stash in the new location by doing one of the following:
   - Make an archive of the old Stash installation directory and copy it across to the new machine.
   - Install the same version of Stash from scratch on the new machine.
5. Redefine the value for STASH_HOME, mentioned in Step 2. above, in the new Stash installation directory, using the new location for your copied home directory. See either Installing Stash on Windows or Installing Stash on Linux and Mac for more information.
6. If you are continuing to use the Stash embedded database, or you used the Migration Wizard to move the Stash data, you should now be able to start Stash on the new machine and have all your data available. Use bin\start-stash.bat on Windows, or bin/start-stash.sh on Linux and Mac. Once you have confirmed that the new installation of Stash is working correctly, revert the access permissions for Stash to their original values.
7. If you moved the Stash data by performing a database export and import, carry on to Step 3. below to update the stash-config.properties file in the Stash home directory.

3. Update the Stash configuration

If you moved the Stash data by performing a database export, you must update the stash-config.properties file in the Stash home directory with the changed configuration parameters for the database connection.

The configuration parameters are described in Stash config properties.

Once the configuration parameters are updated, you should be able to start Stash on the new machine and have all your data available. Use bin\start-stash.bat on Windows, or bin/start-stash.sh on Linux and Mac. Once you have confirmed that the new installation of Stash is working correctly, revert the access permissions for Stash to their original values.

**Specifying the base URL for Stash**

This is the base URL for this installation of Stash. All links which are not from a web request (for example in Stash email notifications), will be prefixed by this URL. If you are experiencing trouble with setting an https base URL, please ensure you have configured Tomcat with SSL correctly.

To specify Stash’s base URL:

1. In the Stash administration area, click Server settings (under ‘Settings’).
2. In the Base URL field, type the URL address of your Stash server (for example, "https://stash.mycompany.com").
3. Click Save.

**Configuring the application navigator**

The application navigator, on the left of the Stash header, allows you to switch to your other applications, such as Atlassian JIRA and Bamboo – or any other web application – all from the Stash header:
Users only see the application navigator when links are set up – if there are no links, only administrators can see it.

Stash administrators can configure which apps appear in the navigator – just click Configure in the application navigator, or go to the Stash admin area and click Application navigator:

- **Linked applications** are automatically configured in the application navigator, and can't be deleted. Click Manage to configure those in the source application.
- Specify new links, as required by your users, by entering a Name and URL.
- Restrict the visibility of links to particular user groups, or hide the link completely. Click in a row, under the Groups column header, to edit those properties for existing rows.
- Use the 'handles' at the left to change the link order when seen in Stash.

### Managing add-ons

An add-on is an installable component that supplements or enhances the functionality of Stash in some way. For example, the Custom Navigation Plugin enables you to configure custom navigation tabs specific to a repository. Other add-ons are available for adding graphs to Stash, importing SVN source control projects into Stash, and accessing Atlassian support from Stash.

Stash comes with many pre-installed add-ons (called system add-ons). You can install more add-ons, either by acquiring the add-on from the Atlassian Marketplace or by uploading it from your file system. This means that you can install add-ons that you have developed yourself. For information about developing your own add-ons for Stash, see the Stash Developer Documentation.

### About the Universal Plugin Manager (UPM)

You administer add-ons for Stash using the Universal Plugin Manager (UPM). The UPM is itself an add-on that exposes add-on administration pages in the Stash Administration Console. UPM works across Atlassian applications, providing a consistent interface for administering add-ons in Stash, Crucible, Confluence, Fisheye, JIRA and Bamboo.
UPM comes pre-installed in recent versions of all Atlassian applications, so you do not normally need to install it yourself. However, like other add-ons, the UPM software is subject to regular software updates. Before administering add-ons in Stash, therefore, you should verify your version of the UPM and update it if needed.

### Administering add-ons in Stash

You can update UPM, or any add-on, from the UPM's own add-on administration pages. Additionally, you can perform these tasks from the UPM administration pages:

- Install or remove add-ons
- Configure add-on settings
- Discover and install new add-ons from the Atlassian Marketplace
- Enable or disable add-ons and their component modules

It shows only those plugins that are supported in your version of the product, so that you do not install incompatible plugins.

If the add-on request feature is enabled in your Atlassian application, non-administrative users can also discover add-ons on the Atlassian Marketplace. Instead of installing the add-ons, however, these users have the option of requesting the add-ons from you, the administrator of the Atlassian application.

For more information on administering the add-on request feature or performing other common add-on administration tasks, see the Universal Plugin Manager documentation. For an end-user's view of requesting add-ons in Stash, see Requesting add-ons.

### POST service webhook for Stash

Repository administrators can add a POST service to a repository. Stash POSTs to the service URL you specify.

You can use an URL with the following format:

```
https://server:port/path/
```

The service receives a POST whenever the user pushes to the repository.

The content type header of the POST has an application/json type. The content is a JSON payload that represents the repository push.

### Setting up the POST service

You can either set up the POST service manually or you can write a service to automate this. You would write a service if you are integrating an application with Stash.

Manually from Repository Administration

1. Go to the repository's settings.
2. Click **Hooks** in the left-hand navigation.
3. Select the **Post-Receive Webhooks** item from the listing.
4. Click **Enable**. A new dialog appears for the **POST** hook. You can add up to 5 hooks:
5. Enter the URL where Stash should send its update messages.
6. Press Enable.

POST data

When a user pushes to a repository, Stash POSTs to the URL you provided. The body of the POST request contains information about the repository where the change originated, a list of recent commits, and the user that made the push.

Example of payload

This is an example of a push that contains one commit that changes 2 files (`pom.xml`) in folders `iridium-common` and `iridium-magma`.

Audit logging in Stash

Stash comes with an internal audit system enabled by default at installation. The audit system is intended to give administrators an insight into the way Stash is being used. The audit system could be used to identify authorized and unauthorized changes, or suspicious activity over a period of time.

Viewing recent events

Stash administrators and system administrators can see a list of recent events for each project and repository in the ‘Audit log’ view. This is found under the Settings tab for a project or repository, and shows only the most important audit events.
The audit log displays a subset of the events recorded in the log file and is kept to a configurable maximum size (the default is 500 events). See Audit events in Stash for more details.

Accessing the audit log file

The full audit log file records a wide range of events in Stash. See Audit events in Stash for a list of these. The volume of events that are logged is coarsely configurable by changing a Stash server setting. See Stash config properties for more details.

You can find the log file in the `<Stash home directory>/log/audit` directory.

The log file will roll daily and also when it grows past a maximum size of 25 MB. There is a limit (currently 100) to the number of rolled files that Stash will keep. When the limit is reached, the oldest file is deleted each day.

Note that you will need to back up the log files before they are removed, if your organisation needs to keep copies of those.

Configuring audit logging

There are various system properties that can be used to configure audit logging in Stash.

Audit events in Stash

The auditing component of Stash will log many different events that occur when Stash is being used. The events have been assigned priorities based on how important they are – these priorities can be used to control how much information is added to the audit log file. For example, if you have a server under high load and no need for auditing, you may wish to turn audit logging off by setting it to `NONE` – see the audit log config properties.

**Scaling Stash**

**Hardware requirements**
The type of hardware you require to run Stash depends on a number of factors:

- The number and frequency of clone operations. Cloning a repository is one of the most demanding operations. One major source of clone operations is continuous integration. When your CI builds involve multiple parallel stages, Stash will be asked to perform multiple clones concurrently, putting significant load on your system.
- The size of your repositories – there are many operations in Stash that require more memory and more CPUs when working with very large repositories. Furthermore, huge Git repositories (larger than a few
GBs) are likely to impact the performance of the Git client – see this discussion.

- The number of users.

The following are rough guidelines for choosing your hardware:

- Estimate the number of concurrent clones that are expected to happen regularly (look at continuous integration). Add one CPU for every 2 concurrent clone operations. Note that enabling the SCM Cache Plugin (bundled with Stash from version 2.5.0) can help to reduce the cloning load on the Stash server due to CI polling. See Scaling Stash for Continuous Integration performance.
- Estimate or calculate the average repository size and allocate 1.5 x number of concurrent clone operations x min(repository size, 700MB) of memory.

Understanding Stash's resource usage

Most of the things you do in Stash involve both the Stash server and one or more Git processes created by Stash. For instance, when you view a file in the Stash web application, Stash processes the incoming request, performs permission checks, creates a Git process to retrieve the file contents and formats the resulting webpage. In serving most pages, both the Stash server and Git processes are involved. The same is true for the 'hosting' operations: pushing your commits to Stash, cloning a repository from Stash or fetching the latest changes from Stash.

As a result, when configuring Stash for performance, CPU and memory consumption for both Stash and Git should be taken into account.
Memory

When deciding on how much memory to allocate for Stash, the most important factor to consider is the amount of memory required for Git. Some Git operations are fairly expensive in terms of memory consumption, most notably the initial push of a large repository to Stash and cloning large repositories from Stash. For large repositories, it is not uncommon for Git to use up to 500 MB of memory during the clone process. The numbers vary from repository to repository, but as a rule of thumb 1.5 x the repository size on disk (contents of the .git/objects directory) is a rough estimate of the required memory for a single clone operation for repositories up to 400 MB. For larger repositories, memory usage flattens out at about 700 MB.

The clone operation is the most memory intensive Git operation. Most other Git operations, such as viewing file history, file contents and commit lists are lightweight by comparison.

Stash has been designed to have fairly constant memory usage. Any pages that could show large amounts of data (e.g. viewing the source of a multi-megabyte file) perform incremental loading or have hard limits in place to prevent Stash from holding on to large amounts of memory at any time. In general, the default memory settings (max. 768 MB) should be sufficient to run Stash. The maximum amount of memory available to Stash can be configured in setenv.sh or setenv.bat.

CPU

In Stash, much of the heavy lifting is delegated to Git. As a result, when deciding on the required hardware to run Stash, the CPU usage of the Git processes is the most important factor to consider. And, as is the case for memory usage, cloning large repositories is the most CPU intensive Git operation. When you clone a repository, Git on the server side will create a pack file (a compressed file containing all the commits and file versions in the repository) that is sent to the client. While preparing a pack file, CPU usage will go up to 100% for one CPU.

For users that connect to Stash using SSH, the encryption of data adds to overall CPU usage. For day-to-day push and pull operations the overhead will not be significant, but when cloning repositories the overhead will be noticeable.

To get the maximum performance from Stash, we advise configuring automatic build tools to use the http or https protocol, if possible.

Clones examined

Since cloning a repository is the most demanding operation in terms of CPU and memory, it is worthwhile analyzing the clone operation a bit closer. The following graphs show the CPU and memory usage of a clone of a 220 MB repository:

**Git process (blue line)**
- CPU usage goes up to 100% while the pack file is created on the server side.
- CPU peaks at 120% when the pack file is compressed (multiple CPUs used).
- CPU drops back to 0.5% while the pack file is sent back to the client.

**Stash (red line)**
- CPU usage briefly peaks at 30% while the clone request is processed.
- CPU drops back to 0% while Git prepares the pack file.
- CPU hovers around 1% while the pack file is sent to the client.
Configuring Stash scaling options and system properties

Stash limits the number of Git operations that can be executed concurrently, to prevent the performance for all clients dropping below acceptable levels. These limits can be adjusted – see Stash config properties.

Database requirements

The size of the database required for Stash depends in large part on the number of repositories and the number of commits in those repositories.

A very rough guideline is: $100 + \left(\frac{\text{total number of commits across all repos}}{2500}\right) \text{ MB}.$

So, for example, for 20 repositories with an average of 25,000 commits each, the database would need $100 + \left(\frac{20 \times 25,000}{2500}\right) = 300\text{MB}.$

Scaling Stash for Continuous Integration performance

If you’ve got CI or other automatic tooling set up to poll Stash for changes, you can end up with high load on your Stash server. Consider for instance a CI server that has a number of builds set up for a given repository. Each of those builds polls Stash for changes and when it detects a change, it starts a new build. If your CI server supports parallel and/or chained build steps, each of these builds typically results in multiple clone operations of the same repository. The result: lots of polling for changes, and bursts of clones of a repository.

Caching

CI results in highly repetitive calls to Stash: polling for changes typically results in the same response 90% of the time and a build triggers a number of identical clone calls to Stash. Both operations can benefit greatly from caching when you experience repetitive load from CI.

Stash 2.5, and later versions, ship with the SCM Cache plugin already bundled. The plugin is enabled by default, but note that ref advertisement is disabled by default – see the 'Limitations' section below. The plugin is also available from the Atlassian Marketplace.
Limitations

- Caching can be applied to 'ref advertisement' (polling for changes), clone and shallow clone requests only. Fetch/pull operations are not cached, but these operations will still benefit from the 'ref advertisement' cache.
- As a precaution, ref advertisement caching is disabled by default. The openness of the plugin system means that plugins (or manually installed git hooks) could be updating refs in repository without the caching plugin detecting these changes. The result would be a stale refs cache and failing clone/fetch operations. However, if you know that there are no plugins or git hooks installed that make changes to the repository directly, you can enable the ref advertisement caching using the system properties listed in the Configuration section below. Note that as an additional precaution, the ref advertisement caches are configured to automatically expire after a minute.

Enabling and disabling caching

Enable the SCM Cache Plugin from the admin area in Stash. Click Manage Add-ons (under 'Add-Ons') and filter for system add-ons. Click SCM Cache Plugin for Stash and then either Enable or Disable.

Configuration

The SCM Cache Plugin for Stash can be configured using either the REST endpoint (some settings, not all) or the system properties in `<STASH-HOME>/stash-config.properties`. Settings configured through REST are considered before the settings in stash-config.properties. See Stash config properties for descriptions of the available system properties.

### Stash production server data

This page provides some data around the Stash production instance that we run internally at Atlassian. We're providing this to give some idea of how Stash performs in a production environment. Please realise that this information is entirely specific to this particular instance – the details of your own installation may result in different performance data.

This data was collected with New Relic in February 2013, when the server was running a pre-release version of Stash 2.2.

Debug logging for the Stash server

This section describes how to enable debug level logging in Stash. Stash logs can be found in `<STASH_HOME>/log`.

When using the standard Stash distribution, logs for the Tomcat webserver that hosts Stash can be found in `<Stash installation directory>/log`.

**Enabling debug logging via the UI**

To enable debug logging, go to the Stash admin area, choose **Logging and Profiling** (under ‘Support’) and select **Enable debug logging**.

**Enabling debug logging on startup**

To enable debug logging whenever Stash is started, edit the `<STASH_HOME>/stash-config.properties` file (if this file doesn’t exist then you should create it) and add the following two lines:

```properties
logging.logger.ROOT=DEBUG
logging.logger.com.atlassian.stash=DEBUG
```

**Enabling debug logging at runtime**

To enable debug logging for the root logger once Stash has been started, run the following two commands in your terminal:
To enable debug logging for a specific logger, run the following command in your terminal:

```bash
curl -u <ADMIN_USERNAME> -v -X PUT -d "" -H "Content-Type: application/json" <BASE_URL>/rest/api/latest/logs/logger/<LOGGER_NAME>/debug

# e.g.
curl -u admin -v -X PUT -d "" -H "Content-Type: application/json"
```

### Profiling logging for the Stash server

This section describes how to enable profiling in Stash. This log is essential when troubleshooting performance issues. Stash logs can be found in `<STASH_HOME>/log`.

When using the standard Stash distribution, logs for the Tomcat webserver that hosts Stash can be found in `<Stash installation directory>/log`.

#### Enabling profiling logging via the UI

To turn on detailed trace information, go to the Stash admin area, choose **Logging and Profiling** (under 'Support') and select **Enable profiling**.

### Debug logging for Git operations on the client

Atlassian Support might request DEBUG logs for Git operations (on the client) when troubleshooting issues. You can enable DEBUG logging on the Git client by setting the following variables.

**On Linux**

Execute the following in the command line before executing the Git command:

```bash
export GIT_TRACE_PACKET=1
export GIT_TRACE=1
export GIT_CURL_VERBOSE=1
```

**On Windows**

Execute the following in the command line before executing the Git command:

```bash
set GIT_TRACE_PACKET=1
set GIT_TRACE=1
set GIT_CURL_VERBOSE=1
```
Debug logging for the Stash Backup Client

Atlassian Support might request DEBUG logs for the Backup client when troubleshooting issues.

You can enable DEBUG logging on the Backup client by adding a file named logback.xml to the directory where you run the backup client with the following content:

```
<included>
<logger name="com.atlassian.stash" level="DEBUG"/>
</included>
```

Stash config properties

This page describes Stash system properties that can be used to control aspects of the behaviour in Stash. System properties are contained in the stash-config.properties file, in your Stash home directory.

Stash must be restarted for changes to become effective.

Default values for system values, where applicable, are specified in the tables below.

Audit

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>

Created in 2014 by Atlassian. Licensed under a Creative Commons Attribution 2.5 Australia License.
audit.highest.priority.to.log=HIGH

Defines the lowest priority audit events that will be logged. Accepted values are: HIGH, MEDIUM, LOW and NONE.

Setting the value to HIGH will result in only HIGH level events being logged. NONE will cause no events to be logged. MEDIUM will only allow events with a priority of MEDIUM and HIGH to be logged.

Refer to the levels for the various events.

This does not affect events displayed in the Audit log screens for projects and repositories.

audit.details.max.length=1024

Defines the number of characters that can be can stored as details for a single audit entry.

plugin.stash-audit.max.entity.rows=500

The maximum number of entries a project or repository can have in the audit tables.

This does not affect the data stored in the logs.

plugin.stash-audit.cleanup.batch.size=1000

When trimming the audit entries table this is the maximum number of rows that will be trimmed in one transaction. Reduce this size if you are having issues with long running transactions.

This does not affect the data stored in the logs.

plugin.stash-audit.cleanup.run.interval=24

How often the audit tables will be checked to see if they need to be trimmed (in hours).

This does not affect the data stored in the logs.

Authentication

<table>

Database

Database properties allow very specific configuration for your database connection parameters, which are set by Stash during database setup and migration, and allow you to configure a database of your own. We don't expect that you will edit these, except in collaboration with Atlassian Support.

Any other driver must be placed in WEB-INF/lib in order to use the associated database.

⚠️ Warning: jdbc.driver and jdbc.url are available to plugins via the ApplicationPropertiesService. Some JDBC drivers allow the username and password to be defined in the URL. Because that property is available throughout the system (and will be included in STP support requests), that approach should not be used. The jdbc.username and jdbc.password properties should be used for these values instead.

If none of the values below are specified in stash-config.properties, then a provided HSQL database will be used.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
jdbc.driver=org.hsqldb.jdbcDriver

The JDBC driver class that should be used by Stash to connect to the database. The default Stash database uses the file-based HSQL database (org.hsqldb.jdbcDriver), storing its data in the <stash home directory>. Stash currently bundles these other JDBC drivers:

- org.postgresql.Driver (more info)
- com.microsoft.sqlserver.jdbc.SQLServerDriver (more info)
- oracle.jdbc.driver.OracleDriver (more info)

⚠️ The JDBC drivers for MySQL are not bundled with Stash (due to licensing restrictions) so you will need to download and install the driver yourself. See this page for directions on installing the driver: Connecting Stash to MySQL

jdbc.url=jdbc:hsqldb:${stash.home}/data/db;shutdown=true

This is the JDBC url that Stash will use to connect to the database. This should include the driver subprotocol (e.g., postgresql://), the hostname, port and database that you will connect to. This string may vary depending on the database you are connecting to. Please seek specific examples for other databases from your database provider.

jdbc.user=SA

This is the user that Stash will connect to the database with. The user will need to be able to create and drop tables and indexes, as well as read and write operations on the entire database schema defined in jdbc.url.

jdbc.password=

The password that the user defined by jdbc.user will connect with.

jdbc.ignoreunsupported=false

Allows using a given database, even though it is marked as UNSUPPORTED. This is not intended to be broadly documented, nor to be used generally. It is here as a support mechanism to override the supported database check in the event that it incorrectly blocks access to a database.

### Database pool

These properties control the database pool. The pool implementation used is BoneCP. Documentation for these settings can be found at: [http://jolbox.com/configuration.html](http://jolbox.com/configuration.html)

To get a feel for how these settings really work in practice, the most relevant classes in BoneCP are:

- com.jolbox.bonecp.BoneCP - Creates the partitions, opens initial connections, starts threads
- com.jolbox.bonecp.BoneCPDataSource - Manages the pool, bridge to the DataSource interface
- com.jolbox.bonecp.PoolWatchThread - Handles the connection threshold

<table>
<thead>
<tr>

<td>Description</td>
</tr>
<tr>
<td>---------------</td>

</tr>
<tr>
<td>db.pool.cache.statements=100</td>
<td>Defines the number of statements to cache. If you configure your JDBC driver to use loadbalancing or failover with the Stash server, you may need to set <code>db.pool.cache.statements=0</code>. Please note that Stash does not yet (as of version 2.8) support DB redundancy, and that this configuration change is not supported by Atlassian.</td>
</tr>
<tr>
<td>db.pool.connection.timeout=15</td>
<td>Defines the amount of time the system will wait when attempting to open a new connection before throwing an exception. The system may hang, during startup, for the configured number of seconds if the database is unavailable. As a result, the timeout configured here should <strong>not</strong> be generous. Value is in SECONDS.</td>
</tr>
<tr>
<td>db.pool.idle.maxAge=30</td>
<td>Defines the maximum period of time a connection may be idle before it is closed. Generous values should be used here to prevent creating and destroying many short-lived database connections (which defeats the purpose of pooling). Value is in MINUTES.</td>
</tr>
<tr>
<td>db.pool.idle.testInterval=10</td>
<td>Defines the amount of time a connection may be idle before a test query is executed by the pool. This helps prevent connections from being closed by the database server due to inactivity. Value is in MINUTES.</td>
</tr>
<tr>
<td>db.pool.partition.connection.maximum=20</td>
<td>Defines the maximum number of connections that may be open in a given partition.</td>
</tr>
<tr>
<td>db.pool.partition.connection.minimum=4</td>
<td>Defines the minimum number of connections open for a given partition. Each partition will open this many connections on startup. That means <code>db.pool.partition.connection.minimum x db.pool.partition.count = initial connection count</code>.</td>
</tr>
<tr>
<td>db.pool.partition.connection.threshold=10</td>
<td>Defines the threshold <em>as a percentage of the maximum connections</em> that each partition will attempt to keep available at all times. If the number of available connections drops <strong>to or below</strong> the threshold, <code>acquireIncrement</code> connections will be opened until the partition is above it again.</td>
</tr>
</tbody>
</table>

⚠️ **Warning:** Be careful to take this number into account when setting the minimum and maximum counts. For example, if the maximum is 30 and the minimum is 5 and the threshold is 20 (20%), 5 is not 20% of 30, so immediately after it is created the partition will open additional connections to get above the threshold. Effectively, that would mean that the "minimum" per partition is 10 (5 + 5 `acquireIncrement`), or 40 connections at all times. |
**db.pool.partition.count=4**

Defines the number of different connection partitions to use. This value is used to decrease lock contention, because each partition locks individually. The recommended setting is 3 or 4, but in servers with heavy load and many short-lived requests, performance may be improved by using a higher value.

**db.pool.threads=4**

Defines the number of helper threads which will be used by the pool to cleanup and release connections back into the pool. Setting a value of 0 disables this feature, which means the executing thread will perform cleanup and release itself. A non-zero value results in a pool of helpers which process connections out of a holding queue. When a thread "closes" a connection, that thread is allowed to continue executing and the connection is placed in the queue. One of the helper threads then performs final cleanup to prepare the connection to be returned to the pool.

### Events

These properties control the number of threads that are used for dispatching asynchronous events. Setting this number too high can decrease overall throughput when the system is under high load because of the additional overhead of context switching. Configuring too few threads for event dispatching can lead to events being queued up, thereby reducing throughput. These defaults scale the number of dispatcher threads with the number of available cpu cores.

<table>

</tr>
<tr>

</tbody>

### Executor

Controls the thread pool that is made available to plugins for asynchronous processing.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>executor.max.threads=100</td>
<td>Specifies the maximum number of threads in the thread pool. When more threads are required than the configured maximum, the thread attempting to schedule an asynchronous task to be executed will block until a thread in the pool becomes available.</td>
</tr>
<tr>
<td>executor.keepAliveTime=60</td>
<td>Controls how long idle threads are kept alive. Threads idle for more than this time will be terminated. Value is in SECONDS and must be &gt;= 1. If 0 or a negative value is used, a default value of 1 will be configured.</td>
</tr>
</tbody>
</table>

### Features

Feature properties control high-level system features, allowing them to be disabled for the entire instance. Features that are disabled at this level are disabled completely. This means that instance-level configuration for a feature is overridden. It also means that a user’s permissions are irrelevant; a feature is still disabled even if the user has the SYS_ADMIN permission.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
feature.auth.captcha=true

Controls whether to require CAPTCHA verification when the number of failed logins is exceeded. If enabled, any client who has exceeded the number of failed logins allowed using either the Stash web interface or the Git hosting interface will be required to authenticate in the Stash web interface and successfully submit a CAPTCHA before continuing. Setting this to false will remove this restriction and allow users to incorrectly authenticate as many times as they like without penalty.

⚠️ Warning: It is STRONGLY recommended you keep this setting enabled. Disabling it will have the following ramifications:

- Your users may lock themselves out of any underlying user directory service (LDAP, Active Directory etc) because Stash will pass through all authentication requests (regardless of the number of previous failures) to the underlying directory service.
- For Stash installations where you use Stash for user management or where you use a directory service with no limit on the number of failed logins before locking out users, you will open Stash or the directory service up to brute-force password attacks.

feature.forks=true

Controls whether repositories can be forked. This setting supersedes and overrides instance-level configuration. If this is set to false, even repositories which are marked as forkable cannot be forked.

feature.public.access=true

Public access to Stash allows unauthenticated users to be granted access to projects and repositories for specific read operations including cloning and browsing repositories. This is normally controlled by project and repository administrators but can be switched off system wide by setting this property to false. This can be useful in highly sensitive environments.

Hibernate

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hibernate.format_sql=false</td>
<td>When hibernate.show_sql is enabled, this flag controls whether Hibernate will format the output SQL to make it easier to read.</td>
</tr>
<tr>
<td>hibernate.jdbc.batch_size=20</td>
<td>Controls Hibernate's JDBC batching limit, which is used to make bulk processing more efficient (both for processing and for memory usage).</td>
</tr>
</tbody>
</table>
hibernate.show_sql=false

Used to enable Hibernate SQL logging, which may be useful in debugging database issues. This value should generally only be set by developers, not by customers.

JIRA

<table>
<thead>
<tr>
<th>Property</th>

Logging

Logging levels for any number of loggers can be set in the stash-config.properties file using the following
format:

```plaintext
logging.logger.<name>=<level>
```

For example, to configure all classes in the com.atlassian.stash package to DEBUG level:

```plaintext
logging.logger.com.atlassian.stash=DEBUG
```

To adjust the ROOT logger, you use the special name ROOT (case-sensitive):

```plaintext
logging.logger.ROOT=INFO
```

Paging

These properties control the maximum number of objects which may be returned on a page, regardless of how many were actually requested by the user. For example, if a user requests Integer.MAX_INT branches on a page, their request will be limited to the value set for `page.max.branches`.

This is intended as a safeguard to prevent enormous requests from tying up the server for extended periods of time and then generating responses whose payload is prohibitively large. The defaults configured here represent a sane baseline, but may be overridden by customers if necessary.

**Process execution**
### Property | Description
--- | ---
`process.timeout.execution=120`<br>`process.timeout.idle=60` | Controls timeouts for external processes, such as Git and Hg. The idle timeout configures how long the command is allowed to run without producing any output. The execution timeout configures a hard upper limit on how long the command is allowed to run even if it is producing output.
Values are in SECONDS. Using 0, or a negative value, disables the timeout completely.

### Pull requests

#### Property | Description
--- | ---
`plugin.stash-scm-git.pullrequest.merge.strategy.KEY.slug=no-ff` | Control the merge strategy for a repository (where KEY is the project key and slug is the repository slug). Note that the URL for the browse page of a repository is of the following form: http://<stashdomain>/projects/<PROJECTKEY>/repos/<reposlug>/browse
Overrides project and global settings.
Possible values are:
- **no-ff** – no fast-forward; the default setting.
- **ff** – allow fast-forward; will merge when necessary.
- **ff-only** – require fast-forward; will never create merge commits; fail if a merge is required.
- **squash** – collapse all incoming commits into a single commit directly to the target branch; never create a merge.
- **squash-ff-only** – collapse all the incoming commits into a single commit directly to the target branch, never creating a merge, but do so only if the source branch is fast-forward.

`plugin.stash-scm-git.pullrequest.merge.strategy.KEY=no-ff` | Control the merge strategy for a project (where KEY is the project key).
Overrides global settings. Is overridden by repository settings.
Possible values are listed above.

`plugin.stash-scm-git.pullrequest.merge.strategy=no-ff` | Control the merge strategy globally. Is overridden by repository and project settings.
Possible values are listed above.

`pullrequest.diff.context=10` | Defines the number of context lines to include around diff segments in pull request diffs. By default, Git only includes 3 lines. The default is 10, to try and include a bit more useful context around changes, until the ability to “expand” the context is implemented.

</tr>
<tr>

<td>Defines the maximum number of threads to use for precalculating rescope details. These threads perform the requisite processing to determine the commits added and removed when a pull request is rescoped, where most rescopes do not add or remove any commits. Such &quot;dead&quot; rescopes are deleted during processing. The primary goal is to ensure all details have already been calculated when users try to view a pull request's overview.</td>
</tr>
<tr>
<td>pullrequest.rescope.drift.threads=4</td>
<td>Defines the maximum number of threads to use when processing comment drift for a pull request during rescope. Higher numbers here do not necessarily mean higher throughput! Performing comment drift will usually force a new merge to be created, which can be very I/O intensive. Having a substantial number of merges running at the same time can significantly reduce the speed of performing comment drift.</td>

**Resource throttling**
These properties define concurrent task limits for the ThrottleService, limiting the number of concurrent Git operations of a given type that may be run at once. This is intended to help prevent Stash from overwhelming a server machine with running processes. Stash has two settings to control the number of Git processes that are allowed to process in parallel: one for the web UI and one for the ‘hosting’ operations (pushing and pulling commits, and cloning a repository).

When the limit is reached for the given resource, the request will wait until a currently running request has completed. If no request completes within a configurable timeout, the request will be rejected.

When requests while accessing the Stash UI are rejected, users will see either a 501 error page indicating the server is under load, or a popup indicating part of the current page failed.

When Git client ‘hosting’ commands (pull/push/clone) are rejected, Stash does a number of things:

- Stash will return an error message to the client which the user will see on the command line: “Stash is currently under heavy load and is not able to service your request. Please wait briefly and try your request again”
- A warning message will be logged for every time a request is rejected due to the resource limits.
- For five minutes after a request is rejected, Stash will display a red banner in the UI to warn that the server is under load.

The hard, machine-level limits these are intended to prevent hitting are very OS- and hardware-dependent, so you may need to tune them for your instance of Stash. When hyperthreading is enabled for the server CPU, for example, it is likely that the server will allow sufficient concurrent Git operations to completely bury the I/O on the machine. In such cases, we recommend starting off with a less aggressive default on multi-cored machines — the value can be increased later if hosting operations begin to back up. These defaults are finger-in-the-wind guesstimates (which so far have worked well).

Additional resource types may be configured by defining a key with the format `throttle.resource.<resource-name>`.

When adding new types, it is strongly recommended to configure their ticket counts explicitly using this approach.

### throttle.resource.scm-hosting.timeout=300

Controls how long threads will wait for SCM hosting operations to complete when the system is already running the maximum number of SCM hosting operations.

Value is in SECONDS.

### throttle.resource.busy.message.timeout=5

Controls how long a warning banner is displayed in the UI after a request is rejected due to excessive load.

Value is in MINUTES. Using 0, or a negative value, disables displaying the banner.

This is deprecated and replaced by `server.busy.on.ticket.rejected.within`, It is due to be removed in Stash 3.0.

Value is in SECONDS.

mail.threads=1

Controls the number of threads to use for sending emails. Setting this to a higher value will put greater load on your mail server when Stash generates a lot of emails, but will make Stash clear its internal queue faster.

mail.max.message.size=1048576

Controls the maximum allowed size of a single mail message, which is the sum of the subject and body sizes.

Value is in BYTES.

mail.max.queue.size=157286400

Controls the maximum allowed size for the mail queue (any new message will be rejected if the mail queue reaches that size).

Value is in BYTES.

**Enabling SSH access to Git repositories in Stash**

A Stash administrator can enable SSH access to Git repositories in Stash. This allows your Stash users to:
• add their own SSH keys to Stash
• use those SSH keys to secure Git operations between their computer and the Stash server.

Stash users must each add their own SSH key pairs to their Stash account to be able to use SSH access to repositories.

Supported key types are DSA and RSA2. Note that RSA1 is not supported. We've tested key sizes of 768, 1024, 2048, 4096 and 8192 bytes.

On this page:
- Enabling SSH access
- SSH base URL
- When running Stash behind a proxy

Performance
There are performance implications for Stash when using SSH. When users connect to Stash using SSH, the encryption of data adds to overall CPU usage. For day-to-day push and pull operations the overhead will not be significant, but when cloning repositories the overhead will be noticeable.

To get the maximum performance from Stash, we advise configuring automatic build tools to use the http or https protocol, if possible. See Scaling Stash for more information.

Security
To implement SSH authentication support, Stash bundles a version of the Apache Mina SSHD server. Stash's SSH server is not integrated with the SSH server on the host Stash is running on nor does it consider the users on the host when authenticating Stash users. To prevent security issues, the embedded SSH server has been locked down to allow execution of a small set of commands for Git hosting. The only commands that are supported are git upload-pack, git receive-pack, git archive-pack and whoami (a custom whoami implemented in Stash not the whoami command that exists on Linux). It is not possible to open an SSH shell using the embedded server to execute arbitrary commands on the server.

Enabling SSH access
To enable SSH access:
1. Go to the Stash administration area and click Server settings (under 'Settings').
2. Under ‘SSH access’, check SSH enabled.
3. Enter values for SSH port and SSH base URL, according the information in the sections below.
4. Click Save.

SSH base URL
The SSH base URL is the base URL with which users can access the SSH push/pull/clone functionality of Stash.

This is the base URL that Stash will use when displaying SSH URLs to users. If you do not set this, it will default to the host that is set in Stash base URL, with the port that SSH is listening on. See Specifying the base URL for Stash.

For example, if the SSH base URL is not set and the Stash base URL is https://stash.atlassian.com and the SSH port is 7999, the SSH URL for the repository Jira in the project Atlassian will be ssh://git@stash.atlassian.com:7999/ATLASSIAN/jira.git

If you set up port forwarding, you will need to set the SSH base URL to the machine and port that is being forwarded to Stash. However, you do not need to specify the port portion of the URL if the default SSH port (port

✔ Port 22 -> 7999 | https://stash.atlassian.com | https://stash.atlassian.com | 7999 | ssh://git@stash.atlassian.com:7999/ATLASSIAN/jira.git

When running Stash behind a proxy

If you run Stash behind a http proxy such as Apache (e.g. as per our instructions), and if Apache runs on a different host, SSH will not be available on that host. Instead, you will need to set the SSH base URL to the machine Stash is actually running on (and the URL should include the SSH port Stash is serving from).

For example, if the **SSH base URL** is set to `ssh://stash.backend.atlassian.com:7999`, the **SSH URL for the repository Jira in the project Atlassian** will be `ssh://git@stash.backend.atlassian.com:7999/ATLASSIAN/jira.git`

If you set up **port forwarding**, you will need to set the **SSH base URL** to the proxy machine and port that is being forwarded to Stash. However, you do not need to specify the port portion of the URL if the default SSH port (port 22) is being forwarded to Stash.

For example, if you set up port forwarding from your http proxy host, `stash.atlassian.com`, port 22, to `stash.backend.atlassian.com` port 7999, set the **SSH base URL** to `ssh://stash.atlassian.com`. Then, the **SSH URL for the repository Jira in the project Atlassian** will be `ssh://git@stash.atlassian.com/ATLASSIAN/jira.git`

Setting up SSH port forwarding

Why set up port forwarding?

There are two scenarios where you might want to set up port forwarding.

*Remove port numbers from your SSH URLs*

Stash listens for SSH connections on port 7999 by default.

Your users will need to include the port in the URL they use to clone from Stash, for example:

```
git clone ssh://git@stash.mycompany.com:7999/PROJECT/repo.git
```

Rather than have the port number in the URL, you may wish to set up port forwarding so that connections to the default SSH port are forwarded to the port Stash is listening on (e.g. you could forward port 22 to port 7999).

This would allow your users to use a URL without a port number in it, like this:

```
git clone ssh://git@stash.mycompany.com/PROJECT/repo.git
```
Stash is running behind a reverse proxy on a separate machine

You may be following our instructions for setting up Stash behind an Apache front-end.

In this case, your users may not be able to access Stash directly for SSH connections, or if they can, you may wish to make the SSH and HTTPS URLs consistent.

For example, if you have the above topology, without port forwarding (and assuming the default port of 7999), your users will need to clone Stash directly from the backend, like this:

```
git clone ssh://git@stash.backend.atlassian.com:7999/PROJECT/repo.git
```

In your network, the `stash.backend.atlassian.com` machine may not be accessible directly, or you may want the URL to be consistent with the HTTPS URL of `https://stash.atlassian.com/scm/PROJECT/repo.git`.

In this case, you need to set up port forwarding on the `stash.atlassian.com` machine to accept connections and forward them to port 7999 on the `stash.backend.atlassian.com` machine.

How to set up port forwarding

**HAProxy**

Atlassian recommends the use of HAProy for forwarding SSH connections through to Stash.

HAProxy is supported on Linux, Solaris and FreeBSD.

HAProxy is not an Atlassian product, so Atlassian does not guarantee to provide support for its configuration. This section is provided for your information only – use it at your own risk. We recommend that you refer to the HAProy documentation.

**Installing HAProxy**

Your Operating System may support installing HAProy via it's system package manager, such as `apt-get`, `yum` or `rpm`. This will be the easiest way.

Alternatively, you may build HAProy yourself and install it.

1. Download the latest version of HAProy from [http://haproxy.1wt.eu/#down](http://haproxy.1wt.eu/#down).
2. Extract the archive and cd into the directory:

```
tar xzvf haproxy-1.4.21.tar.gz
cd haproxy-1.4.21
```

3. Read the instructions in the README for how to build on your system. This is generally quite simple - on a Linux 64 bit 2.6 Kernel, the command is:
make TARGET=linux26 ARCH=x86_64

4. If it completes successfully, install it following the instructions in the README:

    sudo make install

**Configuring HAProxy**

HAProxy is extremely powerful - it is designed as a HTTPS load balancer, but also can serve as a port forwarder for ssh.

The full documentation for version 1.4 is [here](#). More documentation is available on the [HAProxy web site](#).

An example simple configuration is as follows:

```
global
    daemon
    maxconn 10000

defaults
    timeout connect 500s
    timeout client 5000s
    timeout server 1h

frontend sshd
    bind *:7999
    default_backend ssh
    timeout client 1h

backend ssh
    mode tcp
    server localhost-stash-ssh 127.0.0.1:7999 check port 7999
```

The above configuration will listen on port 7999 (indicated by the `bind` directive) on all network interfaces. As indicated by the `server` directive, traffic is forwarded to 127.0.0.1, port 7999. You will need to replace `127.0.0.1` with the IP address of the machine running Stash.

You can check your configuration by running:

    haproxy -f haproxyconf.txt -c

To run haproxy, simply start it using

    haproxy -f haproxyconf.txt

⚠️ If you use HAProxy to additionally proxy HTTP traffic, ensure that the running `mode` configuration is set to `http`:

```
Using the default SSH port

You can configure HAProxy to listen on the default SSH port instead, so that the port does not need to be specified in the clone URL.

By default, the normal ssh daemon is running on port 22. You have several options:

- Configure HAProxy to listen on an alternate port as in the previous example.
- Configure multiple network interfaces on the physical machine and force the default ssh daemon to listen on all but the interface for accessing Stash. Configure HAProxy to only listen on that interface.
- Move the default ssh daemon to listen on another port and let HAProxy bind on port 22.

We do not provide instructions on the last two options, except for how to configure HAProxy.

Use the same configuration as the last example, but change the bind port to 22, e.g.

```
frontend sshd
  bind *:22
```

You will have to run this configuration as the root user, using _sudo_, because it specifies a port to listen on that is less than 1024.

```
sudo haproxy -f haproxyconf.txt
```

Configuring the SSH base URL

Once port forwarding is set up, you will need to configure the SSH base URL in Stash so that the clone urls presented in Stash indicate the correct host and port to clone from. See the _SSH base URL_ section in Enabling SSH access to Git repositories in Stash.

Proxying and securing Stash

This page provides an overview of some common network topology options for running Stash, including running Stash behind a reverse proxy and securing access to Stash by using HTTPS (HTTP over SSL).

Note that Stash does not need to run behind a web server – it is capable of serving web requests directly using the bundled Tomcat application server. On this page, 'connecting to Stash' really means connecting to Tomcat, which is used to serve Stash content.

**On this page:**

- Connecting to Stash directly over HTTP
- Securing access to Stash using HTTPS
- Using a reverse proxy for Stash
- Securing a reverse proxy using HTTPS

Connecting to Stash directly over HTTP

Connecting directly to Stash (that is, Tomcat) is the default install configuration, as described in the Stash install documentation:
• Installing Stash on Linux and Mac
• Installing Stash on Windows

When set up this way, the user accesses Stash directly over HTTP, without using SSL – all communication between the user’s browser and Stash will be unsecured.

![Diagram of client browser, HTTP, and unsecured Stash server]

You may also wish to consider the following:

• Stash, by default, will listen for requests on port 7990 – this port can be changed if required.
• The address with which to access Stash, by default, will be http://<computer name>:7990. Change the base URL for Stash if required.
• You can set the context path for Stash if you are running another Atlassian application, or Java web application, at the same hostname and context path as Stash.
• Securing Git operations between the user’s computer and Stash is a separate consideration - see Enabling SSH access to Git.

Securing access to Stash using HTTPS

Access to Stash can be secured by enabling HTTPS (HTTP over SSL) for the Tomcat application server that is bundled with Stash. You should consider doing this, and making secure access mandatory, if Stash will be internet-facing and usernames, passwords and other proprietary data may be at risk.

When set up in this way, access to Stash is direct, and all communication between the user’s browser and Stash will be secured using SSL.

See Securing Stash with Tomcat using SSL for configuration details.

![Diagram of client browser, HTTPS, and secured Stash server]

Note that:

• Stash will listen for requests on port 8443, according to the instructions in Securing Stash with Tomcat using SSL. This port can be changed if required.
• The address with which to access Stash, by default, will be https://<computer name>:8443. Change the base URL for Stash if required.
• Any existing links with other applications will need to be reconfigured using this new URL for Stash.
• You can set the context path for Stash if you are running another Atlassian application, or Java web application, at the same hostname and context path as Stash.
• Securing Git operations between the user’s computer and Stash is a separate consideration - see Enabling SSH access to Git.
SSH access to Git.

Using a reverse proxy for Stash

You can run Stash behind a reverse proxy, for example Apache HTTP Server. You may wish to do this if you want to:

- use a different port number to access Stash
- use a different context path to access Stash

When set up this way, external access to Stash is via a reverse proxy, without using SSL. All communication between the user’s browser and Apache, and so Stash, will be unsecured, but users do not have direct access to Stash. An example scenario is where Apache provides a gateway through which users outside the firewall can access Stash.

See Integrating Stash with Apache HTTP Server for configuration details.

Note that:

- Stash, by default, will listen for requests on port 7990 – this port can be changed if required.
- Stash (Tomcat) needs to know the URL (proxy name) that Apache serves.
- The address with which to access Stash will be http://<proxy name>:7990. Change the base URL for Stash if required.
- Any existing links with other applications will need to be reconfigured using this new URL for Stash.
- You can set the context path for Stash if you are running another Atlassian application, or Java web application, at the same hostname and context path as Stash.
- Securing Git operations between the user’s computer and Stash is a separate consideration - see Enabling SSH access to Git.

Securing a reverse proxy using HTTPS

You can run Stash behind a reverse proxy, such as Apache HTTP Server or nginx, that is secured using HTTPS (HTTP over SSL). You should consider doing this, and making secure access mandatory, if usernames, passwords and other proprietary data may be at risk. An example scenario is where Apache HTTP Server provides a gateway through which users outside the firewall can access Stash.

When set up in this way, external access to Stash is via a reverse proxy, where external communication with the proxy uses HTTPS. All communication between the user’s browser and the reverse proxy will be secured, whereas communication between the proxy and Stash will not be secured (it doesn't use SSL).

See the following pages for configuration details:

- Securing Stash with Apache using SSL
- Securing Stash behind nginx using SSL
Note that:

- The reverse proxy (for example, Apache) will listen for requests on port 443.
- Stash, by default, will listen for requests on port 7990. Stash (Tomcat) needs to know the URL (proxy name) that the proxy serves.
- The address with which to access Stash will be https://<proxyName>:<proxyPort>/<context path>, for example https://mycompany.com:443/stash
- Any existing links with other applications will need to be reconfigured using this new URL for Stash.
- Stash (Tomcat) should be configured to refuse requests on port 7990 and to redirect those to the proxy on port 443.
- Securing Git operations between the user's computer and Stash is a separate consideration - see Enabling SSH access to Git.
- It would be possible to set up an SSL connection between the proxy server and Tomcat (Stash), but that configuration is very unusual, and not recommended in most circumstances.
- Incidentally, note that Stash 2.10 and later versions do not support mod_auth_basic.

Securing Stash with Tomcat using SSL

This page is intended for administrators setting up Stash for a small team. It describes how to enable HTTPS (HTTP over SSL) access for Tomcat, the webserver distributed with Stash, using a self-signed certificate. You should consider doing this, and making secure access mandatory, if Stash will be internet-facing and usernames, passwords and other proprietary data may be at risk.

If you are setting up a production instance you should consider using a CA certificate, briefly described below.

There are other network topology options for running Stash, including running Stash behind a reverse proxy. For an overview of some common options, see Proxysing and securing Stash.

When Stash is set up following the instructions on this page, access to Stash is direct, and all communication between the user's browser and Stash will be secured using SSL.

⚠️ Please note that Atlassian Support will refer SSL-related support to the issuing authority for the certificate. The documentation on this page is for reference only.

1. Generate a self-signed certificate

Self-signed certificates are useful where you require encryption but do not need to verify the website identity. They are commonly used for testing and on internal corporate networks (intranets).

Users may receive a warning that the site is untrusted and have to "accept" the certificate before they can access the site. This usually will only occur the first time they access the site.

The following approach to creating a certificate uses Java's keytool, for Java 1.6. Other tools for generating certificates are available.

**To generate a self-signed certificate:**

- Log in with the user account that Stash will run under, and run the following command:

<table>
<thead>
<tr>
<th>Windows</th>
<th>Linux, MacOS and Unix</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;%JAVA_HOME%\bin\keytool&quot; -genkey -alias tomcat -keyalg RSA</td>
<td>$JAVA_HOME/bin/keytool -genkey -alias tomcat -keyalg RSA</td>
</tr>
</tbody>
</table>

  This will create (if it doesn’t already exist) a new .keystore file located in the home directory of the user you used to run the keytool command.

  Note the following:

  - When running the keytool command you will be prompted with: What is your first and last name?

  You must enter the fully qualified hostname of the server running Stash. This is the name you would type in your web browser after 'http://' (no port number) to access your Stash installation. The qualified host name should match the base URL you have set in Stash (without the port number).
1. The keytool utility will also prompt you for two passwords: the keystore password and the key password for Tomcat.

   You must use the same value for both passwords, and the value must be either:
   - "changeit", which is the default value Tomcat expects, or
   - any other value, but you must also specify it in conf/server.xml by adding the following attribute to the <Connector/> tag: `keystorePass="<password value>"

2. Configure HTTPS in Tomcat

   To configure HTTPS in Tomcat:

   1. Edit `conf/server.xml` and, at the bottom, before the </Service> tag, add this section (or uncomment this if it already exists):

   ```
   <Connector port="8443"
     maxHttpHeaderSize="8192"
     SSLEnabled="true"
     maxThreads="150"
     minSpareThreads="25"
     maxSpareThreads="75"
     enableLookups="false"
     disableUploadTimeout="true"
     useBodyEncodingForURI="true"
     acceptCount="100"
     scheme="https"
     secure="true"
     clientAuth="false"
     sslProtocol="TLS" />
   ```

   This enables SSL access on port 8443 (the default for HTTPS is 443, but 8443 is used here instead of 443 to avoid conflicts).

   2. Comment out the existing Connector directive for port 7990 in `conf/server.xml`, so as to disable HTTP access, if you want all access to Stash to make use of HTTPS. That is, comment out this directive:

   ```
   <Connector port="7990"
     protocol="HTTP/1.1"
     connectionTimeout="20000"
     useBodyEncodingForURI="true"
     redirectPort="8443"
     compression="on"
     compressableMimeType="text/html,text/xml,text/plain,text/css,application/json,
     application/javascript,application/x-javascript"
   ```

   3. Start, or re-start, Stash. You will be able to access Stash at `https://localhost:8443/` in your browser.

   Exporting the self-signed certificate

   If Stash will run as the user who ran the `keytool --genkey` command, you do not need to export the certificate.

   You may need to export the self-signed certificate, so that you can import it into a different keystore, if Stash will not be run as the user executing `keytool --genkey`. You can do so with the following command:
If you generate the certificate as one user and run Stash as another, you'll need to do the certificate export as the generating user and the import as the target user.

### Requesting a CA certificate

Digital certificates that are issued by trusted 3rd party CAs (Certification Authorities) provide verification that your website does indeed represent your company.

When running Stash in a production environment, you will need a certificate issued by a CA, such as VeriSign, Trustwave or TrustCenter. The instructions below are adapted from the [Tomcat documentation](http://tomcat.apache.org/download-80.html).

First, you will generate a local certificate and create a 'certificate signing request' (CSR) based on that certificate. You then submit the CSR to your chosen certificate authority. The CA will use that CSR to generate a certificate for you.

1. Use Java's `keytool` utility to generate a local certificate, as described in the section above.
2. Use the `keytool` utility to generate a CSR, replacing the text `<MY_KEYSTORE_FILENAME>` with the path to and file name of the `.keystore` file generated for your local certificate:

   **Windows**
   
   ```
   "%JAVA_HOME%\bin\keytool" -certreq -keyalg RSA -alias tomcat -file certreq.csr -keystore <MY_KEYSTORE_FILENAME>
   ```

   **Linux, MacOS and Unix**
   
   ```
   $JAVA_HOME/bin/keytool -certreq -keyalg RSA -alias tomcat -file certreq.csr -keystore <MY_KEYSTORE_FILENAME>
   ```

3. Submit the generated file called `certreq.csr` to your chosen certificate authority. Refer to the documentation on the CA's website to find out how to do this.
4. The CA will send you a certificate.
5. Import the new certificate into your local keystore. Assuming your certificate is called "file.cer" whether obtained from a CA or self-generated, the following command will add the certificate to the keystore:

   **Windows**
   
   ```
   "%JAVA_HOME%\bin\keytool" -import -alias tomcat -file file.cer
   ```

   **Linux, MacOS and Unix**
   
   ```
   $JAVA_HOME/bin/keytool -import -alias tomcat -file file.cer
   ```

### Troubleshooting

Here are some troubleshooting tips if you are using a self-signed key created by keytool, or a CA certificate, as described above.

When you enter "https://localhost:8443/" in your browser, if you get a message such as "Cannot establish a connection to the server at localhost:8443", look for error messages in your `logs/catalina.out` log file. Here are some possible errors with explanations:

#### SSL + Apache + IE problems

Some people have reported errors when uploading attachments over SSL using IE. This is due to an IE bug, and can be fixed in Apache by setting:
Can't find the keystore

java.io.FileNotFoundException: /home/user/.keystore (No such file or directory)

This indicates that Tomcat cannot find the keystore. The keytool utility creates the keystore as a file called `.keystore` in the current user's home directory. For Unix/Linux the home directory is likely to be `/home/<username>`. For Windows it is likely to be `C:\User\<UserName>`.  

Make sure you are running Stash as the same user who created the keystore. If this is not the case, or if you are running Stash on Windows as a service, you will need to specify where the keystore file is in `conf/server.xml`. Add the following attribute to the connector tag you uncommented:

```xml
keystoreFile="<location of keystore file>"
```

Incorrect password

java.io.IOException: Keystore was tampered with, or password was incorrect

You used a different password than "changeit". You must either use "changeit" for both the keystore password and for the key password for Tomcat, or if you want to use a different password, you must specify it using the `keystorePass` attribute of the Connector tag, as described above.

Passwords don't match

java.io.IOException: Cannot recover key

You specified a different value for the keystore password and the key password for Tomcat. Both passwords must be the same.

Wrong certificate

javax.net.ssl.SSLException: No available certificate corresponds to the SSL cipher suites which are enabled.

If the Keystore has more than one certificate, Tomcat will use the first returned unless otherwise specified in the SSL Connector in `conf/server.xml`. 

Add the `keyAlias` attribute to the Connector tag you uncommented, with the relevant alias, for example:
Using Apache Portable Runtime

APR uses a different SSL engine, and you will see an exception like this in your logs

SEVERE: Failed to initialize connector [Connector[HTTP/1.1-8443]]
LifecycleException: Protocol handler initialization failed: java.lang.Exception: No Certificate file specified or invalid file format

The reason for this is that the APR Connector uses OpenSSL and cannot use the keystore in the same way. You can rectify this in one of two ways:

Use the Http11Protocol to handle SSL connections

Edit the server.xml so that the SSL Connector tag you just uncommented specifies the Http11Protocol instead of the APR protocol:

```xml
<Connector port="8443"
    maxHttpHeaderSize="8192"
    SSLEnabled="true"
    keystoreFile="${user.home}/.keystore"
    maxThreads="150"
    enableLookups="false"
    disableUploadTimeout="true"
    acceptCount="100"
    scheme="https"
    secure="true"
    clientAuth="false"
    sslProtocol="TLS"
    useBodyEncodingForURI="true"
/>```

Configure the Connector to use the APR protocol

This is only possible if you have PEM encoded certificates and private keys. If you have used OpenSSL to generate your key, then you will have these PEM encoded files - in all other cases contact your certificate provider for assistance.
<Connector port="8443"
  maxThreads="200"
  scheme="https"
  secure="true"
  SSLEnabled="true"
  SSLCertificateFile="${user.home}/certificate.pem"
  SSLCertificateKeyFile="${user.home}/key.pem"
  clientAuth="optional"
  SSLProtocol="TLSv1"/>

Enabling client authentication

To enable client authentication in Tomcat, ensure that the value of the **clientAuth** attribute in your **Connector** element of your Tomcat's **server.xml** file is **true**.

```
<Connector ...
  clientAuth="true"
  ... />
```

For more information about **Connector** element parameters, please refer to the 'SSL Support' section of the **Tomcat 6.0** documentation.

Wrong certificate type

If the certificate from the CA is in PKCS12 format, add the **keystoreType** attribute to the SSL Connector in **conf/server.xml**.

```
keystoreFile="/opt/local/wildcard_atlassian_com.p12"
keystorePass="removed"
keystoreType="PKCS12"/
```

Certificate chain is incomplete

If the root certificate and intermediary certificate(s) aren't imported into the keystore before the entity/domain certificate, you will see the following error:

```
[root@dev atlas]\# /usr/java/jdk1.7.0_17/bin/keytool -import -alias tomcat -file my_entity_cert.crt
Enter keystore password:
keytool error: java.lang.Exception: Failed to establish chain from reply
```

Most likely, the CA sent a compressed file containing several certificates. The import order matters so you must import the root certificate first, followed by one or many intermediate certificates, followed lastly by the entity/domain certificate. There are many resources online that provide guidance for certificate installation for Tomcat (Java-based) web servers using keytool.

**Integrating Stash with Apache HTTP Server**

This page explains how to establish a network topology in which Apache HTTP Server acts as a **reverse proxy** for Stash. Typically, such a configuration would be used when Stash is installed in a protected zone 'behind the firewall', and Apache HTTP Server provides a gateway through which users outside the firewall can access Stash. You may wish to do this if you want to:

- use a different port number to access Stash
- use a different context path to access Stash
Be aware that Stash does not need to run behind a web server, since it is capable of serving web requests directly; to secure Stash when run in this way see Securing Stash with Tomcat using SSL. For an overview of other network topology options, see Proxying and securing Stash. Otherwise, if you want to install Stash in an environment that incorporates Apache HTTP Server, this document is for you.

When Stash is set up following the instructions on this page, external access to Stash is via a reverse proxy, without using SSL. All communication between the user's browser and Apache, and so Stash, will be unsecured, but users do not have direct access to Stash.

About using Apache software

This section has general information pertaining to the use of Apache HTTP Server and Apache Tomcat. It is important that you read this section before proceeding to the steps that follow.

Configuring Tomcat 7

The Stash distribution includes an instance of Tomcat 7, the configuration of which is determined by the contents of the server.xml file, which can be found in the conf directory immediately under the Stash installation.
directory. Note that any changes that you make to the server.xml file will be effective upon starting or re-starting Stash.

You may find it helpful to refer to the Apache Tomcat 7.0 Proxy Support HowTo page.

**Configuring Apache HTTP Server**

⚠️ Since Apache HTTP Server is not an Atlassian product, Atlassian does not guarantee to provide support for its configuration. You should consider the material on this page to be for your information only; use it at your own risk. If you encounter problems with configuring Apache HTTP Server, we recommend that you refer to the Apache HTTP Server Support page.

Note that Stash 2.10 and later versions do not support mod_auth_basic.

You may find it helpful to refer to the Apache HTTP Server Documentation, which describes how you can control Apache HTTP Server by changing the contents of the httpd.conf file. The section on Apache Module mod_proxy is particularly relevant. Note that any changes you make to the httpd.conf file will be effective upon starting or re-starting Apache HTTP Server.

This document relates to Apache HTTP Server version 2.4.2; the configuration of other versions may differ.

**Step 1: Configure the Tomcat Connector**

Find the normal (non-SSL) Connector directive in Tomcat's server.xml file, and add the scheme, proxyName, and proxyPort attributes as shown below. Instead of mycompany.com, set the proxyName attribute to your domain name that Apache HTTP Server will be configured to serve. This informs Stash of the domain name and port of the requests that reach it via Apache HTTP Server, and is important to the correct operation of the Stash functions that construct URLs.

```xml
<Connector port="7990"
    protocol="HTTP/1.1"
    connectionTimeout="20000"
    useBodyEncodingForURI="true"
    redirectPort="8443"
    compression="on"
    compressableMimeType="text/html,text/xml,text/plain,text/css,application/json,application/javascript,application/x-javascript"
    scheme="http"
    proxyName="mycompany.com"
    proxyPort="80" />
```

**Note:** Apache HTTP Server's `ProxyPreserveHost` directive is another way to have the hostname of the incoming request recognised by Stash instead of the hostname at which Stash is actually running. However, the `ProxyPreserveHost` directive does not cause the scheme to be properly set. Since we have to mess with Tomcat's Connector directive anyway, we recommend that you stick with the above-described approach, and don't bother to set the `ProxyPreserveHost` in Apache HTTP Server.

For more information about configuring the Tomcat Connector, refer to the Apache Tomcat 7.0 HTTP Connector Reference.

**Step 2: Change Stash's base URL**

After re-starting Stash, open a browser window and log into Stash using an administrator account. Go to the Stash administration area and click Server settings (under 'Settings'), and change Base URL to match the proxy URL (the URL that Apache HTTP Server will be serving).

**Step 3 (optional): Set a context path for Stash**

By default, Stash is configured to run with an empty context path; in other words, from the 'root' of the server's
name space. In that default configuration, Stash is accessed at:

http://localhost:7990/

It’s perfectly fine to run Stash with the empty context path as above. Alternatively, you can set a context path by changing the Context directive in Tomcat’s server.xml file:

```xml
<Context path="/stash" docBase="${catalina.home}/atlassian-stash"
reloadable="false" useHttpOnly="true">

....
</Context>
```

If you do set a context path, it is important that the same path be used in Step 5, when setting up the ProxyPass and ProxyPassReverse directives. You should also append the context path to Stash’s base URL (see Step 2).

Step 4: Enable mod_proxy and mod_proxy_http in Apache HTTP Server

In the mod_proxy documentation, you will read that mod_proxy can be used as a forward proxy, or as a reverse proxy (gateway); you want the latter. Where the mod_proxy documentation mentions ‘origin server’, it refers to your Stash server. Unless you have a good reason for doing otherwise, load mod_proxy and mod_proxy_http dynamically, using the LoadModule directive; that means un-commenting the following lines in the httpd.conf file:

```
LoadModule proxy_module modules/mod_proxy.so
LoadModule proxy_http_module modules/mod_proxy_http.so
```

Experienced administrators may be aware of the Apache Connector module, mod_jk. Atlassian does not recommend use of the mod_jk module with Stash, since it has proven itself to be less reliable than mod_proxy.

Step 5: Configure mod_proxy to map requests to Stash

To configure mod_proxy for use with Stash, you need to use the ProxyPass and ProxyPassReverse directives in Apache HTTP Server’s httpd.conf file as follows:

```
ProxyPass        / http://localhost:7990/ connectiontimeout=5 timeout=300
ProxyPassReverse / http://localhost:7990/
```

Suppose Apache HTTP Server is configured to serve the mycompany.com domain; then the above directives tell Apache HTTP Server to forward web requests of the form http://mycompany.com/* to the Tomcat connector (Stash) running on port 7990 on the same machine.

The connectiontimeout attribute specifies the number of seconds Apache HTTP Server waits for the creation of a connection to Stash.

The timeout attribute specifies the number of seconds Apache HTTP Server waits for data to be sent to Stash.

If you set up a context path for Stash in Step 3, you’ll need to use that context path in your ProxyPass and ProxyPassReverse directives. Suppose your context path is set to "/stash", the directives would be as follows:

```
ProxyPass        /stash http://localhost:7990/stash connectiontimeout=5 timeout=300
ProxyPassReverse /stash http://localhost:7990/stash
```

If Stash is to run on a different domain and/or different port, you should use that domain and/or port number in the ProxyPass and ProxyPassReverse directives; for example, suppose that Stash will run on port 9900 on...
private.mycompany.com under the context path /stash, then you would use the following directives:

```conf
timeout=300
```

Step 6: Configure mod_proxy to disable forward proxying

If you are using Apache HTTP Server as a reverse proxy only, and not as a forward proxy server, you should turn forward proxying off by including a `ProxyRequests` directive in the `httpd.conf` file, as follows:

```conf
ProxyRequests Off
```

Step 7: Allow proxying to Stash from everywhere

Strictly speaking, this step is unnecessary because access to proxied resources is unrestricted by default. Nevertheless, we explicitly allow access to Stash from any host so that this policy will be applied regardless of any subsequent changes to access controls at the global level. Use the `Proxy` directive in the `httpd.conf` file as follows:

```conf
<Proxy *>
    Order Deny,Allow
    Allow from all
</Proxy>
```

The `Proxy` directive provides a context for the directives that are contained within its delimiting tags. In this case, we specify a wild-card url (the asterisk), which applies the two contained directives to all proxied requests.

The `Order` directive controls the order in which any `Allow` and `Deny` directives are applied. In the above configuration, we specify "Deny,Allow", which tells Apache HTTP Server to apply any `Deny` directives first, and if any match, the request is denied unless it also matches an `Allow` directive. In fact, "Deny,Allow" is the default; we include it merely for the sake of clarity. Note that we specify one `Allow` directive, which is described below, and don't specify any `Deny` directives.

The `Allow` directive, in this context, controls which hosts can access Stash via Apache HTTP Server. Here, we specify that all hosts are allowed access to Stash.

Step 8 (optional): Configure Apache HTTP Server for SSL

If you want to set up SSL access to Stash, follow the instructions on [Securing Stash with Apache using SSL](https://confluence.atlassian.com/display/STASH/Securing+Stash+with+Apache+using+SSL). When you are finished, users will be able to make secure connections to Apache HTTP Server; connections between Apache HTTP Server and Stash will remain unsecured (not using SSL). If you don't want to set up SSL access, you can skip this section entirely.

**Note:** It would be possible to set up an SSL connection between Apache HTTP Server and Tomcat (Stash), but that configuration is very unusual, and not recommended in most circumstances.

A note about application links

When an application link is established between Stash and another Atlassian product (e.g. JIRA), and Stash is operating 'behind' Apache HTTP Server, the link from the other product to Stash must be via the proxy URL; that is, the 'reciprocal URL' from, say JIRA, to Stash must match the proxy name and port that you set at Step 1.

Troubleshooting

- On **Fedora Core 4**, people have reported 'permission denied' errors when trying to get mod_proxy (and mod_jk) working. Disabling SELinux (/etc/selinux/config) apparently fixes this.
- Some users have reported problems with user sessions being hijacked when the `mod_cache` module is enabled. If you have such problems, disable the `mod_cache` module. Note that this module is enabled by
default in some Apache HTTP Server version 2 distributions.

- In general, if you are having problems:
  1. Ensure that Stash works as expected when running directly from Tomcat on http://localhost:7990/stash.
  2. Watch the log files (usually in /var/log/httpd/ or /var/log/apache2/). Check that you have a LogLevel directive in your httpd.conf, and turn up logging ('LogLevel debug') to get more info.
  3. Check out the Stash Knowledge Base.

### Securing Stash with Apache using SSL

You can run Stash behind a reverse proxy, such as Apache HTTP Server or nginx, that is secured using HTTPS (HTTP over SSL). You should consider doing this, and making secure access mandatory, if usernames, passwords and other proprietary data may be at risk.

There are other network topology options for running Stash; for an overview of some common options, see Prox ying and securing Stash.

When Stash is set up following the instructions on this page, external access to Stash is via Apache HTTP Server as a reverse proxy, where external communication with the proxy uses HTTPS. All communication between the user's browser and Apache will be secured, whereas communication between Apache and Stash will not be secured (it doesn't use SSL).

- The steps on this page would normally be performed after integrating Stash with Apache HTTP Server.

**On this page:**
- Step 1: Configure the Tomcat Connector for SSL
- Step 2: Set up a virtual host in Apache HTTP Server
- Step 3: Create SSL certificate and key files
- Step 4: Update the base URL for 'https'
- Using a self-signed certificate

**Related pages:**
- Integrating Stash with Apache HTTP Server
- Securing Stash with Tomcat using SSL
- Securing Stash behind nginx using SSL

Note that:
- The reverse proxy (for example, Apache) will listen for requests on port 443.
- Stash, by default, will listen for requests on port 7990. Stash (Tomcat) needs to know the URL (proxy name) that the proxy serves.
- The address with which to access Stash will be https://<proxyName>:<proxyPort>/<context path>, for example https://mycompany.com:443/stash
- Any existing links with other applications will need to be reconfigured using this new URL for Stash.
- Stash (Tomcat) should be configured to refuse requests on port 7990 and to redirect those to the proxy on port 443.
- Securing Git operations between the user's computer and Stash is a separate consideration - see Enablin g SSH access to Git.
It would be possible to set up an SSL connection between the proxy server and Tomcat (Stash), but that configuration is very unusual, and not recommended in most circumstances.

Incidentally, note that Stash 2.10 and later versions do not support `mod_auth_basic`.

Step 1: Configure the Tomcat Connector for SSL

Find the normal (non-SSL) Connector directive in Tomcat's `server.xml` file, and change the `redirectPort`, `scheme`, `proxyName` and `proxyPort` attributes as follows:

```xml
<Connector port="7990"
    protocol="HTTP/1.1"
    connectionTimeout="20000"
    useBodyEncodingForURI="true"
    redirectPort="443"
    compression="on"

    compressableMimeType="text/html,text/xml,text/plain,text/css,application/json,application/javascript,application/x-javascript"
    secure="true"
    scheme="https"
    proxyName="mycompany.com"
    proxyPort="443" />
```

The `redirectPort` directive causes Tomcat-initiated redirections to secured resources to use the specified port. Right now, the Stash configuration of Tomcat does not involve Tomcat-initiated redirections, so the change to `redirectPort` is redundant. Nevertheless, we suggest that you change it as directed above for the sake of completeness.

Start, or restart, Stash.

Step 2: Set up a virtual host in Apache HTTP Server

Un-comment the following LoadModule directive in Apache HTTP Server's `httpd.conf` file:

```conf
LoadModule ssl_module modules/mod_ssl.so
```

Add the following directives to the `httpd.conf` file:

```conf
Listen 443
<VirtualHost *:443>
    SSLEngine On
    SSLCertificateFile    "/usr/local/apache2/conf/server.crt"
    SSLCertificateKeyFile "/usr/local/apache2/conf/server.key"
    SSLCertificateChainFile  "/usr/local/apache2/conf/server.crt"
    ProxyPass        / http://localhost:7990/ connectiontimeout=5 timeout=300
    ProxyPassReverse / http://localhost:7990/
</VirtualHost>
```

The `Listen` directive instructs Apache HTTP Server to listen for incoming requests on port 443. Actually, we could omit that directive in this case, since Apache HTTP Server listens for https requests on port 443 by default. Nevertheless, it's good to make one's intentions explicit.

The `VirtualHost` directive encloses a number of child directives that apply only and always to requests that arrive at port 443. Since our `VirtualHost` block does not include a `ServerName` directive, it inherits the server name from the main server configuration.

The `SSLEngine` directive toggles the use of the SSL/TLS Protocol Engine. In this case, we're using it to turn SSL on for all requests that arrive at port 443.
The **SSLCertificateFile** directive tells Apache HTTP Server where to find the PEM-encoded certificate file for the server.

The **SSLCertificateKeyFile** directive tells Apache HTTP Server where to find the PEM-encoded private key file corresponding to the certificate file identified by the **SSLCertificateFile** directive. Depending on how the certificate file was generated, it may contain a RSA or DSA private key file, making the **SSLCertificateKeyFile** directive redundant; however, Apache strongly discourages that practice. The recommended approach is to separate the certificate and the private key. If the private key is encrypted, Apache HTTP Server will require a pass phrase to be entered when it starts up.

The **SSLCertificateChainFile** is optional. Please consult with the CA vendor to verify if this is required. This directive sets the optional all-in-one file where you can assemble the certificates of Certification Authorities (CA) which form the certificate chain of the server certificate.

The **ProxyPass** and **ProxyPassReverse** directives should be set up in the manner described in Step 5 of the Integrating Stash with Apache HTTP Server page. In particular, if Stash is to run on a separate machine from Apache, you should use that domain (and perhaps the port number and context path) in the **ProxyPass** and **ProxyPassReverse** directives.

For more information about the support for SSL in Apache HTTP Server, refer to the [Apache SSL/TLS Encryption manual](http://httpd.apache.org/docs/2.1/tls/). In addition, you will find lots of relevant information in the `<apache directory>/conf/extra/httpd-ssl.conf` file, which is included in the standard Apache distribution.

Start, or restart, Apache.

**Step 3: Create SSL certificate and key files**

In Step 2, you specified `server.crt` and `server.key` as the certificate file and private key file respectively. Those two files must be created before we can proceed. This step assumes that OpenSSL is installed on your server.

Generate a server key file:

```
openssl genrsa -des3 -out server.key 1024
```

You will be asked to provide a password. Make sure that the password is strong because it will form the one real entry point into the SSL encryption set-up. **Make a note of the password because you'll need it when starting Apache HTTP Server later.**

If you don't wish to specify a password, don't use the `-des3` option in the command above.

Generate a certificate request file (`server.csr`):

```
openssl req -new -key server.key -out server.csr
```

Generate a self-signed certificate (`server.crt`):

```
openssl x509 -req -days 365 -in server.csr -signkey server.key -out server.crt
```

The above command generates a self-signed certificate that is valid for one year. You can use the certificate signing request to purchase a certificate from a certificate authority. For testing purposes though, the self-signed certificate will suffice. Copy the certificate file and private key file to the locations you specified in Step 2.

```
cp server.key /usr/local/apache2/conf/
cp server.crt /usr/local/apache2/conf/
```

**Step 4: Update the base URL for 'https'**
Open a browser window and log into Stash using an administrator account. Go to the Stash administration area and click **Server settings** (under 'Settings'). Change **Base URL** to use 'https', for example, "https://stash.mycompany.com").

**Using a self-signed certificate**

There are two implications of using the self-signed certificate:

- When you access Stash in a web browser, you can expect a warning to appear, alerting you that an un-trusted certificate is in use. Before proceeding you will have to indicate to the browser that you trust the certificate.
- When you perform a git clone operation, SSL verification will fail.

The SSL verification error message will look something like this:

```
error:14090086:SSL routines:SSL3_GET_SERVER_CERTIFICATE:certificate verify failed while accessing https://justme@mycompany/git/TP/test.git
```

It's easy to fix. Turn SSL verification off for individual git operations by setting the **GIT_SSL_NO_VERIFY** environment variable. In Unix, you can set the variable in-line with git commands as follows:

```
GIT_SSL_NO_VERIFY=true git clone https://justme@mycompany/git/TP/test.git
```

In Windows you have to set the variable in a separate shell statement:

```
set GIT_SSL_NO_VERIFY=true
```

```
git clone https://justme@mycompany/git/TP/test.git
```

Once you have purchased and installed a signed certificate from a certificate authority, you will no longer have to include the **GIT_SSL_NO_VERIFY** modifier.

**Securing Stash behind nginx using SSL**

This page describes how to establish a network topology in which the nginx server acts as a reverse proxy for Stash. Typically, such a configuration would be used when Stash is installed in a protected zone 'behind the firewall', and nginx provides a gateway through which users outside the firewall can access Stash.

The configuration described on this page results in a scenario where:

- External client connections with nginx are secured using SSL. Connections between nginx and Stash are unsecured.
- Stash and nginx run on the same machine.
- Stash is available at **https://mycompany.com:7990/stash**.

**On this page:**
- Step 1: Configure the Tomcat Connector
- Step 2: Set a context path for Stash
- Step 3: Change Stash's base URL
- Step 4: Configure nginx

Please note that:

- We assume that you already have a running instance of nginx. If not, refer to the nginx documentation for instructions on downloading and installing nginx.
- SSL certificates must be installed on the server machine.
- Any existing links with other applications will need to be reconfigured using the new URL for Stash.
- Securing Git operations between the user's computer and Stash is a separate consideration - see Enabling SSH access to Git.
Be aware that Stash does not need to run behind a web server, since it is capable of serving web requests directly; to secure Stash when run in this way see Securing Stash with Tomcat using SSL. Otherwise, if you want to install Stash in an environment that incorporates nginx, this document is for you. (You can of course run Stash behind nginx without securing client connections to nginx using SSL – we don't describe this option on this page.)

Note that the Atlassian Support Offering does not cover nginx integration. Assistance with nginx may be obtained through the Atlassian community from answers.atlassian.com or from an Atlassian Expert.

Step 1: Configure the Tomcat Connector

Find the normal (non-SSL) Connector directive in Tomcat's server.xml file, and add the scheme, proxyName, and proxyPort attributes as shown below. Instead of mycompany.com, set the proxyName attribute to your domain name that the nginx server will be configured to serve. This informs Stash of the domain name and port of the requests that reach it via nginx, and is important to the correct operation of the Stash functions that construct URLs.

```xml
<Connector port="7990"
  protocol="HTTP/1.1"
  connectionTimeout="20000"
  useBodyEncodingForURI="true"
  redirectPort="443"
  compression="on"
  compressableMimeType="text/html,text/xml,text/plain,text/css,application/json,application/javascript,application/x-javascript"
  secure="true"
  scheme="https"
  proxyName="mycompany.com"
  proxyPort="443" />
```

For more information about configuring the Tomcat Connector, refer to the Apache Tomcat 7.0 HTTP Connector Reference.

Step 2: Set a context path for Stash

By default, Stash is configured to run with an empty context path; in other words, from the 'root' of the server's name space. In that default configuration, Stash would be accessed at:

http://mycompany.com:7990/

For the example configuration on this page, we want Stash to be accessed at:

https://mycompany.com:7990/stash

In Tomcat's server.xml file, set the context path to /stash:

```xml
<Context path="/stash" docBase="${catalina.home}/atlassian-stash"
  reloadable="false" useHttpOnly="true">
  ....
</Context>
```

If you use a context path, it is important that the same path is:

- appended to the context path of Stash's base URL (Step 3).
- used when setting up the location for the proxy_pass directive (Step 4).

Step 3: Change Stash's base URL

After re-starting Stash, open a browser window and log into Stash using an administrator account. Go to the
Stash administration area and click **Server settings** (under ‘Settings’), and change **Base URL** to match the proxy URL (the URL that the nginx server will be serving).

For this example, use http://mycompany.com:7990/stash (Note the context path with this.)

**Step 4: Configure nginx**

Edit /etc/nginx/nginx.conf, using the example server configuration below, to configure nginx as a proxy server.

Put the `proxy_pass` directive in the location block, and specify the protocol, name and port of the proxied server in the parameter (in our case, it is http://localhost:7990):

```plaintext
server {
  listen          443;
  server_name     mycompany.com;

  ssl            on;
  ssl_certificate <path/to/your/certificate>;
  ssl_certificate_key <path/to/your/certificate/key>;
  ssl_session_timeout 5m;
  ssl_protocols     SSLv2 SSLv3 TLSv1 TLSv1.1 TLSv1.2;
  ssl_ciphers     RC4:HIGH:!aNULL:!MD5;
  ssl_prefer_server_ciphers on;

  location /stash {
    proxy_pass    http://localhost:7990/stash;
    proxy_set_header  X-Forwarded-Host $host;
    proxy_set_header  X-Forwarded-Server $host;
    proxy_set_header    X-Forwarded-For $proxy_add_x_forwarded_for;
    proxy_set_header    X-Real-IP $remote_addr;
    proxy_redirect   off;
  }
}
```

Changes made in the configuration file will not be applied until the command to reload configuration is sent to nginx or it is restarted. To reload the configuration, execute:

```
nginx -s reload
```

This command should be executed under the same user that started nginx.

**Resources**

You may find the following resources helpful in setting up Stash behind nginx:

**Moving Stash to a different context path**

There are various reasons why you may wish to change the context path for Stash. Two of those are:

- You are running Stash behind a proxy.
- You have another Atlassian application, or Java web application, available at the same hostname and context path as Stash, and are experiencing login problems (see Login and session conflicts with multiple Atlassian applications).
Changing the context path for Stash:

1. Navigate to the directory where you are running Stash from. This is the install directory that you extracted the Stash distribution to, not your Stash home directory.
2. Stop Stash. This can be done using `bin/stop-stash.bat` on Windows or `bin/stop-stash.sh` on OSX or Linux.
3. Edit `conf/server.xml` and find the element below:

   ```xml
   <Context path="" docBase="${catalina.home}/atlassian-stash" reloadable="false" useHttpOnly="true"/>
   ```

   Update the `path` attribute to reflect the context path that you want Stash to be accessible at, e.g. `/stash`:

   ```xml
   <Context path="/stash" docBase="${catalina.home}/atlassian-stash" reloadable="false" useHttpOnly="true"/>
   ```

   Then save the file.

4. Start Stash. This can be done using `bin/start-stash.bat` on Windows or `bin/start-stash.sh` on OSX or Linux.

   Stash should now be available at the same host as before under the new context path. For example a server that was at `http://localhost:7990` will now be reachable at `http://localhost:7990/stash`.

5. Once Stash has started, go to the administration area and click **Server Settings** (under 'Settings'). Append the new context path to your base URL:

   ```
   https://my-stash-hostname:7990/stash
   ```

6. Click **Save**.

**Upgrade Note**

Since the manual steps of this process modify the Stash distribution, you will need to repeat Steps 1-6 each time you upgrade Stash. See the [Stash upgrade guide](#).

**Stash + Apache**

Note that if you are running Stash behind Apache:

- You will need to make sure that the host or context path that Stash is exposed on is not also being used by another web application that is listening on a different port.
- If you have updated the Stash context path using the steps outlined above, you will need to update your Apache configuration, as described in [Integrating Stash with Apache HTTP Server](#).

**Application Links**

If you had Application Links set up before changing the context path in Stash, you will have to recreate those using the new Stash URL. See [Linking Stash with JIRA](#).
Changing the port that Stash listens on

You may wish to change the port that Stash listens on from the default '7990' to a different value if another application is already running on that port.

To change the port, edit the `conf\server.xml` file in the `<Stash installation directory>`.

Find the following lines in `server.xml`:

```
<Server port="8006" shutdown="SHUTDOWN">
...
<Connector port="7990" protocol="HTTP/1.1"
    connectionTimeout="20000"
    useBodyEncodingForURI="true"
    redirectPort="8443"
    compression="on"
    compressableMimeType="text/html,text/xml,text/plain,text/css,application/json"/>
```

You need to modify both the server port (default is 8006) and the connector port (default is 7990) to ports that are free on your machine. The server port is required by Tomcat but is not user-facing in any way. The connector port is the port you use to access Stash. For example, in the snippet above, the URL would be `http://example.com:7990`.

- **Hint:** You can use `netstat` to identify free ports on your machine. See more information on using `netstat` on [Windows](#) or on [Linux](#).

- **Warning:** If you are using a firewall, you should ensure that it is configured to allow http/https traffic over the connector port you have chosen.

Running Stash with a dedicated user

For production installations, we recommend that you create a new dedicated user that will run Stash on your system. This user:

- Should be local.
- Should **not** have admin privileges.
- Should be a non-privileged user with read, write and execute access on the Stash install directory and home directory.
- Should only have read access to your repositories.

See also Running Stash as a Windows service and Running Stash as a Linux service.

For **Linux**, here is an example of how to create a dedicated user to run Stash:

```
$ sudo /usr/sbin/useradd --create-home --home-dir /usr/local/Stash --shell /bin/bash Stash
```

Data recovery and backups

This page provides an overview of the backup and restore strategies that Atlassian recommends for use with Stash:

- Stash backup essentials
- Two ways to back up Stash
- How Stash backup and restore works

Questions? Check out FAQ - Data recovery and backup.
Stash backup essentials

An effective backup strategy is essential:

- for avoiding data loss in the event of any system breakdown
- for restoring Stash after any system breakdown
- as part of the Stash upgrade process.

We highly recommend that you establish a data recovery plan that is aligned with your company’s policies.

It is important to understand that there is a tight coupling between the Stash file system on disk and the database that Stash uses.

The following types of data are stored:

- The Stash home directory on the file system contains data about your repositories, as well as cache and log files (see Stash home directory for more detail).
- The Stash database contains data about pull requests (pointers to branches in the repos, comments and pull request diffs) and user management.

Any backup strategy that captures both the file system and database while Stash is still available to users runs the risk that the backed up Git repositories are corrupted or that the data in the database doesn’t reflect the repository state on disk. Therefore, strategies for backing up and restoring Stash data must keep the repository data and the database perfectly synchronised.

With any strategy, you should schedule the backup window so as to minimise the impact on Stash availability. You might consider checking the access logs to determine patterns of lowest usage to help with this.

Two ways to back up Stash

When it comes to backing up, every organization has slightly different policies and requirements. Some organizations will want a backup solution that just works with minimal intervention, is independent of the underlying database and file system configuration, and don’t mind a little downtime when the backup is run as part of a nightly maintenance schedule. Other organizations will have more specific policies and requirements surrounding the use of vendor-specific database and storage backup tools, the maximum acceptable downtime, the format of backups, and where the backups are ultimately stored.

To cater for these different policies and requirements, Stash provides two different backup strategies:

- the Stash Backup Client,
- Stash DIY Backup.

The features of each backup strategy are summarized in the following table:

<table>
<thead>
<tr>
<th>Audience</th>
<th>Stash Backup Client</th>
<th>Stash DIY Backup</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Recommended for most people without specific backup policies and requirements.</td>
<td>Recommended for developers and system administrators who wish to minimize downtime and/or customize the Stash backup process for their specific database and file system configuration.</td>
</tr>
<tr>
<td>Usage</td>
<td>Ready to use out of the box.</td>
<td>Requires you to write some code (in your preferred language) to perform the backup steps.</td>
</tr>
</tbody>
</table>
# How Stash backup and restore works

Whether you use the Stash Backup Client or Stash DIY Backup, the backup process must ensure that you keep the repository data and the database perfectly synchronised, by:

- Shutting down Stash before performing the backup.
- Restoring the database and file system at the same time.
- Using the same version or snapshot of the database and file system.

## Backing up Stash when using the internal database

When Stash uses the built-in HSQL database, the database files are stored in the Stash file system. See Stash home directory for more detail.

Making a backup of Stash involves copying the Stash home directory.

Note that Atlassian does not recommend using the internal database for a production instance.

## Backing up Stash when using an external database

When Stash uses an external database, both the Stash home directory and the external database must be backed up.

If you use the Stash Backup Client, the external database is automatically included as part of the backup in a vendor-independent format.

If you use Stash DIY Backup, you have full control over the database backup tools and procedures, and can use your database vendor’s specific backup tooling that is optimized for your database back end and stores the dump in a vendor-specific format.

## Restoring Stash from a cold backup

Whether you use the Stash Backup Client or Stash DIY Backup, recovering a Stash instance from backup requires restoring both:

1. the file system backup, and
2. the database backup.

If you use the Stash Backup Client, these components are both automatically included when you run the Stash Restore Client.

If you use Stash DIY Backup, the backup script restores the file system backup, and you need to use your database vendor’s specific restore tooling to restore the database backup.

## Using the Stash Backup Client

This page describes using the Stash Backup Client, which has been supported from Stash 2.8 and is the backup strategy that Atlassian recommends for most people.

For information about other backup strategies for Stash, see Data recovery and backups. That page also discusses the tight coupling between the Stash file system on disk and the database that Stash uses.

With any strategy, you should consider scheduling the backup window so as to minimise the impact on Stash availability. You might consider checking the access logs to determine patterns of lowest usage to help with this.

We highly recommend that you establish a data recovery plan that is aligned with your company’s policies.

How it works

The Backup Client implements a common and universal way to back up a Stash instance, and does the following:

1. Locks access to the Stash application, the repositories managed by Stash and the Stash database for the entire duration of the back up. This state is called 'maintenance mode'.
2. Checks that all Git and database operations have completed.
3. Performs an application-specific backup of the Stash home directory and the Stash database. The backup is generic and does not depend on the server or database configuration.
4. Stores the backup as a single tar file on the local filesystem in the specified location.
5. Unlocks Stash from maintenance mode.

A user will get an error message if they try to access the Stash web interface, or use the Stash hosting services, when Stash is in maintenance mode.

The client supports Windows and Linux platforms, and Stash versions 2.7 and higher, but does not provide ways to integrate with your organizations IT policies or processes.

As an indication of the unavailability time that can be expected when using the Stash Backup Client, in our testing and internal use we have seen downtimes for Stash of 7–8 minutes with repositories totalling 6 GB in size. For comparison, using Stash DIY Backup for the same repositories typically results in a downtime of less than a minute.

What is backed up

The Backup Client backs up all the following data:

- the database Stash is connected to (either the internal or external DB)
- managed Git repositories
- the Stash audit logs
- installed plugins and their data

The backup does NOT include the following files and directories:
1. **export/**
2. **log/** (except for the audit logs)
3. **data/db/** (HSQL data in the DB is backed up, but the files on disk are not)
4. **tmp**
5. **the plugins directory** (except for the **installed-plugins** directory)

Note that the **caches** directory is included in the backup because it contains previously indexed heads.

### Backing up Stash using the client

The Backup Client must be run from somewhere with access to the Stash home directory. Usually, you will run the Backup Client directly on the Stash server. Run the client with the following command:

```
java -jar <path/to/stash-backup-client.jar>
```

Configuration options are kept in the **backup-config.properties** file that is included with the client – this file is automatically read when the client is run. The required properties include:

Alternatively, these properties can be given on the command-line, when they need to be prefixed with "-D", and be placed before the "-jar" parameter. For example:

```
java -Dstash.password="pass" -Dstash.user="user" -Dstash.baseUrl="http://stash" -jar stash-backup-client.jar
```

### Cancelling the client backup

You can cancel the running client backup operation if necessary.

**To cancel the backup:**

1. Copy the cancel token echoed by the client in the terminal (or the Command Prompt on Windows):

2. Go to the Stash interface in your browser. Stash will display this screen:

3. Click **Cancel backup**, and enter the cancel token:
4. Click **Cancel backup**.

**Restoring Stash into the backed-up DB instance**

In order to ensure accidental restores do not delete existing data, the restore client will only restore into an empty home directory and an empty database. Therefore, if you intend to perform the restore into the current environment, make sure that these prerequisites are met.

Run the client with the following command:

```
java -Dstash.home="path/to/stash/home" -jar stash-restore-client.jar
```

**Restoring Stash into a newly created DB instance**

When restoring Stash, the restore client must be run on the machine that Stash should be restored to. In order to ensure accidental restores do not delete existing data, the restore client will only restore into an empty home directory and an empty database.

The new database should be configured following the instructions in **Connecting Stash to an external database** and its sub-page that corresponds to your database type.

---

**If you are using MySQL**

**Download and install the JDBC driver**

The JDBC drivers for MySQL are *not* bundled with the Backup Client (due to licensing restrictions). You need to download and install the driver yourself.

1. Download the MySQL Connector/J JDBC driver from the download site.
2. Expand the downloaded zip/tar.gz file.
3. Copy the mysql-connector-java-5.1.XX-bin.jar file from the extracted directory to your `<path/to/backup/client>/jdbc` directory.

The restore client also uses the **backup-config.properties** file, where the properties can include:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stash.home</td>
<td>The full path to a directory that the restore client will populate with the Stash home data. This directory must be empty. On Windows, you must use two backslashes (<code>\</code>) or a single forward slash (<code>/</code>) to separate paths.</td>
</tr>
</tbody>
</table>
jdbc.override

By default, the restore client will restore into the same database that was backed up. If jdbc.override is set to true, the restore client will restore into the database specified by the jdbc properties in the table below. The database must be empty.

jdbc.driver

The driver class that Stash should use to login to the new database. See examples below.

jdbc.url

The connection details for the new database, formatted as a JDBC URL. See examples below.

jdbc.user

The username that Stash should use to login to the new database.

jdbc.password

The username that Stash should use to login to the new database.

Sample JDBC properties

Sample jdbc.driver and jdbc.url properties are shown below:

<table>
<thead>
<tr>
<th>Database</th>
<th>jdbc.driver</th>
<th>jdbc.url</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle</td>
<td>oracle.jdbc.driver.OracleDriver</td>
<td>jdbc:oracle:thin:@//HOSTNAME:PORT/SERVICE</td>
</tr>
<tr>
<td>PostgreSQL</td>
<td>org.postgresql.Driver</td>
<td>jdbc:postgresql://HOSTNAME:PORT/DATABASE</td>
</tr>
<tr>
<td>SQL Server</td>
<td>com.microsoft.sqlserver.jdbc.SQLServerDriver</td>
<td>jdbc:sqlserver://HOSTNAME:PORT;databaseName=DATABASE;</td>
</tr>
</tbody>
</table>

Setting JDBC properties on the command line

You can also set JDBC properties on the command line with the following command:

```
java -Djdbc.override=true -Djdbc.driver=org.postgresql.Driver
-Djdbc.url=jdbc:postgresql://HOSTNAME:PORT/DATABASE -Djdbc.user=dbuser
-Djdbc.password=dbpasswd -Dstash.home="path/to/stash/home" -jar
/path/to/stash-restore-client.jar /path/to/original/backup/file
```

Using Stash DIY Backup

Stash DIY Backup was introduced in Stash 2.12 as an alternative strategy to using the Stash Backup Client. It allows you to:

- significantly reduce the downtime needed to create a consistent backup,
- use the vendor-specific database backup tool appropriate to your back end database, for example:
  - pg_dump if your back end database is PostgreSQL, or
  - sqlcmd with an appropriate command for differential backup, if your back end database is MS SQL Server,
- use the optimal file system backup tool for your Stash home directory, for example:
  - an LVM snapshot logical volume if your Stash home directory uses LVM,
  - a SAN-based backup if your Stash home directory uses a Storage Area Network, or
  - rsync, if available.
The use of optimal, vendor-specific database and file system backup tools is the key to reducing Stash downtime to a minimum.

Stash DIY Backup does require you to write some code in a language of your choice to perform the required backup steps, using the REST API available for Stash 2.12.

DIY Backup supports Windows and Linux platforms, and Stash versions 2.12 and higher.

For information about other backup strategies for Stash, see Data recovery and backups. That page also discusses the tight coupling between the Stash file system on disk and the database that Stash uses.

Please note that the examples on this page are provided as guidance for developing a DIY Backup solution. As such, the third-party tools described are for example only – you will need to choose the tools that are appropriate to your own specific installation of Stash.

Consult the vendor documentation for the third-party tools you choose – unfortunately, Atlassian can not provide support for those tools.

This page:
- Describes a complete DIY Backup solution for a PostgreSQL database and local filesystem, using bash shell scripts.
- Provides background information about how the Stash REST API can be used for DIY Backups.

You can use this solution directly if your Stash instance has the same or similar configuration, or use this as a starting point to develop your own DIY Backup solution tailored to your hardware configuration.

How it works

When you use DIY Backup instead of the Stash Backup Client, you have complete control over the backup steps, and can implement any custom processes you like in the language of your choice. For example, you can use your database's incremental or fast snapshot tools and/or your file server's specific tools as part of a DIY Backup.

The DIY Backup works in a similar way to the Stash Backup Client and does the following:

1. Prepare the instance for backup. This happens before Stash is locked, so we want to do as much processing as possible here in order to minimize downtime later. For example, we can take an initial snapshot using incremental database and filesystem utilities. These do not have to be 100% consistent as Stash is still running and modifying the database and filesystem. But taking the initial
snapshot now may reduce the amount of work done later (while Stash is locked), especially if the amount of data modified between backups is large. The steps include:

- Taking an initial backup of the database (if it supports progressive/differential backups).
- Doing an initial rsync of the home folder to the backup folder.

2. Tell Stash to initiate the backup. Stash will:

- Lock the instance.
- Drain and latch the connections to the database and the filesystem.
- Wait for the drain/latch step to complete.

3. Once the Stash instance is ready for backup we can start with the actual DIY Backup. This will include steps to:

- Make a fully consistent backup of the database, using pg_dump.
- Make a fully consistent backup of the filesystem, using rsync.

4. Notify the Stash instance once the backup process finishes and unlock it.

5. Archive all files created during the backup into one big archive.

A user will get an error message if they try to access the Stash web interface, or use the Stash hosting services, when Stash is in maintenance mode.

As an indication of the unavailability time that can be expected, in our testing and internal use we have seen downtimes for Stash of 7–8 minutes with repositories totalling 6 GB in size when using the Stash Backup Client. For comparison, using Stash DIY Backup for the same repositories typically results in a downtime of less than a minute.

What is backed up

DIY Backup backs up all the same data as the Stash Backup Client:

- the database Stash is connected to (either the internal or external DB)
- managed Git repositories
- the Stash logs
- installed plugins and their data

DIY Backups using Bash scripts

This section presents a complete DIY Backup solution that uses the following tools:

- bash - for scripting
- jq - an open source command line JSON processor for parsing the REST responses from Stash
- pg_dump (or sqlcmd) - for backing up a PostgreSQL database
- rsync - for backing up the filesystem
- tar - for making a backup archive

This approach (with small modifications) can be used for running DIY Backups on:

- Linux and Unix
- OSX
- Windows with cygwin (note that cygwin Git is not supported by Stash).

Download the scripts from Bitbucket.

Bash scripts

These scripts implement one particular solution for performing a DIY Backup:

```

Running the Bash script

Once you have downloaded the Bash scripts, you need to customize two files:

- stash.diy-backup.vars.sh
- stash.diy-backup.sh

for your setup.

For example, if your Stash server is called `stash.example.com`, uses port 7990, and has its home directory in `/stash-home`, here's how you might configure `stash.diy-backup.vars.sh`:

```bash
#!/bin/bash

# Used by the scripts for verbose logging. If not true only errors will be shown.
STASH_VERBOSE_BACKUP=TRUE

# The base url used to access this Stash instance.
STASH_URL= http://stash.example.com:7990

# The username and password for the account used to make backups (and has permission for this).
STASH_BACKUP_USER= admin
STASH_BACKUP_PASS= admin

# The name of the database used by this instance.
STASH_DB= stash

# The path to Stash home folder (with trailing /).
STASH_HOME= /stash-home

# The path to the working folder for the backup.
STASH_BACKUP_ROOT= /stash-backup
STASH_BACKUP_DB=${STASH_BACKUP_ROOT}/stash-db/
STASH_BACKUP_HOME=${STASH_BACKUP_ROOT}/stash-home/

# The path to where the backup archives are stored.
STASH_BACKUP_ARCHIVE_ROOT= /stash-backup-archives
```

The supplied `stash.diy-backup.vars.sh` is written to use PostgreSQL, rsync, and tar by default. But if you want to use different tools, you can also customize the top section of this file to use different tools as follows:
Example usage:

```bash
# The following scripts contain functions which are dependant on the
# configuration of this Stash instance.
# Generally, each of them exports certain functions, which can be
# implemented in different ways.

# Exports the following functions:
# stash_prepare_db - for making a backup of the DB if differential
# backups are possible. Can be empty.
# stash_backup_db - for making a backup of the Stash DB.
source ${SCRIPT_DIR}/stash.diy-backup.postgresql.sh

# Exports the following functions:
# stash_prepare_home - for
# preparing the filesystem for the backup.
# stash_backup_home - for
# making the actual filesystem backup.
source ${SCRIPT_DIR}/stash.diy-backup.rsync.sh

# Exports the following functions:
# stash_backup_archive - for archiving the backup folder and moving
# the archive to the archive folder.
source ${SCRIPT_DIR}/stash.diy-backup.tar.sh
```

You also need to create two directories for DIY Backup to work:

1. `$(STASH_BACKUP_ROOT)` is a working directory (/stash-backup in our example) where copies of Stash’s home directory and database dump are built during the DIY Backup process.
2. `$(STASH_BACKUP_ARCHIVE_ROOT)` is the directory (/stash-backup-archives in our example) where the final backup archives are saved.

Once your stash.diy-backup.vars.sh is correctly configured, run the backup in a terminal window:

```
$ ./stash.diy-backup.sh
```

The first time you run the backup, rsync will do most of the work since the /stash-backup working directory is initially empty. This is normal. Fortunately, this script performs one rsync before locking Stash, followed by a second rsync while Stash is locked. This minimizes downtime.

On second and subsequent backup runs, /stash-backup is already populated so the backup process should be faster. The output you can expect to see looks something like this:
1. Restoring a DIY Backup

When restoring Stash, you must run the `stash.diy-restore.sh` script on the machine that Stash should be restored to. In order to ensure accidental restores do not delete existing data, you should never restore into an existing home directory.

The new database should be configured following the instructions in Connecting Stash to an external database and its sub-page that corresponds to your database type.

To see the available backups in your `$(STASH_BACKUP_ARCHIVE_ROOT)` directory, just type:

```bash
$ ./stash.diy-restore.sh
```

You should see output similar to this:

```
$ ./stash.diy-restore.sh
Usage: ./stash.diy-restore.sh <backup file name>.tar.gz
Available backups:
stash-20140320-092743-063.tar.gz stash-20140320-092843-063.tar.gz
```

To restore a backup, run `stash.diy-restore.sh` with the file name as the argument:

```bash
$ ./stash.diy-restore.sh stash-20140320-092743-063.tar.gz
```

You should see output like this:

```
$ ./stash.diy-restore.sh stash-20140320-092743-063.tar.gz
INFO: Performed restore of /stash-backup/stash-db/ to DB stash
```

Cancelling the backup

You can cancel the running backup operation if necessary.

To cancel the backup:

1. Copy the cancel token echoed in the terminal (or the Command Prompt on Windows):
1. Go to the Stash interface in your browser. Stash will display this screen:

![Performing Backup](image)

**Performing Backup**

Backup is currently underway and shouldn't take long.

- Backing up Stash data
- Cancel backup

2. Click **Cancel backup**, and enter the cancel token:

Advanced - writing your own DIY Backup using the REST APIs

This section is optional and provides background information about how you might use the Stash REST APIs if you need to rewrite the DIY Backup scripts described above in your preferred language or to customize them heavily.

Note that this discussion shows **curl** commands in Bash, however you can use any language.

The following steps are involved:

**Preparation**

Before you lock Stash you can perform any preparation you like. It makes sense to perform as much processing as possible before you lock Stash, to minimize downtime later. For example, you could perform...
an rsync:

rsync -avh --delete --delete-excluded --exclude=/caches/ --exclude=/data/db.* --exclude=/export/ --exclude=/log/ --exclude=/plugins/.*/ --exclude=/tmp --exclude=./.lock ${STASH_HOME} ${STASH_BACKUP_HOME}

Lock the Stash instance

The next step in making a backup of a Stash instance is to lock the instance for maintenance. This can be done using a POST request to the /mvc/maintenance/lock REST point (where STASH_URL points to the Stash instance, STASH_BACKUP_USER is a Stash user with backup permissions, and STASH_BACKUP_PASS is this user’s password).

If successful, the Stash instance will respond with a 202 and will return a response JSON similar to the one above. The unlockToken should be used in all subsequent requests where $STASH_LOCK_TOKEN is required. This token can also be used to manually unlock this Stash instance.

Start the backup process

Next, all connections to both the database and the filesystem must be drained and latched. When backing up the database, we have two options:

- Use the facilities provided by the Stash server – your code handles backing up of the filesystem and Stash backs up the database.
- Do a completely custom back up of the database – your code must handle backing up of both the filesystem and the database.

Both options make a POST request to /mvc/admin/backups but if we require a custom database backup (the second option) we need to add the ?external=true parameter (requires Stash 2.12+):
If successful the Stash instance will respond with 202 and a response JSON similar to the one above will be returned. The `cancelToken` can be used to manually cancel the backup process.

If you use Stash to back up your database (i.e., you `POST` to `/mvc/admin/backups` without the `?external=true` parameter), Stash will save the complete database backup (in a vendor independent format) to a file name of the form

```
${STASH_HOME}/export/backup-admin-20140325-223629-897Z.zip
```

Your backup process must include this file in the final archive.

**Wait for the Stash instance to complete preparation**

Part of the backup process, even if Stash is doing a database backup, includes draining and latching the connections to the database and the filesystem. Before continuing with the backup process we have to wait for the Stash instance to report that this has been done. To get details on the current status we make a `GET` request to the `/mvc/maintenance` REST point.
This causes the Stash instance to report its current state. We have to wait for both `db-state` and `scm-state` to have a status of `DRAINED` before continuing with the back up.

**Perform the actual backup**

At this point we are ready to create the actual backup of the Stash filesystem. For example, you could use `rsync` again:

```
rsync -avh --delete --delete-excluded --exclude=/caches/ --exclude=/data/db.* --exclude=/export/ --exclude=/log/ --exclude=/plugins/.*/ --exclude=/tmp --exclude=/.lock ${STASH_HOME} ${STASH_BACKUP_HOME}
```

The `rsync` options shown here are for example only, but indicate how you can include only the required files in the backup process and exclude others. Consult the documentation for `rsync`, or the tool of your choice, for a more detailed description.

When creating the database backup you could use your vendor-specific database backup tool, for example `pg_dump` if you use PostgreSQL:

```
pg_dump -Fd ${STASH_DB} -j 5 --no-synchronized-snapsots -f ${STASH_BACKUP_DB}
```

While performing these operations, good practice is to update the Stash instance with progress on the backup so that it's visible in the UI. This can be done by issuing a `POST` request to `/mvc/admin/backups/progress/client` with the token and the percentage completed as parameters:
The Stash instance will respond to this request with an empty 202 if everything is OK.

The amount of progress that Stash displays to users is calculated differently, depending on whether you used the external=true parameter with the /mvc/admin/backups REST endpoint described in the section above.

- If you did not specify external=true, Stash backs up the database and divides the 100 per cent progress into 50% user DIY Backup, and 50% Stash (preparation + database).
- If you did specify external=true, your code must handle backing up of both the filesystem and the database, and Stash divides the 100 per cent progress into 90% user DIY Backup, and 10% Stash preparation.

Inform the Stash instance that the backup is complete

Once we've finished the backup process we must report to the Stash instance that progress has reached 100 percent. This is done using a similar request to the progress request. We issue a POST request to /mvc/admin/backups/progress/client with the token and 100 as the percentage:

```bash
curl -s -u ${STASH_BACKUP_USER}:${STASH_BACKUP_PASS} \
-X POST \
-H "Accept: application/json" \
-H "Content-type: application/json"
"${STASH_URL}/mvc/admin/backups/progress/client?token=${STASH_LOCK_TOKEN}&percent\nage=100"
```

The Stash will respond with an empty 202 if everything is OK. The back up process is considered completed once the percentage is 100. This will unlatch the database and the filesystem for this Stash instance.

Unlock the Stash instance

The final step we need to do in the back up process is to unlock the Stash instance. This is done with a DELETE request to the /mvc/maintenance/lock REST point:

```bash
curl -s -u ${STASH_BACKUP_USER}:${STASH_BACKUP_PASS} \
-X DELETE \
-H "Accept: application/json" \
-H "Content-type: application/json"
"${STASH_URL}/mvc/maintenance/lock?token=${STASH_LOCK_TOKEN}"
```
The Stash instance will respond to this request with an empty 202 if everything is OK, and will unlock access.

**High availability for Stash**

If Stash is a critical part of your development workflow, maximizing application availability becomes an important consideration. This guide aims at providing the background information you need to be able to set up Stash in a highly available configuration. There are however many possible configurations for setting up a HA environment for Stash, depending on the infrastructure components and software (SAN, clustered databases, etc.) you have at your disposal. This guide aims at providing a high-level overview and describes a possible configuration in more detail.

Please note that your feedback and comments are welcome! We very much value additional lessons learned from your experience with alternative scenarios!

**High availability**

*High availability* describes a set of practices aimed at delivering a specific level of "availability" by eliminating and/or mitigating failure via redundancy. Failure can result from unscheduled down-time due to network errors, hardware failures or application failures, but can also result from failed application upgrades. Practices for achieving high availability range from organizational concerns such as change management to automated failover procedures when system failures are detected. Setting up a highly available system involves:

- **Proactive Concerns**
  - Change Management (including Staging / Production instances for change implementation)
  - Create redundancy of network, application, storage and databases
  - Monitoring system(s) for both the network and applications
- **Reactive Concerns**
  - Technical Failover mechanism, either automatic or scripted semi-automatic with manual switchover
  - Standard Operating Procedure for guided actions during crisis situations
This guide assumes that processes such as change management are covered and will focus on redundancy / replication and failover procedures. When it comes to setting up your infrastructure to quickly recover from system or application failure, you have different options. These options vary in the level of uptime they can provide. In general, as the required uptime increases, the complexity of the infrastructure and the knowledge required to administer the environment increases as well (and by extension the cost goes up as well).

**Understanding the availability requirements for Stash**

Central version control systems such as Subversion, CVS, ClearCase and many others require the central server to be available for any operation that involves the version control system. Committing code, fetching the latest changes from the repository, switching branches or retrieving a diff all require access to the central version control system. If that server goes down, developers are severely limited in what they can do. They can continue coding until they're ready to commit, but then they're blocked.

Git is a distributed version control system and developers have a full clone of the repository on their machines. As a result, most operations that involve the version control system don't require access to the central repository. When Stash is unavailable developers are not blocked to the same extent as with a central version control system.

As a result, the availability requirements for Stash may be less strict than the requirements for say Subversion.

• On failure, all requests are routed to the 'standby' server, which becomes 'active'
• ❌ This configuration is currently not supported by Stash, because Stash uses in-memory caches and locking mechanisms. At this time, Stash only supports a single application instance writing to the Stash home directory at a time. |

**Automatic correction**
Before implementing failover solutions for your Stash instance consider evaluating and leveraging automatic correction measures. These can be implemented through a monitoring service that watches your application and performs scripts to start, stop, kill or restart services.

1. A Monitoring Service detects that the system has failed.
2. A correction script attempts to gracefully shut down the failed system.
   a. If the system does not properly shut down after a defined period of time, the correction script kills the process.
3. After it is confirmed that the process is not running anymore, it is started again.
4. If this restart solved the failure, the mechanism ends.
   a. If the correction attempts are not or only partially successful a failover mechanism should be triggered, if one was implemented.

Cold standby

The cold standby (also called Active/Passive) configuration consists of two identical Stash servers, where only one server is ever running at a time. The Stash home directory on each of the servers is either a shared (and preferably highly available) network file system or is replicated from the active to the standby Stash server.

When a system failure is detected, Stash is restarted on the active server. If the system failure persists, a failover mechanism is started that shuts down Stash on the active server and starts Stash on the standby server, which is promoted to ‘active’. At this time, all requests should be routed to the newly active server.

For each component in the chain of high availability measures, there are various implementation alternatives. Although Atlassian does not recommend any particular technology or product, this guide gives examples and options for each step. In the following, each component in the system is described and an example configuration is used to illustrate the descriptions.

</tbody>

### Stash server

Each server hosts an identical Stash installation (identical versions).

Only one server is ever running a Stash instance at any one time (known as the active server). All others are considered as standbys.

The Stash home directory resides on a replicated or shared file system visible to all application servers (described in more detail below).

The Stash home directory must never be modified when the server is in standby mode.

### Stash DB

The production database, which should be highly available. How this is achieved is not explored in this document. See the following database vendor-specific information on the HA options available to you:

<table>
<thead>

</tbody>
</table>

### Example HA implementation

This particular implementation is provided to illustrate the concepts, but hasn’t been tested in production. We strongly recommend that you devise a solution that best fits your organisation’s existing best practices and standards and is thoroughly tested for production readiness.

The example configuration that we'll use to illustrate the concepts consists of a Linux cluster of two nodes. Each node is a CentOS server with Java, Git and Stash installed. Stash’s home directory is replicated between the nodes using DRBD, a block-level disk replication mechanism. The cluster is managed by DRBD, a high availability resource manager, is used to manage two HA resources: Stash and a Virtual IP. Pacemaker runs on each machine, elects the ‘primary’ node for Stash and starts Stash on this node. The Virtual IP resource is configured to run on the same node as the Stash resource, removing the need for a separate ‘request router’ component. Pacemaker monitors Stash and when it detects a failure tries to restart Stash on the primary node. If the restart fails, or does not resolve the issues, it fails over to the secondary node. The Virtual IP resource is configured to run on the same node as the Stash resource and will also be moved to the secondary node.

Scripts to create a virtual network based on this example configuration using packer, vagrant and VirtualBox can be found in the stash-ha-example repository. Specifically, the scripts for installing the required software components can be found in the packer/scripts directory. The scripts for configuring the cluster can be found in the vagrant/scripts directory.
Request router

All high availability solutions are based on redundancy, monitoring and failover. In the cold standby approach, only one server is running Stash at a time. It is the request router's responsibility to route all incoming requests to the node that is currently the primary node. For full high availability, the request router should be highly available itself, meaning that the component is monitored by the HA manager and can be failed over to a redundant copy in the network.

Requirements

- Routes all incoming requests to the node that is currently the 'primary' node
- Should be highly available itself

Options

- HAproxy
- Keepalived
- LVS
- LinuxHA
- various commercial solutions

Solution in example HA implementation

The example HA implementation does not include a separate Request Router server. Instead it includes a virtual IP HA resource that is co-located with the Stash resource. The virtual IP resource is managed by Pacemaker and will be moved to the standby node when the Stash resource fails over to the standby node.

Data replication

Stash stores its data in two places: the Stash home directory and the database that you have configured. The Stash home directory contains, among other things, the Git repositories being managed by Stash (with some additional Stash-specific files and directories), installed plugins, caches and log files. The database contains, among other things, your project and repository information and metadata, pull requests data and the data for your installed plugins.

Data in Stash's home directory and in the database are very tightly coupled. For instance, repository pull requests have their metadata, participants and comments stored in the database but certain Git-oriented information around merging and conflicts (which are used to display the diffs in the user interface) are stored in the managed Git repositories. If the two were to fall out of sync you might see an incorrect pull request diff, you might be left unable to merge the pull request, or Stash may simply refuse to display the pull request at all. Similarly, Stash plugins are installed from jar files in the Stash home directory but their state is stored in the database. If the two were to fall out of sync then plugins may malfunction or not appear installed at all, thus degrading your Stash experience.

When designing a high availability solution for Stash based on a replicated file system and database, it's important that the file system replication is atomic. The replicated file system must be a consistent snapshot of the 'active' filesystem. This is important because changes to a Git repository happen in predictable ways: first the objects (files, trees and commits) are written to disk, followed by updates of the refs (branches and tags). Some
synchronisation tools such as rsync perform file-by-file syncing, which can result in an inconsistent Git repository if the repository is modified while the sync is happening (for example, if object files have not been synced, but the updated refs have been).

Furthermore, the tight coupling between the Stash home directory and database makes it essential that the Stash home directory and database are always consistent and in sync (see here for more information). By extension, this means that any high availability solution based on a replicated file system and database needs to ensure that the replicated file system and database are in sync. For example, if the replication is based on hourly synchronisation to a standby node, care must be taken to ensure that the synchronisation of the database and filesystem happen at the same time.

Requirements

- File system replication must replicate a consistent snapshot of Stash's home directory.
- The database and the file system must be replicated at the same time.

Options

- DRBD
- LVM
- SAN
- NAS
- various commercial solutions

Solution in example HA implementation

The example HA implementation uses a DRBD managed block device for its Stash home directory. By default, DRBD runs in a Primary/Secondary configuration in which only a single node can mount the DRBD managed volume at a time. In this configuration, DRBD should be managed by Pacemaker to ensure that the DRBD volume is co-located with the Stash resource.

In preparation for experimentation with an Active/Active configuration, the example HA implementation has configured DRBD in a dual-primary configuration, which allows both nodes to mount the DRBD managed volume at the same time.

Monitoring

To allow for monitoring in a high availability environment, Stash, since version 2.10, has supported a REST-based health check endpoint at /status that describes the current health of the instance. This endpoint supports only the GET verb and requires no authentication, XSRF protection header values, or mime-type headers. The /status endpoint has been designed to return sane output even when Stash is currently unavailable as a result of database migration or backup. Please note that other URLs such as /login or /rest/api/latest/application-properties will redirect to the maintenance page when Stash is performing database migration or backup. Using these endpoints may unintentionally trigger failover when these URLs are used for monitoring the health of the system.

Example usage:

```bash
> curl -i -u user -X GET http://localhost:7990/stash/status
Enter host password for user 'user':
HTTP/1.1 200 OK
Server: Apache-Coyote/1.1
X-AREQUESTID: 1040x7x0
X-XSS-Protection: 1; mode=block
X-Frame-Options: SAMEORIGIN
X-Content-Type-Options: nosniff
Content-Type: application/json;charset=ISO-8859-1
Content-Length: 19
Date: Tue, 07 Jan 2014 17:20:04 GMT
{"state":"RUNNING"}
```

The following is a list of the responses the /status health check endpoint will return:
### Monitoring frequency

Stash’s health check is simple and not resource intensive. You should feel free to check as often as is deemed necessary to maximise continuity of Stash in your organisation. We do recommend, however, to not check more frequently than every 15 seconds so that the HA resource manager / cluster does not mistake transitory slowdowns such as stop-the-world garbage collection in Stash’s JVM. We recommend a monitor timeout of 30 seconds because the first check after startup can be fairly slow. After startup completes, the check should take only a few milliseconds.

### Requirements

- Monitoring scripts must use the `/status` URL. Any other URL may redirect to the maintenance page when a backup is being performed, unintentionally triggering failover.
- When a request to `/status` returns anything other than a 200 status code, Stash should be considered to be in an error state and should be failed over the standby node.

### Solution in example HA implementation

The example HA implementation includes an OCF compliant script that’s used for monitoring Stash’s health. The script can be found here.

### Failover

The following table outlines how we recommend that your HA resource manager responds to failure events:

<table>
<thead>
<tr>
<th>Event</th>
<th>Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>Network connection from the request router to Stash is lost</td>
<td>Failover to a secondary node</td>
</tr>
<tr>
<td>Server failure</td>
<td>Failover to a secondary node</td>
</tr>
<tr>
<td>Stash crashes completely</td>
<td>Restart Stash on the active node</td>
</tr>
<tr>
<td>Stash reaches its memory limits (OOME)</td>
<td>Restart Stash on the active node</td>
</tr>
<tr>
<td>Stash loses connection to the database</td>
<td>Nothing. Stash will recover when the database comes back on line. Stash on another node will also fail to start if the database is unavailable.</td>
</tr>
</tbody>
</table>
The database is reported down

| Nothing. Stash will recover when the database recovers. Stash on another node will also fail to start. |

Stash fails to start up (e.g. wrong Git binary version)

| Nothing. Manual intervention required. Stash on another node will also fail to start. |

**Split brain**

A split-brain condition results when a cluster of nodes encounters a network partition and multiple nodes believe the others are dead and proceed to take over the cluster resources. In the context of a Stash HA installation this would involve multiple Stash instances running concurrently and making filesystem and database changes, potentially causing the filesystem and database to fall out of sync. As previously noted this must not be permitted to happen. There are several ways to address this:

**Network redundancy**

This involves configuring redundant and independent communications paths between nodes in the cluster. If you maximise the connectivity between nodes you minimise the likelihood of a network partition and a split brain. This is a preventative measure but it is still sometimes possible for the network to partition.

**Resource fencing**

This involves ensuring that the first node that believes the others are dead 'fences off' access to the resource that other nodes (which appear dead but may still be alive) may try to access. The losing nodes are prevented from making modifications, therefore maintaining consistency. In a Stash HA, the resources that would need to be fenced are the database and the replicated file system.

**Node fencing or STONITH**

This is a more aggressive tactic and again involves the first node that believes the others are dead, but instead of fencing off access to particular resources, it denies all resource access to them. This is most commonly achieved by power-cycling the losing nodes (aka "Shoot The Other Node In The Head" or STONITH). In a Stash HA, this would involve power-cycling the losing Stash servers.

**Requirements**

- The application should fail over to a secondary node when a server failure is detected by the cluster manager (that is, the whole node is down or unreachable).
- When an application failure is detected, the application should be restarted. If restarting does not resolve the issue, the application should be failed over to a secondary node.

**Solution in example HA implementation**

The example implementation uses Pacemaker to manage failover. Pacemaker in turn uses the provided OCF script to properly shut down the failing Stash and start Stash on the secondary node.

Please note that the vagrant provisioning script in the example implementation contains a simplified configuration that is aimed at testing failover. It configures Stash to immediately failover to a secondary node, without attempting to restart the application. It also disables the STONITH feature for ease of testing. In a production system, at least one restart should be attempted before failing over and STONITH should be enabled to handle 'split brain' occurrences.

**Lockout recovery process**

This page describes how to recover administrator access to Stash when, as an administrator, you find yourself locked out of Stash and unable to log in. This situation can arise when all users are managed externally from Stash, and Stash becomes unable to access those user directories for some reason, including:

- The external user directory server is not accessible (because the network is down, or the directory is down, or the directory has been moved to another IP address)
- Users are managed in JIRA and the Application Link from Stash to JIRA has been accidentally deleted
- The admin password has been forgotten or lost
The admin account is shaded by a remote account in an LDAP or JIRA instance that is connected to Stash but which is unavailable.

The lockout recovery process for Stash is:

1. **Edit** the `<Stash installation directory>/bin/setenv.sh` file (or `setenv.bat` on Windows) and add the `-Datlassian.recovery.password=temporarypassword` argument to the `JVM_SUPPORT_RECOMMENDED_ARGS` property. The property value must be non-blank, and should look like this when you've done that:

   ```
   # Occasionally Atlassian Support may recommend that you set some specific JVM arguments. You can use this variable below to do that.
   # JVM_SUPPORT_RECOMMENDED_ARGS="-Datlassian.recovery.password=temporarypassword"
   ```

   Here we are using "temporarypassword", but you can use your own value.

2. Start Stash.
3. Log in to Stash using the 'recovery_admin' username and the temporary password specified in Step 1.
4. Repair your Stash configuration. We strongly recommend that you do not perform other actions while Stash is in recovery mode.
5. Confirm your ability to log in with your usual admin profile.
6. Shut down Stash, remove the `atlassian.recovery.password` argument from `setenv.sh`, and restart Stash as usual.

**Stash 2.12**

25 March 2014
- Custom avatar images
- User name linking to profile page
- Read/write access keys
- Access key bulk revocation
- Diff hunk map
- DIY Backup
- Comment display toggling
- Markdown rendering in the Source view
- Markdown table syntax in comments

Stash 2.10

17 December 2013

Small improvements:

- **Branch Utils REST API**
  - The SSH clone URL is now shown for admins who don't have a user key, when a project or repository access key is available
  - The permission screens for projects and repositories have been tidied
  - Log files in Stash now use UTF-8 encoding when you start Stash from IDEA or Maven
  - The URL now updates correctly when you switch revisions via the file history, when viewing the ‘Diff to previous’ tab for a repo
  - Stash has been updated to use AUI 5.3
  - Atlassian platform upgrade for 2.10

Read the Stash 2.10 release notes and change log.

Stash 2.9

19 November 2013

- Branch listing improvements
- SSH access keys for projects and repositories
- Pull request inbox – my pull requests
- Build status during branch creation
- Support for PostgreSQL 9.3
- Extra keyboard shortcuts
- Extra merge strategy option
- Support for changing usernames

Stash 1.0 is released!

1st May 2012
Atlassian Stash is a repository management solution that allows everyone in your organisation to easily collaborate on all your Git repositories.

In Stash you can:
• Create Git repositories and organize them into projects
• Browse your repositories and your commits
• View the changesets, diffs, blame and history of your files
• Create new users and organize them into groups
• Manage permissions at a global and at a project level
• Integrate with JIRA

Read the Stash 1.0 release notes.

See the change log for Stash 1.0.x minor releases.

Stash upgrade guide

This page describes how to upgrade Stash from a previous version.

• For the latest and greatest Stash release, see Releases.

For production environments we recommend that you test the Stash upgrade on a QA server before deploying to production.

Please also read:
• the Supported platforms page for the full list of supported platforms for Stash.
• the End of support announcements for Stash.
• the Integrating Stash with Atlassian applications page for version compatibility information.

On this page:
• Upgrade steps
• Upgrading to Stash 2.12
• Upgrading to Stash 2.11
• Upgrading to Stash 2.10
• Upgrading to Stash 2.9
• Upgrading to Stash 2.8
• Upgrading to Stash 2.7
• Upgrading to Stash 2.6
Upgrading steps

This section provides general instructions for upgrading Stash. See also the specific notes on this page for the version of Stash you are upgrading to. We strongly recommend that you upgrade Stash by following these steps:

1. Stop Stash!

To stop Stash, change directory in a terminal or command prompt to the `<Stash installation directory>` and run:

   - **Windows:**
     ```
     bin\stop-stash.bat
     ```
   - **Linux and Mac:**
     ```
     bin/stop-stash.sh
     ```

2. Back up your Stash data!

Back up the Stash home directory. This is where your Stash data is stored. The home directory location is defined:

   - On Windows: by the `STASH_HOME` environment variable, or by the `STASH_HOME` line of `<Stash installation directory>/bin/setenv.bat`.
   - On Linux and Mac: by the `STASH_HOME` line of `<Stash installation directory>/bin/setenv.sh`.

If you are using an external database, back up this database. Follow the directions provided by the database vendor to do this.

See Data recovery and backups for more information.

3. Download and install Stash as usual

   **Download Stash** from the Atlassian download site and unpack the archive file to a suitable location.

   - Note that you should not simply copy the unpacked Stash directory over an existing Stash directory. Copying a new Stash directory over the existing one is not supported – that will always corrupt the system. This is because each version of Stash includes versioned jar files, such as `stash-model-2.4.1.jar`. If you copy these, you end up with multiple versions of Stash's jar files in the classpath, which leads to runtime corruption.

   Update the value of `STASH_HOME` in the new Stash installation directory to point to your existing Stash home directory (but note that if you use a `STASH_HOME` environment variable to specify the home directory location then no change is required):

   - On Windows, update the home directory location as defined by the `STASH_HOME` line of the new `<Stash installation directory>/bin/setenv.bat`. 

Created in 2014 by Atlassian. Licensed under a Creative Commons Attribution 2.5 Australia License.
To start Stash, change directory in a terminal or command prompt to the `<Stash installation directory>` and run:

- Windows:
  ```
  bin\start-stash.bat
  ```

- Linux and Mac:
  ```
  bin/start-stash.sh
  ```

Note that the database schema migration task that runs when Stash is started after an upgrade can take a while, especially if the upgrade has skipped a few releases (for example, upgrading from Stash 2.2 to 2.7). Stash should never be interrupted while this is happening, even if Stash appears to have hung – allow the server to either come up, or fail to come up (when it will provide an explanation of what went wrong).

5. Rollback

If necessary, rolling back an upgrade should only be performed by restoring a backup of both the Stash home directory and the Stash database – rolling back requires a consistent home directory and database. You can then reinstall the previous version of Stash to the `<Stash installation directory>`.

Upgrading to Stash 2.12

Please also see:

- the Upgrade steps section above.
- the End of support announcements for Stash. In particular, note that support for Java 6 is deprecated. Stash 3.0+ will require Java 7.
- the Stash 2.12 release notes.

Note that:

- Stash does not yet support Java 8.
- Stash 2.12 does not support Git 1.8.4.3
- Stash does not support the Apache HTTP Server mod_auth_basic module.

Note that Stash does not support Git 1.8.4.3. See Supported platforms.

Pull Request Ref Optimization

When you first start Stash after upgrading to Stash 2.9 a repository upgrade task runs that optimizes the pull request refs for all repositories managed by Stash. It's important that you do not interrupt this upgrade process. You can track the progress of this in the Stash logs. See STASH-3469 - Pull request references in the Git repository are never removed after merge or decline.

Backup Client Upgrade Required

Version 1.0.3 of the Stash Backup Client is required to back up Stash 2.9.

Repository System Information Plugin is now deprecated

The functionality of the repository system information plugin has now been moved into core Stash. The plugin will still work for Stash 2.x versions but is redundant as of Stash 2.7.

MySQL default isolation level

Stash 2.7.x uses READ_COMMITTED instead of the MySQL default isolation level (REPEATABLE_READ). This can result in exceptions when installing or upgrading to 2.7.x, if binary logging is enabled in your MySQL server. More details and a fix can be found in this KB article.

Install location for third-party libraries

As of Stash 2.1 you can install third-party libraries and jar files, such as the MySQL JDBC driver, into `<Stash home directory>/lib`. This has the advantage that files in this location are not overwritten, and lost, when you upgrade Stash.

Microsoft SQL Server JDBC driver

Stash 2.1 now uses the Microsoft SQL Server JDBC driver to access Microsoft SQL Server, instead of using the jTDS driver. In most cases, Stash will automatically swap to using the Microsoft driver on upgrade and no configuration is required.

If Stash was configured to use Microsoft SQL Server by manually entering a JDBC URL, please refer to this guide.

Upgrading to Stash 2.0

This section provides specific notes for upgrading to Stash 2.0. See also the Upgrade steps section above.

Tomcat

For Stash 2.0, Tomcat has been upgraded from version 6 to 7. As part of that upgrade, the server.xml file has changed. If you have customised server.xml (for example, for port, path or hostname), you can not simply copy your own version across to the upgraded Stash; you must reapply your customisations to the server.xml file for the new version of Stash.

If you were running Stash as a Windows service and are upgrading from 1.x to 2.x you will need to reinstall the Stash service to make it use Tomcat 7.

To uninstall the Stash service you need to execute following commands from `<STASH DISTRIBUTION DIR>/bin:

```
> net stop <service name>
> service.bat uninstall <service name>
```

You can call this command without the service name if you installed the Stash service with a default name.

After the service is uninstalled you can proceed with the Upgrade steps and Running Stash as a Windows service instructions to configure Stash 2.x running as a service.

Perl

Stash 2.0 requires Perl for its branch permission functionality. If Perl is unavailable, Stash 2.0 will not start.

On Windows machines, Perl will only have been installed by the Git installer if the correct install option was chosen at Step 4 of Installing Stash on Windows.

Existing Git hooks
In order to support Branch Permissions, Stash 2.0 moves existing hooks in the pre-receive and post-receive folders under `<STASH_HOME>/data/repositories/NNNN/hooks` (where NNN is the internal repository id) to `.../hooks/pre-receive.d/10_custom` or `.../hooks/post-receive.d/10_custom`. Consequently, custom hooks that use relative path names (e.g. `"./foo.sh"` or `"../dir/foo.sh"`) will be broken by the upgrade to Stash 2.0.

**Deprecation of Internet Explorer 8**

Support for Internet Explorer 8 is deprecated from the release of Stash 2.0. The official end-of-support date is yet to be determined. See Supported platforms for details.

### Upgrading to Stash 1.3

This section provides specific notes for upgrading to Stash 1.3. See also the Upgrade steps section above.

**Email server**

An email server must be configured in Stash so that email notifications for pull request events can be sent. Please see Setting up your mail server for details.

**Upgrading from Stash 1.3 beta**

Click to see information about upgrading from the beta...

Stash 1.3 uses improved commenting compared to the 1.3 beta. This means that when you upgrade from the beta to Stash 1.3:

- Pull request comments made in the beta against the diff will only appear in the activity, and not in the diff, in Stash 1.3. Future comments made on the same pull request in Stash 1.3 will behave as expected.
- Reviewers, participants and watchers were added after the beta was released. After you upgrade, existing pull requests will not have participants or watchers. You can add reviewers by editing the pull requests and any future commenters will be added as a participant and watcher to the pull request as you would expect.

SSH

When you restart Stash after upgrading to 1.1, Stash will automatically enable SSH access to your repositories, on the default port of 7999.

If you want to change the port, or are hosted behind a proxy or firewall, you may also need to change the SSH base URL so the clone URL's in Stash are correct. See the SSH admin instructions.

Developing for Stash

If you are a Stash plugin developer, please refer to our Stash developer documentation.

Checking for known issues and troubleshooting the Stash upgrade

If something is not working correctly after you have completed the steps above to upgrade your Stash installation, please check for known Stash issues and try troubleshooting your upgrade as described below:

- **Check for known issues.** Known issues can be seen in the STASH project on our issue tracker.
- **Stash Knowledge Base.** Sometimes we find out about a problem with the latest version of Stash after we have released the software. In such cases we publish information in the Stash Knowledge Base.
- **If you encounter a problem during the upgrade and cannot solve it, please create a support ticket and one of our support engineers will help you.**

**Why is Atlassian ending support for these platforms?**

Atlassian is committed to delivering improvements and bug fixes as fast as possible. We are also committed to providing world class support for all the platforms our customers run our software on. However, as new versions of databases, web browsers etc. are released, the cost of supporting multiple platforms grows exponentially, making it harder to provide the level of support our customers have come to expect.
to expect from us. Therefore, we no longer support platform versions marked as end-of-life by the vendor, or very old versions that are no longer widely used.

End of support announcements on this page (most recent announcements first):

- Deprecation of Internet Explorer 8 (announced 22 July 2013)
- Deprecation of Java 6 (announced 9 May 2013)

**Deprecation of Internet Explorer 8 (announced 22 July 2013)**

In version 3.0, Stash will no longer support Internet Explorer 8, and will only support Internet Explorer 9 and above. Stash 3.0 is now expected to be released mid-2014. See Supported platforms.

**Deprecation of Java 6 (announced 9 May 2013)**

In version 3.0, Stash will no longer support Java 6.0, and will only support Java 7.0 and above. Stash 3.0 is now expected to be released mid-2013. See Supported platforms.

**Stash 2.12 release notes**

25 March 2014

**Introducing Stash 2.12**

Today we’re very pleased to announce Stash 2.12, which brings custom avatars, hunk maps for side-by-side diffs, enhanced SSH access keys, a new REST API for backing up and restoring Stash, and improvements to markdown rendering.

If you are upgrading from an earlier version of Stash, please read the Stash upgrade guide.

Please also check the End of support announcements for Stash.

The Stash 2.12 changelog is at the bottom of this page.

**Custom avatar images**

You can now upload a custom avatar image to your profile, which will replace your Gravatar image wherever that is used in Stash. Do this on the Account settings tab in your personal profile.
User name linking

When you're logged in to Stash you'll notice that wherever commit author names are displayed (for example, on the commits list, and the blame view) they are now linked to the profile page of the author (if the author is also a Stash user). Authors are matched to Stash users via the author's email address, and the user's name in their Stash account is displayed instead of their author name.

Hunk maps

We've improved how you can use side-by-side diffs, first introduced with Stash 2.11.

Now we've added a 'hunk map' to side-by-side diffs, to make it easier for you to find where a file has been changed. Simply click on the hunk map in the left- or right-hand margin to scroll the view to that location:
Access keys

We’ve extended how you can use SSH keys to secure Git operations for Stash repositories.

Firstly, system SSH access keys, which allow you to secure the Git operations performed by other systems on Stash repositories, can now be either Read-only or Read / Write. Now you can use operations like `git push` or `git merge` if you want the other system to merge successful feature branch builds to the default branch in the Stash repository, or so that deployments can be tagged.

### Add public key

**Permission**
- Read
- Read / Write

**Key**

Furthermore, we’ve provided greater visibility into where access keys are being used in Stash. When you want to delete a key, you now see a list of the other places where the key is being used, and can delete the key from those places as well:
The keys displayed in the list depend on your permissions to see those projects and repositories.

Read more about SSH access keys for system use...

DIY Backup

We’ve added to the backup and restore strategies available for use with Stash.

The new Stash DIY Backup is an alternative to the Stash Backup Client, and provides a REST API that allows you to:

- significantly reduce the downtime needed to create a consistent backup,
- use the appropriate industry-standard tools to back up your Stash file system and external database back end,
- automate the Stash back up process.

As an indication of the downtime that can be expected when using Stash DIY Backup, in our testing and internal use we have seen Stash downtimes of 7–8 minutes with repositories totalling 6 GB in size when using the Backup Client, compared with downtimes of less than a minute when using the new DIY Backup with the same repositories.

Read more about a fully worked solution in Using Stash DIY Backup...
Small improvements

Toggle comment display

Use the Shift-C keyboard shortcut or the diff options menu to toggle comment display, either in a unified diff or a side-by-side diff. The icon in the left margin shows that comments are hidden:

```javascript
$('aui-page-header').show().append($('el').show());
```

9 +  // Add aui class to all content tables
10  $content.find('table').addClass('aui');
```

Markdown rendering in source view

Markdown files are now rendered in the source view. The output handles images, links (including relative links) and table syntax.

### Stash 2.11 release notes

25 February 2014

Introducing Stash 2.11
Today we're excited to announce Stash 2.11, which brings added support for code review workflows with side-by-side diffs and new ways to discuss code changes.

If you are upgrading from an earlier version of Stash, please read the Stash upgrade guide.

Please also check the End of support announcements for Stash.

The Stash 2.11 changelog is at the bottom of this page.

Commit comments

Now you can get immediate feedback on changes in a particular commit, even if they're not part of a pull request. Commit discussions allow you to request feedback early on in the development cycle – not only to ensure you are on the right path, but also to speed up subsequent pull requests because the bulk of the changes have already been reviewed. Commit comments also let developers point out general issues in code or discuss ideas for improving code quality in future work.

You can comment directly on a line of code right in the diff, just as you've been able to do with diffs in pull requests. Just hover over the line of code, click the icon at the left (arrowed below), and enter your comment; @mention another Stash user in the comment, to get their attention.

As the author of the commit, or when you make a comment, you're automatically made a watcher, and get notified when others comment. You can watch, or unwatch, the commit at any time, of course.

File comments for pull requests and commits

Until now you've only been able to comment on particular lines of code in files under discussion in pull requests. But what if you wanted to comment about the whole file, or about a file without text, such as an image? Now you can!
Whether you're looking at a pull request or a file in a commit, just click the header icon (arrowed below, or use the 'M' keyboard shortcut) to add a comment about the whole file. You can do this in both a unified diff or a side-by-side diff (also new in this release - see below).

As with general or in-line comments, file comments on a pull request appear in the activity stream, so it's easy for others to see, and you can @mention other Stash users to really get their attention.

**Side-by-side diffs**

We added a new side-by-side view for when you're looking at diffs in both pull requests and commits – we think you'll find that this really improves your experience of using Stash for code reviews, and for viewing code changes in general.

Toggle between the unified diff and side-by-side diff views using the menu arrowed below. The side-by-side view is not available for added or removed files.

For a pull request, the lefthand panel shows the code in the target branch and the righthand panel shows what the result of merging will be. For a commit, the lefthand panel shows the previous revision and the righthand panel show the current revision.

As mentioned above, file comments and per-line comments are both available for the side-by-side view.

**MySQL 5.6.16+ is now supported**

Stash now supports versions of MySQL 5.6 from MySQL 5.6.16 on. See Supported platforms.

Lockout recovery process
We've made some changes to help admins who accidentally lock themselves out of Stash. See Lockout recovery process.

Stash 2.10 release notes
17 December 2013

Introducing Stash 2.10

Today we’re pleased to announce Stash 2.10, which brings a wide range of small improvements. We’ve also added considerable polish to the Stash experience – these changes are listed in the 2.10.0 changelog at the bottom of this page.

If you are upgrading from an earlier version of Stash, please read the Stash upgrade guide.
Please also check the End of support announcements for Stash.

Small improvements

We’ve made the following notable improvements:

- There is now a Branch Utils REST API that provides REST resources for managing branches in Stash repositories.
- The SSH clone URL is now shown for admins, when a project or repository access key is available.
- The permission screens for projects and repositories have been tidied.
- The URL now updates correctly when you switch revisions via the file history when viewing the 'Diff to previous' tab.
- Stash has been updated to use AUI 5.3.

Stash 2.9 release notes
19 November 2013

Introducing Stash 2.9
Today we’re excited to announce Stash 2.9, which makes managing your branches, pull requests and access to repositories much easier.

If you are upgrading from an earlier version of Stash, please read the Stash upgrade guide.

Please also check the End of support announcements for Stash.

The Stash 2.9 changelog is at the bottom of this page.

Branch listing improvements

We’ve made the branches listing a much more useful overview of the state of your repository:

- The new Pull requests status helps you to track the review and merge work that still needs to be done.
- The Behind/Ahead column helps you identify work in progress as well as stale branches, and now you can choose the base branch for the comparison.
- The new search makes it easy to find branches when you have a ton of them. Even better, if you’re using the Stash branch model, you can filter by branch type simply by searching for the prefix – for example, search for “feature/” to see all your feature branches.
- As before, the Builds column allows you to see the build status of branches at a glance.
- The Actions menus have altered tasks, such as creating a pull request, and checking out the branch in Atlassian SourceTree.
- There are new navigation shortcuts – see them in Keyboard shortcuts under the Stash Help menu.

SSH access keys for projects and repositories

Stash now provides a simple way for other systems to perform read-only Git operations on repositories managed in Stash. This allows systems such as your build server to authenticate with Stash to checkout and test source code, without having to store user credentials on another system, and without requiring a specific user account.

These new access keys complement the personal account keys that have been available since Stash 1.1 – but they work for repositories rather than user accounts.
Pull request inbox

Our pull request inbox has always provided easy access to the pull requests that need your review. In Stash 2.9, we’ve improved the inbox so that it also shows your own open pull requests. Toggle between these two sets directly from your inbox, and keep track of all your open pull requests seamlessly.

Small improvements

Build status during branch creation

When you’re creating a new branch, Stash displays the current build status for the source branch – is the branch good enough to branch from? Read more about build status ...

Support for PostgreSQL 9.3

See Supported platforms.
Extra keyboard shortcuts

We’ve added new keyboard shortcuts to help you navigate around the branch listing screen quickly – choose **Keyboard shortcuts** from the Stash Help menu to see these. Read more about the **branch listing screen**.

Extra merge strategy option

We’ve added the `squash-ff-only` option. As with `squash`, it collapses all the incoming commits into a single commit directly to the target branch, never creating a merge, but it does so only if the source branch is fast-forward. If not, a `MergeException` will be thrown. See **Stash config properties**.

Support for changing usernames

You can **change the username** for a user account that is hosted in Stash’s internal user directory. If a user is renamed in your LDAP directory, Stash will pick that up in the next synchronisation, or when the user next logs in. All content and attributes associated with the original username will be automatically associated with the new username, including pull requests, comments and permissions. See the **Crowd 2.7 release notes**.

Change log

This section will contain information about the Stash 2.9 minor releases as they become available. These releases will be free to all customers with **active Stash software maintenance**.

If you are upgrading from an earlier version of Stash, please read the **Stash upgrade guide**.

Stash 2.8 release notes

1 October 2013

Introducing Stash 2.8 – Git branch workflows

Today we’re excited to announce Stash 2.8, which makes it easy for your team to use a branching workflow for your Git development process.

If you are upgrading from an earlier version of Stash, please read the Stash upgrade guide.

Please also check the End of support announcements for Stash.

The Stash 2.8 changelog is at the bottom of this page.

Stash branching model

Stash 2.8 introduces a 'branching model' that provides key advantages for streamlining your Git development workflow:

- Developers can make consistent naming decisions when creating branches in Stash, guided by the naming conventions specified in the branching model.
- Reduce the need for manual maintenance of release branches, because consistent branch naming allows Stash to automatically cascade merges to those branch types.

Branching model

<table>
<thead>
<tr>
<th>Development</th>

Branch prefixes

Use the prefixes below as part of your branch names to categorize them and take advantage of automatic branching workflows. Learn more

- Bugfix: bugfix/
  - Typically used for fixing bugs against a release branch
- Feature: feature/
  - Used for specific feature work. Typically, this branches from and merges back into the development branch
- Hotfix: hotfix/
  - Typically used to quickly fix the production branch
- Release: release/
  - Used for release tasks and long-term maintenance. Typically, this branches from the development branch and changes are merged back into the development branch
Read more about the new branching model in Stash.

**Branch creation from within Stash**

You can now create new branches in your Git repositories directly from the Stash web UI. When a branching model is configured, Stash guides you into making consistent choices for branch names:

![Branch creation interface](image)

Read more about creating branches in Stash.

**Branch creation from within JIRA and JIRA Agile**

As part of our push to provide tighter integration between Stash and JIRA, you can now start creating a branch from within a JIRA issue, whether you are in JIRA or JIRA Agile. This gives you a faster workflow from picking an issue to starting coding:

![JIRA interface](image)

Stash will suggest the branch type and branch name, based on the JIRA issue type and summary – you can change these, of course.

Your Admin needs to have set up linking with JIRA before you’ll see this. Read more about creating branches from JIRA.

**Automated merges**
When a branching model is configured in Stash that defines a 'release' branch for a repository, Stash can automatically merge changes to newer release branches. Cascading merges can reduce the manual maintenance for branches of that type.

Automated merging must be enabled for each repository, and is subject to a number of conditions. Stash applies an ordering algorithm, based on patterns in the branch names, to determine the 'newer' branches.

Read more about automatic branch merging in Stash.

### Branch listing pages

To complement branch workflows, Stash now provides an overview of all branches in a repository. The **Behind/Ahead** information shows by how many commits a branch has diverged from the default branch (for example, master) for the repository, and can help you to identify work in progress as well as stale branches. The **Actions** menus provide branch tasks such as viewing the branches source files, creating a pull request, creating a new branch, and checking out the branch in Atlassian SourceTree.

<table>

### Move Git repositories between Stash projects

You can now move a repository from one Stash project to another, if you have project administrator permissions for both projects.

To move a repository, go to **Settings > Repository details** for the repository you wish to move, and click **Move repository**:
Improved integration with Atlassian SourceTree

You've been able to clone a repository from Stash using Atlassian SourceTree for a while. Now there are more ways that you can use Stash and SourceTree together, to help you use Git faster and more easily. Choose Check out in SourceTree from the Actions menu when you are:

- Viewing files or commits in a repository:

  ```
<table>

</table>
  ```

- Viewing branches in a repository:
Small improvements

Stash backup client is now production-ready

The Stash backup client introduced with Stash 2.7.0 is now supported for use in production environments. See Data recovery and backups.

See the branches that a commit is visible on

When browsing a commit you can now see all the branches that the current commit is visible on. This makes it easier to determine if a particular change has been merged to the master branch, for example, or not:

SSH support in the SCM Cache Plugin

The SCM Cache Plugin now supports SSH. This allows your CI build server to securely access the Stash server over SSH. See Scaling Stash for Continuous Integration performance for configuration information.

Auto-expand directories with only one sub-directory

In the files listing for a repository, Stash will now automatically expand a directory that contains only one sub-directory. This can save time where there is a series of nested single directories – Stash will continue expanding directories until it finds two or more sub-directories.

Stash 2.7 release notes

20 August 2013

Introducing Stash 2.7

Today we’re pleased to announce Stash 2.7, which introduces a range of JIRA integration improvements, to help optimise your development workflows. We’ve also included a brand new Stash backup and restore solution.

If you are upgrading from an earlier version of Stash, please read the Stash upgrade guide.

Please also check the End of support announcements for Stash.

The Stash 2.7 changelog is at the bottom of this page.

Try it for FREE ➔

JIRA issue transitions

Now you can easily transition a JIRA issue from within Stash. For example, when creating a pull request you may want to transition the issue into review. Click on a linked JIRA issue anywhere in Stash to see a dialog with the available workflow steps:

Your Admin needs to have set up linking with JIRA before you’ll see this. Read more about JIRA integration in Stash.

Autolink JIRA issues in markdown

When you mention JIRA a issue key in Stash, for example in a pull request description or comment, the key gets automatically linked:

Overview  Diff  Commits

Details

Pierre-Etienne Poiret created a pull request 6 days ago
A project from a earlier innovation week, updated to leverage Michael Heemskerk’s permissions improvements in 2.7 (STASHDEV-2057).
This will be merged after 2.7 is out, but the PR is opened to get early feedback.
You can click on the linked key to see details for the issue. Note that issue keys in a URL will link directly to the JIRA instance, as you'd expect. Read more about JIRA integration in Stash.

Support for multiple JIRA instances

Stash can now link to more than one JIRA server at a time, so different teams can work with their own projects in different JIRA instances, or a single team can link to issues across multiple JIRA servers.

Read more about JIRA integration in Stash.

Backup and restore beta

With the Stash 2.7 release we have made available a beta release of a backup and restore client for Stash. The Stash backup client locks access to Stash, checks that all Git and database operations have completed, and then performs a concurrent backup of the Stash database, repositories and data. You can download the Stash backup and restore client from the Atlassian Marketplace.

Although we are confident about the performance of this tool, we are interested in hearing how well it meets your requirements in actual use – this is why we are releasing the client as a beta. We look forward to your feedback!

Read more about backing up and restoring your Stash data.

Small improvements

Improved LDAP synchronisation performance

We have greatly improved the performance for LDAP synchronisation. For example, on a test LDAP server with 10,000 users and 10,000 groups, the time for a full synchronisation improved from 64 minutes to 4 minutes.

The Repository System Information plugin is now deprecated

The functionality of the repository system information plugin has now been moved into core Stash. The plugin will still work for Stash 2.x versions but is redundant as of Stash 2.7.

Syntax highlighters are now configurable

You can now update the extensions associated with different syntax highlighters using the stash-config.properties file in the Stash home directory. For more details see Configuring syntax highlighting for file extensions.

MySQL default isolation level

Stash 2.7.x uses READ_COMMITTED instead of the MySQL default isolation level (REPEATABLE_READ). This can result in exceptions when installing/upgrading to 2.7.x, if binary logging is enabled in your MySQL server. More details and a fix can be found in this KB article.

Fork synchronization with Stash 2.6

Today we're pleased to announce Stash 2.6, which introduces automated fork synchronization and audit logging. We've also added a repository search and polished some existing features.

If you are upgrading from an earlier version of Stash, please read the Stash upgrade guide.

The Stash 2.6 changelog is at the bottom of this page.

Fork synchronization

Fork syncing provides a way for your fork in Stash to be kept up-to-date with changes in the upstream repository, thus minimising the effort needed to do this manually. Stash can do this automatically, as long as you haven't modified the branches or tags in the fork.

If you have modified branches or tags in the fork, Stash will offer merge options:

Read more about using forks in Stash.

Audit logging

Stash now provides full audit logging. The most important audit events for each repository and project are displayed in Stash on the Settings tab (these are only visible to Stash admins and system admins):
Stash also creates full audit log files that can be found in the `<Stash home directory>/log/audit directory`. The level of logging can be configured via system properties. Note that we recommend an automated backup of log files.

Read more about audit logging in Stash. Plugin developers can specify that their plugin events should be added to the 'Audit log' view, and the full audit log file.

**Repository Quicksearch**

Quicksearch makes it easy to jump to a particular repository, without needing to know the name of the project it's in. Start typing to see a list of suggested repositories. If you type a `/`, text before that is matched against project names, and text after is matched against repository names. Note that wildcards and antglobs are not supported.

**Small improvements**

**Application navigator**

The new application navigator, on the left of the header, allows you to switch to your other applications, such as Atlassian JIRA and Bamboo – or any other web application – all from the Stash header:
Stash administrators can configure which apps appear in the navigator – just click **Configure** in the application navigator, or go to the Stash admin area and click **Application navigator**. See [Configuring the application navigator](#).

**List of public repositories**

Stash now displays a list of repositories for which anonymous access has been enabled – anonymous and logged-in users can choose **Repositories > View all public repositories**. See [Allowing public access to code](#).

**Deprecation of Java 6**

In version 3.0, Stash will no longer support Java 6.0, and will only support Java 7.0 and above. Stash 3.0 is expected to be released later in 2013. See [Supported platforms](#).

**Deprecation of Internet Explorer 8**

In version 3.0, Stash will no longer support Internet Explorer 8, and will only support Internet Explorer 9 and above. Stash 3.0 is expected to be released later in 2013. See [Supported platforms](#).

**Change log**

This section will contain information about the Stash 2.6 minor releases as they become available. These releases will be free to all customers with **active Stash software maintenance**.

Stash 2.5 release notes

12 June 2013

Go public with Stash 2.5

Today we're pleased to announce Stash 2.5, which fosters external participation and let's you enjoy even more streamlined code collaboration with public access to projects and repositories.

If you are upgrading from an earlier version of Stash, please read the Stash upgrade guide.

The Stash 2.5 changelog is at the bottom of this page.

Public access to projects and repositories

Public access provides anonymous (unauthenticated) users with browse access to specific repositories or entire projects in Stash. Anonymous users can see the source code in a repository, and clone the repository. Logged-in users get read access to a repository that has public access, so they can fork it and create pull requests.

Public access doesn't allow your source code to be changed in any way.

You can configure public access to repositories and projects separately. You can also disable anonymous access by setting a global system property. Please refer to the Stash API changelog for information about how plugin design is affected by public access.

Read more about public access in Stash.

Edit a pull request's destination branch

You can now change the destination branch for an active pull request – if you set the wrong destination when creating the PR, you no longer have to delete it and create a new one.
Get more context in diffs

We've added a way for you to see more lines of code in the diffs for pull requests and commits. Just click on the grey bars to see more context, up to the whole file if you want. There may also be grey bars at the top or bottom of the diff, if more context is available there.

![Image of a pull request edit screen]

Note that the expanded lines are displayed as greyed-out, to show that you can't comment on them.

Java OpenJDK is now supported

Java OpenJDK is widely used by Linux distributions. We've made your life easier by adding OpenJDK to the list of Java JDKs supported by Stash.

Just a reminder, Java 6 has been deprecated and will not be supported by Stash 3.0 (and later versions), which will be released later in 2013.

See Supported platforms for more information.

Small improvements

- JIRA issues that only appear in forks are now linked to the JIRA server.
- Stash now respects .mailmap files in Git repositories. See Git resources for details.
- The SCM Cache plugin is now bundled - see Scaling Stash for Continuous Integration performance.
- We've added a bit more control for CAPTCHA:
• There is now a system property switch to turn off (and hide) the Maximum login attempts control (look under 'Authentication' in the admin area).
• Administrators are now able to clear a user’s CAPTCHA status, from the user’s profile:

Stash 2.4 release notes

6 May 2013

Introducing Stash 2.4 – Forking in the Enterprise

Today we’re pleased to announce Stash 2.4, which introduces several key features to help you manage and collaborate on your Git repositories behind the firewall – forking, a workflow popularized in open source development, along with personal repositories and per-repository permissions.

Forks

Forks in Stash provide developers with a way to contribute code back to a repository for which they do not have write access. This extra control and flexibility of your development process lets you choose workflow scenarios that fit best. You can allow contractors to contribute to a project, or give developers the freedom to spike a project or prototype a feature, without risk to your core repositories.

Stash allows developers to fork a repository into any other project in Stash for which they have admin access. They can also create personal forks and then give others access by applying repository permissions.
Repository permissions

We've added repository permissions to Stash, which along with the already existing project and branch-level permissions, give you flexible yet fine-grained control over access to your repositories.

Individual Users

Groups

Read more about repository permissions in Stash.

Personal repositories

You can now create personal repositories, unrelated to other projects, that you can use for such purposes as storing private snippets of work, kick-starting your own project, or contributing a bug-fix for a project that you are not a member of. By default, personal repositories are not visible to other Stash users. However, you can use repository permissions to open up access to other individuals and groups.

Your personal repositories are listed on the Repositories tab of your profile page. Every Stash user can see your profile page, but they can only see those repositories that you have given them permission to view.
Read more about personal repositories in Stash.

Deprecation of Java 6

This is to give advance notice that Stash 3.0 will not support Java 6.0, and will only support Java 7.0 and above. Stash 3.0 is expected to be released later in 2013.

API changes

Please see the API changelog for any changes made for Stash 2.4.

Small improvements

Managing your Stash account

All the details of your Stash user account are now collected on your Stash account page. Use your account page to manage aspects of your Stash account, including changing your Stash password or avatar, and adding SSH keys.

To go to your account page simply choose Manage account from your user menu in the header:

Secret whitespace query parameter

Sometimes a diff is hard to read simply because multiple lines have only had the whitespace changed. To see just the important changes, use the w=1 (--ignore-all-space) query parameter, which is the same as the git diff option. For example, the URL could look like:

https://stash-your_organisation.com/projects/STASH/repos/your_repo/commits/c573ea24e70c9d2lee?w=1#your_repo_path/DiffRequest.java
Before:

```java
private Instructor ReposRepository, String filename, String targetId, List<Instructor> pets, Workspace whitespace; {
  + 28
  + 29
  + 30
  + 31
  + 32
  + 33
  + 34
  + 35
}
And later in the diff...

```java
private Instructor ReposRepository, String filename, String targetId, List<Instructor> pets, Workspace whitespace; {
  + 28
  + 29
  + 30
  + 31
  + 32
  + 33
  + 34
  + 35
}

After:

```java
private Instructor ReposRepository, String filename, String targetId, List<Instructor> pets, Workspace whitespace; {
  + 28
  + 29
  + 30
  + 31
  + 32
  + 33
  + 34
  + 35
}

### Stash 2.3 release notes

26 March 2013

With today's release of Stash 2.3 we introduce features for enterprise teams (single sign-on), Git operations (submodule recognition and branch deletion) and CI performance scaling (the SCM Cache plugin).

If you are upgrading from an earlier version of Stash, please read the Stash upgrade guide.

The Stash 2.3 changelog is at the bottom of this page.
Single sign-on with Crowd

Atlassian Crowd allows enterprise teams to integrate and deploy single sign-on (SSO) using popular directory servers such as Active Directory or OpenLDAP. Now your team members need only log in once to any of your Atlassian applications (JIRA, Confluence, Bamboo) to be able to access all of them, without repeatedly typing in their password.

- **IT administrators** can centralize user management through Crowd and provide SSO for all Atlassian apps with minimal configuration.
- **End-users** enjoy the convenience of logging in once to any Atlassian application, avoiding the interruption of repeated authentication across other applications. Log in once, and you’re automatically logged in to all applications connected to Crowd, including Stash.

Read more about using SSO with Stash.

Branch cleanup

We know that branches are often used for feature work, or for hot fixes that are destined to be applied to a stable or development branch. Once the code has been integrated into its destination branch it may often be desirable to delete the branch from Git as it is no longer required in the repository.

Stash now provides a simple way to delete the branch when you merge the pull request. As you might expect, Stash checks on a few things before allowing the deletion – the branch being merged will not be deleted if:

- The branch is the default repository branch.
- The user does not have permission to delete the branch.
- The branch is subject to an open pull request.

Read more about branch deletion when merging a pull request in Stash.
Git submodule recognition

Git submodules allow you to nest external Git repositories within the directory structure of your own repository. Submodules are commonly used to embed external codebases, such as shared libraries, that are updated independently of the main project.

Stash now makes it easy to identify Git submodules through the Stash user interface:

![Stash user interface showing submodules](image)

SCM Cache plugin for continuous integration performance

Stash instances with continuous integration (CI), or other automatic tooling set up to poll for changes, can end up with a high load on the Stash server due to frequent polling for changes, and bursts of repository clones when a change is detected.

The Stash SCM Cache plugin caches the pack files generated by Git during a clone operation on disk. This reduces the CPU load on your server and greatly improves response time when your server experiences repetitive requests from the continuous integration server.
Memory and CPU usage:

- Memory usage without SCM cache: 2GB
- Memory usage with SCM cache: 300MB
- CPU usage without SCM cache: 70%
- CPU usage with SCM cache: 20%

Read more about installing and configuring the Stash SCM Cache plugin.

Stash 2.2 release notes

05 March 2013

With today’s release of Stash 2.2 we introduce several capabilities for customising your Git development workflow – Git repository hooks, an API for hook integrations, and merge checks for pull requests.

If you are upgrading from an earlier version of Stash, please read the Stash upgrade guide.

The Stash 2.2 changelog is at the bottom.

Git repository hooks

Git hooks allow you to customise your development team’s workflow for any requirement they may have. Admins can enable and configure hooks for each repository, right within Stash, without having to install them on the file-system.

Stash comes bundled with repository hooks to let you start customising Stash straight off.

API for hook integrations

We’ve leveraged native Git hooks to create a new hooks API that allows developers to easily write their own hooks. Stash handles the persistence, packaging and per-repository configuration for your hooks, making it simple to extend Stash to suit your particular project’s needs. Read more about writing hooks for Stash in our revamped developer docs.

Furthermore, you can mix-and-match bundled Stash hooks with hooks from the Atlassian Marketplace. You can...
find and install these from within Stash – simply use the Add hook button on the hooks settings page to view available hooks from the marketplace.

**Merge checks for pull requests**

To help customise your workflow, you can now set checks to control when a pull request can be merged. Pull requests cannot be merged if the required checks have not been met. These checks are set separately on each repository in a Stash project:

- Require a minimum number of approvers – block merging of a pull request until it has been approved by the selected number of participants.
- Require a number of completed builds – stop pull requests from being merged if they have any unsuccessful builds, and until the set number of builds have completed.

Pull requests

- Requires [0-9] approvers
  
  At a minimum, pull requests must be approved by the number of users above before it can be merged.
- Requires a minimum of [0-9] successful builds
  
  If there are more than the specified number of builds, all of them will have to be successful in order to merge the pull request.

Read more about merge checks in Stash.

Stash 2.1 release notes

5th February 2013

With today’s release of Stash 2.1, we’ve added a slew of new features to simplify your Git development workflow by providing more contextual awareness of key JIRA issue and Bamboo build information. Additional new features provide quick clicks to your recently viewed pull requests and notifications of your tasks. More contextual information, more tracking capabilities, more automation – that’s Stash 2.1.

Pull request integration with JIRA

Developers create pull requests when their code is ready for peer review before merging a development branch into the main code line. To make pull requests most effective, reviewers need more context around the changes: What bug or feature is this pull request resolving? What are the details of those issues? Are any of the issues still open?

Pull requests now tightly integrate with JIRA, putting issue details front and center. View the status of an issue, along with it’s assignee and description to get the scoop without ever leaving Stash. This allows reviewers to

- Gain contextual awareness into the task which is being worked on by looking at descriptions, comments and attachments
- Quickly review the requirements for a new feature or bugfix
- Click straight through into JIRA, to keep issues up to date for upcoming releases

Read more about pull requests in Stash.

Build status API

Picture this: you’re about to click the 'merge' button, and then you pause to consider: did these changes pass all
To answer that, it's important to know what the latest build status of the branch is before the changes are integrated into master. But don't waste time navigating to your build system and sifting through test data to see whether the changes passed or failed. Stash 2.1 does it automatically. Our new build status API allows build servers, such as Bamboo and Jenkins, to publish build details to the pull request’s overview, giving you a quick idea of whether the pull request is good to merge or not.

But why stop with pull requests? The build status API will show you the build status of any commit, anywhere in Stash.

Read more about the build status API in our developer documentation.

**Project Avatars**

Give your projects some personality and make it easier to find them on the Dashboard with the new project avatars. Stash will randomly provide one of its colorful built-in avatars if you don't have one.

**Pull request inbox**

When you work across multiple repositories and projects, it can be hard to keep track of all the reviews you have to complete. We solved the problem by providing a globally accessible inbox, displaying all Pull Requests that are waiting for your approval. Use the inbox as a task list, and leave no pull request behind!

### Stash 2.0 release notes

**4th December 2012**

Meet the Enterprise-ready Stash 2.0 – Powered by Git. Controlled by You.

Imagine all the flexibility of Git with the control needed in the Enterprise. That's Stash 2.0. It comes packed with a heap of features including the highly anticipated branch permissions, @mentions, markdown support and a number of great improvements to pull requests. Additionally Stash 2.0 has been tested in very large environments to ensure you nail the landing of Git in your enterprise.

---

** Branch permissions**

---

Created in 2014 by Atlassian. Licensed under a Creative Commons Attribution 2.5 Australia License.
Per-branch "write" permissions for individuals and groups ensure that stable branches remain stable, and development branches foster collaboration. It's a whole new level of Enterprise security.

Some development workflows require that specific developers oversee merges into the master or release branches, while other developers work on bug-fix and feature branches. Branch Permissions let you turn this "gentlemen's agreement" into a seamless, enforceable process, reducing confusion and time wasted backing out changes that were merged prematurely.

Read more about branch permissions in Stash.

![Branch permissions](image)

Advanced branch permissions

Advanced Branch Permissions allow you to specify a pattern that is matched against branches and tags being pushed to Stash. This allows you to restrict pushes to multiple branches without the overhead of configuring them individually. Establishing naming conventions based on roles or functional areas (ie, "contractor_" or "userauth_") makes it even easier to set and standardize permissions throughout your organization.

GateKeeper

Branch Permissions can act as a "GateKeeper", allowing you to select a person who is responsible for ensuring that all the code going into production has been properly tested and reviewed. The integration with Pull Requests ensures that only the GateKeepers can merge the changes into the branch you are protecting.

@Mentions

Now you can use 'mentions' to notify another Stash user about the pull request descriptions and comments you are writing. When you mention a user, Stash sends them an email notification, to help streamline communication between your team members.

You can use mentions when writing pull request comments – simply start typing '@' and then the users name, and choose from the list that Stash offers. You can use quotes for unusual names, for example if it has spaces.
Markdown support

Stash now gives you a boost with support for markdown in comments and descriptions. Bring your words to life and get your point across quickly.

- **Emphasize** parts of your comment or create lists to bring your points across.
- Share links to requirements and issues related to the feature you are implementing.
- Provide code examples, formatted just like in your IDE.
- Include screenshots into the discussion for any UI focused features.

Read more about Markdown support in Stash.

Improved Pull Requests

Beyond @Mentions and Markdown support, Stash 2.0 features a huge number of improvements to Pull Requests.

Improved Diff view
The Diff view in Pull Requests has been engineered to maximise the available screen real-estate when reviewing a Pull Request. The file header and tree navigation now stalk to provide an almost full screen experience without having to switch into a special mode.

Faster page load times & keyboard shortcuts

The Pull Request tabs have been revamped to make them a whole lot faster to load and with the new keyboard shortcuts (1, 2, 3) it's also a whole lot faster to navigate between the tabs.

Comment indicators

With comment indicators on the filenames, it is now much easier to identify where the discussions are happening when in the Diff view.

New Comments are highlighted

New comments that have been added since your last visit are now highlighted in yellow, making it much easier to follow the conversation on the Pull Request overview.

Read more about Pull Requests in Stash.

Enterprise licenses

From growing startups to the Fortune 100, Atlassian Enterprise offers products and services that are built to match the needs of the largest enterprise customers. With the new Enterprise tiers for Stash, Atlassian has you covered no matter how big your organisation is. And of course, just like JIRA and Confluence, the Stash Enterprise licenses come with 24x7 Personalized Phone Support.

### Stash 1.3 release notes

**9th October 2012**

Meet the new, more social Stash – introducing Pull Requests

Pull requests provide your team with a quick and easy way to review code changes made on a branch, discuss those changes, and make further modifications before the branch is merged back to master or your main development branch.
Pull requests

With Stash and Pull Requests, code reviews become an integral part of your development process. Development happens on branches and when code is ready to be merged into the main branch a Pull Request is opened. Unless the code has been reviewed as part of a Pull Request, it does not get integrated back into the main branch. All the benefits of code review baked right into your workflow!

Creating a pull request is like starting a discussion. Your reviewers can see the changes you have made, comment on those changes and commit further changes and improvements to the branch if required. When everyone agrees, the branch can then be merged back to master or your main development branch.

Getting your code reviewed has never been easier – simply click the Pull Request button in the repository header, select the branch you’ve been working on, the branch you want to merge to, then add a short description and you’re done.

Read more about using pull requests in Stash.

Discussions

The essential thing about a pull request is the discussion that takes place around the code changes you are making. The overview captures the entire activity of the pull request. Comments on the diff, replies, or new commits to the branch.

Changed Files

Diffs for a Stash pull request highlight the changes that would result from the merge. The diff tree shows all modified files and, as you’d expect, you can click on any file to see exactly what has been added, deleted or
modified. Threaded comments right in the diff allow meaningful and contextual conversations about your code.

Commits

A pull request is dynamic! Not only can there be a lively discussion about code changes, but participants can commit new changes to the branch. Stash auto-updates the **Commits** tab of the pull request, so you can see exactly which commits will be merged. Stash is smart about comments, moving them along when lines are added or removed. If a line with a comment gets removed, you can still view the comment in the activity, but Stash marks the diff as *outdated* to let you know that this piece of code has been changed in recent commits.

Notifications

Whether someone added you as reviewer, commented on the pull request or merged your changes, Stash ensures you know what's going on by sending you email notifications about pull requests relevant to you.

Keyboard shortcuts

Stash has an evolving set of keyboard shortcuts, to help you work faster. Click the link when looking at any repository to refresh your memory about the available shortcuts.
README – simple project documentation

Stash now provides an appealing, yet simple, way to document the project right in the repository by rendering the content of .md and .txt files in the file view of the repository. If the file uses Markdown, that gets rendered straight to the screen.

Stash 1.2 release notes

7th August 2012

Atlassian is proud to present Stash 1.2, which provides greatly improved support for your enterprise database, rapid file searching and new Stash add-ons available from the Atlassian Marketplace.

See the change log for Stash 1.2.x minor releases.

**Highlights of this release:**

- MySQL, PostgreSQL, SQL Server and Oracle support
- Database migration
- File search
- Add-ons ecosystem
- Merge filter

**Providing feedback:**

Please log your votes and issues. They help us decide what needs doing, and are much appreciated!
MySQL, PostgreSQL, SQL Server and Oracle support

Stash now has support for all these major databases: MySQL, Oracle, PostgreSQL and Microsoft SQL Server. Choose the database that best fits your needs, or your system administrator is most familiar with, or that your company is already using. 

Database migration

Switch easily from the database embedded in Stash to your organisation’s existing technology stack, and migrate painlessly if your system administrators change the infrastructure. Stash scales and adapts as your requirements change.

File search
Stash’s new file search ensures that you can quickly find any file in your repository, without needing to check out the source. Just start typing any part of the file name into the search field and you’ll get a list of matches, fast. And you can filter by path, CamelCase (for example, AttrM to match AttributeMap) and file extension.

Add-ons ecosystem

Visualise information about your Git repository, comment on your code in-line, collect achievements when committing code or receive change notifications in HipChat. With almost a dozen add-ons available on the Atlassian Marketplace, you can extend Stash to suit your needs.

Merge filter

Merges can be faded out in the commit list, as in this screenshot, to make it easier to see the important details. Use the ‘t’ keyboard shortcut to toggle this effect.

Stash 1.1 release notes

19th June 2012

Atlassian is proud to present Stash 1.1, which provides a simple and secure solution for managing your Git repositories in the Enterprise.

See the change log for Stash 1.1.x minor releases.

Highlights of this release:

- SSH support
- Fast browsing
- Simple permissions
- Image diffs

Providing feedback:

Please log your votes and issues. They help us decide what needs doing, and are much appreciated!

1

SSH support

Developed from the ground up with enterprise level security as a #1 priority, Stash now supports SSH in addition to HTTPS. You can either use standard HTTPS authentication, or set up your public keys and connect to Stash using SSH. This resolves Stash's #1 feature request, focused on adding support for SSH security.

Developers can manage their own SSH keys, and add as many as they like. Stash administrators can grant or revoke the SSH keys of any user.

Stash 1.1 greatly improves productivity by making it easier to navigate and work with Git repositories.

**Recent repositories**

The new **Repositories** item in the Stash header is for those developers who work with several repositories and want a quick way to get back to one of those repositories.

**Mouse-less productivity**

Stash helps you to work even more efficiently without a mouse. Whether viewing changesets, browsing directories or jumping through your commit list, simply press ‘J’ or ‘K’ to move to the next or previous.

---

**Simple permissions**

Stash keeps you and your developers productive by providing a way to structure your repositories and manage permissions with a simple, yet powerful, user interface.

- **Global permissions** – delegate administration of projects to key users and groups, to give your developers the freedom to create and manage repositories
- **Projects permissions** – use simple permissions at the project level to control access to repositories for users and groups

The new permission screens provide a great overview of who has access to your projects, and managing permissions is even faster.

*More...*
Global Permissions

Stash makes diffs more accessible to everyone on your team, not just the back-end coders.

Have you ever tried to find the subtle difference between two images? That difference may be small like a text change or as large as a page redesign. Web designers, front-end developers, and maybe a few QA folks, rejoice and check out Stash’s interactive image diff viewer.

Maybe even more useful is ediffs. When viewing a diff it can sometimes be difficult to distinguish textual changes. Stash solves this with the addition of ediffs so you can clearly see the textual changes added or removed between two revisions.

Stash 1.0 release notes

1st May 2012

Atlassian is proud to present Stash 1.0, which provides a central place to create and manage Git repositories. It’s the place where all that distributed code comes back together, where you can find the latest official version of your project, and where you can keep track of what's going on.

See the change log for Stash 1.0.x minor releases.

Highlights of this release:

- Git repository management
- Projects and permissions
- Built for Git, focused on Enterprise
- Browse your source and history
- JIRA integration

Download
Providing feedback:

Please log your votes and issues. They help us decide what needs doing, and are much appreciated!

1

Git repository management

Stash provides a simple and powerful interface to create and manage Git repositories. Create repositories in a couple of clicks, and quickly choose those of your users and groups who will be contributors to the project, and those who will be just observers.

2

Projects and permissions

Since projects rarely consist of a single repository, Stash provides a convenient Project structure. This helps you to organise and manage repositories, and makes managing access to your repositories really simple.

With Stash you can empower end users to manage repositories themselves, while keeping control of the key administration functions. And because we want to make it easy for you to manage teams, Stash has a group management feature to help you grant permissions across your organisation.

3

Built for Git, focused on Enterprise

Stash has everything you need to create and manage Git repositories efficiently behind the safety of your own
firewall.

Stash doesn't force administrators to use a pre-packaged appliance and so give up control. Whether on Windows, Linux or MacOS X, Stash will feel right at home on all platforms.

With LDAP, Crowd and JIRA support, you can manage your team easily, whether they are a small number of users in Stash's internal directory, or 500 developers managed in your corporate directory.

User Directories 📇

The table below shows the user directories currently configured for Stash.

<table>
<thead>
<tr>
<th>Directory Name</th>
<th>Type</th>
<th>Order</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stash Internal Directory</td>
<td>Internal</td>
<td>3</td>
</tr>
<tr>
<td>Extralist Crowd</td>
<td>Internal</td>
<td>2</td>
</tr>
<tr>
<td>caviar-internal-directory</td>
<td>Internal</td>
<td>1</td>
</tr>
</tbody>
</table>

The order of the directories is the order in which they will be searched for users and groups. Changes to users and groups will be made in the first directory where Stash has permission to make changes. It is recommended that each user exist only in a single directory.

Keep track of commits to the repositories you're involved with and dive into the changesets to see exactly what has changed in the source. Use Stash's user interface to quickly navigate your repository and view annotated changes in an easily digestible way.

JIRA integration

JIRA integration saves users time when tracking and checking their development. Stash keeps track of all issues that are associated with commits. This allows users to navigate straight to the JIRA issues that are linked to the commits, and to see in JIRA an aggregate of all code changes related to an issue.

Stash 1.0.1 release notes

07 May 2012

The Atlassian Stash team is proud to announce the release of Stash 1.0.1.

We've fixed several bugs in this release. Please see the 'Updates and fixes in this release' section below for details.

Stash 1.0.1 is, of course, free to all customers with active Stash software maintenance.

Don't have Stash yet?

Take a look at all the features in the Stash 1.0 release notes and see what you are missing out on!

Upgrading from a previous version of Stash

If you are upgrading, please read the Stash 1.0 upgrade guide.

Stash 1.0 upgrade guide

The instructions on this page describe how to upgrade Stash from a previous version.

- For details of the latest Stash 1.0.x release, see the Stash 1.0 change log.
- For the latest and greatest Stash release, see Releases.

Please read the Supported platforms page for the full list of supported platforms for Stash.

Upgrade notes

These upgrade notes are specific to Stash 1.0.x. We strongly recommend that you upgrade Stash by following these steps:

1. Stop Stash!

   To stop Stash, run the following command in a terminal:

   - **Windows:**
     
     ```
     <Stash installation directory>\bin\stop-stash.bat
     ```
   
   - **Linux and Mac:**
     
     ```
     <Stash installation directory>/bin/stop-stash.sh
     ```

2. Back up your Stash instance!

   - Back up the Stash home directory. This is where your Stash data is stored. The home directory is specified either in `<Stash installation directory>\bin\setenv.bat` or in the STASH_HOME environment variable (on Windows).
   
   - If you are using an external database, back up this database. Follow the directions provided by the database vendor to do this.

3. Download and install Stash as usual

   In particular, you must redefine the Stash home directory, either in `<Stash installation directory>\bin\setenv.bat` or in the STASH_HOME environment variable (on Windows). See the following for more information:

   - Installing Stash on Windows
   - Installing Stash on Linux and Mac
If you made custom changes to the configuration of your existing Stash installation, for example for the port or context path, you will have to make these changes for the new installation as well.

4. Start Stash

See the following for more information:

- Installing Stash on Windows
- Installing Stash on Linux and Mac

Upgrading from Stash 1.0

There are no known issues associated with upgrading from Stash 1.0 to 1.0.1.

Developing for Stash

If you are a Stash plugin developer, please refer to our Stash developer documentation.

Checking for known issues and troubleshooting the Stash upgrade

If something is not working correctly after you have completed the steps above to upgrade your Stash installation, please check for known Stash issues and try troubleshooting your upgrade as described below:

- **Check for known issues.** Sometimes we find out about a problem with the latest version of Stash after we have released the software. In such cases we publish information about the known issues in the Stash Knowledge Base.

- If you encounter a problem during the upgrade and cannot solve it, please create a support ticket and one of our support engineers will help you.

### Stash security advisory 2012-09-04

This advisory discloses a security vulnerability that we have found in Stash and fixed in Stash 1.1.2.

**Customers who have downloaded and installed Stash** should upgrade their existing Stash installations to fix this vulnerability.

Atlassian is committed to improving product security. The vulnerability listed in this advisory has been discovered by Atlassian, unless noted otherwise. The reporter may also have requested that we do not credit them.

If you have questions or concerns regarding this advisory, please raise a support request at [http://support.atlassian.com/](http://support.atlassian.com/).
In this advisory:
  • XSS Vulnerability

XSS Vulnerability

Severity

Atlassian rates the severity level of this vulnerability as **High**, according to the scale published in **Severity Levels for Security Issues**. The scale allows us to rank the severity as critical, high, medium or low. This is an independent assessment and you should evaluate its applicability to your own IT environment. This vulnerability is **not** of Critical severity.

Description

We have identified and fixed a persistent cross-site scripting (XSS) vulnerability that affects Stash instances, including publicly available instances (that is, Internet-facing servers). XSS vulnerabilities allow an attacker to embed their own JavaScript into a Stash page.

You can read more about XSS attacks at cgisecurity.com, The Web Application Security Consortium and other places on the web.

This vulnerability affects all supported versions of Stash, and has been fixed in Stash 1.1.2. This issue can be tracked here: [STASH-2676 - Persistent Cross Site Scripting Vulnerability](#) **CLOSED**

Risk Mitigation

We strongly recommend upgrading your Stash installation to fix this vulnerability. Please see the 'Fix' section below.

Fix

**Upgrade**

The vulnerability and fix version are described in the 'Description' section above.

We recommend that you upgrade to the latest version of Stash, if possible. For a full description of the latest version of Stash, see the release notes. You can download the latest version of Stash from the download centre.

Patches are not available for this vulnerability.

**Stash security advisory 2014-02-26**

This advisory details a critical security vulnerability that we have found in Stash and fixed in a recent versions of Stash.

  • **Customers who have downloaded and installed Stash** should upgrade their existing Stash installations to fix this vulnerability.
  • **Atlassian OnDemand customers** are not affected because OnDemand does not include Stash.

The vulnerability affects all versions of Stash up to and including 2.5.3, 2.6.4, 2.7.5 and 2.8.3.

It does **not** affect versions 2.5.4, 2.6.5, 2.7.6, 2.8.4, 2.9.X, 2.10.X.

Atlassian is committed to improving product security. We fully support the reporting of vulnerabilities and we appreciate it when people work with us to identify and solve the problem.

If you have questions or concerns regarding this advisory, please raise a support request at [http://support.atlassian.com](http://support.atlassian.com).

User privilege escalation

Severity

Atlassian rates the severity level of this vulnerability as **critical**, according to the scale published in **Severity Levels of Security Issues**. The scale allows us to rank the severity as critical, high, moderate or low.

This is an independent assessment and you should evaluate its applicability to your own IT environment.
Description

We have identified and fixed a vulnerability in Stash which allowed unauthenticated users to commit actions on behalf of any other authorised user. In order to exploit this vulnerability, an attacker requires access to your Stash web interface.

The Stash server is only vulnerable if it has been configured to be a part of an Application link with Trusted Applications authentication.

The vulnerability affects all supported versions of Stash up to and including 2.5.3, 2.6.4, 2.7.5 and 2.8.3. It has been fixed in the Stash security patch releases 2.5.4, 2.6.5, 2.7.6, 2.8.4. The vulnerability does not affect the Stash 2.9 and 2.10 releases. The issue is tracked in [STASH-4122 - Privilege escalation](http://jira.atlassian.com/browse/STASH-4122) - CLOSED.

Risk Mitigation

If you are unable to upgrade or patch your Stash server you can do the following as a temporary workaround:

- Block access to your Stash server web interface from untrusted networks, such as the Internet.
- Remove any Application links that use Trusted Applications authentication and re-create them using OAuth.

Fix

This vulnerability can be fixed by upgrading Stash to one of the security patch releases or any release of Stash higher than 2.9.0. If required, there is also a patch available for this vulnerability for all supported versions of Stash. If you have any questions, please raise a support request at [http://support.atlassian.com](http://support.atlassian.com). We recommend upgrading.

The Security Patch Policy describes when and how we release security patches and security upgrades for our products.

Upgrading Stash

Upgrade to one of the Stash patch releases, 2.5.4, 2.6.5, 2.7.6, 2.8.4, which fixes this vulnerability, or one of the unaffected releases, 2.9 or a later version. For a full description of these releases, see the [Stash Release Notes](http://jira.atlassian.com/wiki/display/STASH/Release+Notes).

Patches

Binary patches are not available for this advisory. You need to either install one of the patch releases or apply recommended temporary workarounds.

Getting started

One "gotcha" when starting with Git is the way in which it pushes branches by default. On older versions of Git, pushing without arguments would push all branches that have the same name both locally and remotely. This can result in unexpected behaviour if you have old branches that complain when the remote branch is updated. It can even be quite dangerous if you do a force push and it reverts changes on the server. You can see the current value by running:

```
git config push.default
```

If this value is blank or 'matching', it is our recommendation that you reconfigure it to use 'upstream'.

```
git config --global push.default upstream
```

There has been some discussion around changing the default behaviour of Git.

Git .mailmap

The Git .mailmap feature is useful locally, and in Stash repositories, to map multiple commit identities to the one Stash user – this can be used to tidy up your Git histories.

The Git documentation for .mailmap has configuration details (see the "MAPPING AUTHORS" section).

Stash FAQ
Repositories

Q: I'm getting a "broken pipe" error when pushing my commits.
A: This error occurs when the amount of data you're trying to push in one go exceeds Git's http post buffer. Just run the following command to increase it to 500MB.

```
git config http.postBuffer 524288000
```

See Git push fails with 'fatal: The remote end hung up unexpectedly'.

Q: Does Stash support Mercurial (Hg)? What about other version control systems?
A: Currently Stash does not support Mercurial. We will be gauging demand for Mercurial support as we move forward -

[STASH-2469] - Include Mercurial (Hg) support in Stash

Q: Why did you create a new product for Git repository management? Couldn't you build this into FishEye?

Q: Does FishEye require Stash? Does Stash require FishEye? Can they be used together?

Integration

Q: Does Stash work with JIRA? If so, what version of JIRA do I need to run Stash?
Q: Will Stash integrate with any other Atlassian Tools? Crowd? Bitbucket? SourceTree?
Q: Will Stash be available for Atlassian OnDemand?

Licensing

Q: Does my Stash license have to match the number of users in my external directory (LDAP, Active Directory, Crowd or JIRA)?
Q: The number of users in my instance has exceeded my license count. Will Stash still work properly?

Data recovery and backups

Q: Can I restore the .tar file created by the backup client into a database that is different from my original one (i.e. Oracle -> MySQL, etc.)?
Q: I forgot the user/password for my old database schema. How will I perform the restore? How does it work?
Q: What is the difference between the parameter pairs "stash.user & stash.password" and "jdbc.user & jdbc.password"?
Q: What about Git repository management in FishEye and Crucible?

A: The current Git repository management feature in FishEye will be deprecated in the near future. We encourage those interested in Git repository management to check out Stash.

Q: Why did you create a new product for Git repository management? Couldn't you build this into FishEye?

A: In FishEye 2.7 we added basic capabilities to host and manage Git repositories within FishEye. However, as we were planning future releases, we realized that the architecture of FishEye, built to index, browse and search across various SCMs, was not adequate for a DVCS repository management tool.

Therefore we have made the decision to build a new product, with a clear focus: hosting and managing Git repositories. Instead of a “Jack of all trades”, we will have two products that are focused on 2 very different tasks:

1. Stash – Host, manage and collaborate on Git repositories
2. FishEye – Track, search and browse Subversion, Perforce, Git, Mercurial and CVS repositories in one place.

Q: Does FishEye require Stash? Does Stash require FishEye? Can they be used together?

A: FishEye and Stash are two separate standalone products that do not require each other.

If you are using multiple source code management systems (SCM) at your organization it makes sense to use both FishEye and Stash. While you are managing your Git repositories with Stash, you can use FishEye to browse, search and reference code from other SCMs including Subversion.

Also, if you are using Git, Stash will provide your Git repository management, and FishEye will be a central place to keep track of changes and search for code across your repositories.

Integration

Q: Does Stash work with JIRA? If so, what version of JIRA do I need to run Stash?

A: Stash works with JIRA 4.3+. However, you will require the latest version of the JIRA/FishEye plugin to view commits in JIRA. See our documentation on JIRA integration.

Q: Will Stash integrate with any other Atlassian Tools? Crowd? Bitbucket? SourceTree?

A: Stash currently integrates with the JIRA issues tracker, SourceTree DVCS Mac client and Crowd user management solution. You can also connect to Stash via Bamboo to run your builds and deployments and we are planning even tighter integrations in the future.

Q: Will Stash be available for Atlassian OnDemand?

A: Atlassian Stash will not be available in OnDemand. If you are looking for a distributed version control solution to use with Atlassian OnDemand, we recommend using Bitbucket, our cloud based Git and Mercurial source code hosting solution. Bitbucket connects to Atlassian OnDemand via the JIRA DVCS connector.

Licensing

Q: Does my Stash license have to match the number of users in my external directory (LDAP, Active Directory, Crowd or JIRA)?

A: No. You can control which users in your external directory have access to Stash, so that the license limit is not exceeded. A user is by definition any account that has permission to log into the Stash application. If you
synchronise Stash with an external user directory, you can grant access to Stash to a subset of users, so as to stay below your license limit. The Global permissions page explains in detail how to manage login rights for users and groups in Stash.

Q: The number of users in my instance has exceeded my license count. Will Stash still work properly?

A: As stated in the Global permissions document, any user assigned "Stash User" permission or higher, granted to the individual or via a group, will count towards the license limit. Stash will not allow you to grant the "Stash User" permission if this will exceed the license limit while manually adding users using Stash UI. However, if you happen to exceed the license limit by connecting your Stash instance to a User Directory that contains more users than you license allows you to have, Stash will display a banner with the content below:

⚠️ You have more users than your license allows.

Users will not be able to push commits to repositories until you restrict the number of active users to match your license or you upgrade your current license.

To fix that bear in mind that users don’t have to be removed from the database in order to reduce their license count. You merely have to make sure that they no longer have access to Stash via the "Stash User" permission through individual or group assignments.

Data recovery and backups

Q: Can I restore the .tar file created by the backup client into a database that is different from my original one (i.e. Oracle -> MySQL, etc.)?

A: Yes you can, as long as you specify all the jdbc parameters (jdbc.override, jdbc.driver, etc.) when running the restore. Please read Restoring Stash into a newly created DB for more details.

Q: I forgot the user/password for my old database schema. How will I perform the restore? How does it work?

A: As described in Restoring Stash into a newly created DB, the restore client will only restore into an empty home directory and an empty database. The new database should be configured following the instructions in Connecting Stash to an external database and its sub-page that corresponds to your database type. If you want to use a different type of database or a different user/password, you just need to specify all the jdbc parameters (jdbc.override, jdbc.driver, etc) when running the restore.

Q: What is the difference between the parameter pairs "stash.user & stash.password" and "jdbc.user & jdbc.password"?

A: stash.user and stash.password hold the credentials for a Stash sys admin user. They are only used during the backup procedure so that the backup client can lock Stash and instruct Stash to perform the database-agnostic backup. The backup client does not need database credentials because the Stash system performs the database backup.

jdbc.user and jdbc.password are only used during the restore procedure when jdbc.override is set to true. They are used to connect to the newly-installed database.

How do I change the external database password

You can change the password the Stash uses to connect to an external database, however you don’t do this from the Stash Administration area – you must follow the procedure described below.

To change the password that Stash uses when connecting to an external database:

1. Stop Stash, on Windows, or on Linux and Mac.
2. Get your database administrator to change the password on your database.
3. Go to your Stash home directory.
   Edit the `stash-config.properties` file to change the line that looks like:
   ```
   jdbc.password=MY_PASSWORD
   ```
   replacing `MY_PASSWORD` with your new database password.
4. Restart Stash, on Windows, or on Linux and Mac.

### Stash home directory

#### What is the Stash home directory?

The Stash home directory is where your Stash data is stored. The home directory location is defined either by the `STASH_HOME` environment variable, or in the `STASH_HOME` line of:

- `<Stash installation directory>\bin\setenv.bat`, on Windows
- `<Stash installation directory>/bin/setenv.sh`, on Linux and Mac.

⚠️ You should not locate your Stash home directory inside the `<Stash installation directory>` — they should be entirely separate locations. If you do put the home directory in the `<Stash installation directory>` it will be overwritten, and lost, when Stash gets upgraded. And by the way, you’ll need separate Stash home directories if you want to run multiple instances of Stash.

⚠️ Where possible, you should choose a location for your Stash home directory that will never need to be moved. Some home contents are location-sensitive, so moving the home directory may corrupt them. Stash attempts to update contents when it detects that the home directory has moved, but the safest approach is to avoid the issue altogether by leaving the home directory in the same location.

#### What is in the Stash home directory?

Your Stash home directory contains the following directories and files:

<table>
<thead>
<tr>
<th>Path</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>caches</td>
<td>Contains cache and index files. It should be safe for these files to be deleted between application restarts; however, these files must not be modified or deleted while Stash is running.</td>
</tr>
<tr>
<td>config</td>
<td>Contains application configuration.</td>
</tr>
<tr>
<td>data</td>
<td>Contains the Git repositories, project avatars, and the embedded HSQL database if an external database is not configured.</td>
</tr>
<tr>
<td>export</td>
<td>Contains dump files produced during database migrations.</td>
</tr>
<tr>
<td>lib</td>
<td>As of Stash 2.1, can contain third-party jars such as the MySQL JDBC driver.</td>
</tr>
<tr>
<td>lib/native</td>
<td>As of Stash 2.1, can contain native libraries, such as Tomcat's APR-based native library.</td>
</tr>
<tr>
<td>log</td>
<td>Contains log files for Stash.</td>
</tr>
<tr>
<td>plugins</td>
<td>Contains plugin related data (such as externally uploaded plugins) for Stash.</td>
</tr>
<tr>
<td>tmp</td>
<td>Contains temporary files created by the system. Its contents can safely be deleted when Stash is not running.</td>
</tr>
</tbody>
</table>
stash-config.properties | Allows configuring various aspects of how Stash behaves, such as its database connection pool size and the location of the Git binary to use. This file will be created automatically during a database migration. It can be created manually otherwise. See Stash config properties for further information.

Securing the Stash home directory

The internal database files, the migration dump files and stash-config.properties all contain information that may be considered secret (server settings, salted and hashed user passwords, database passwords, etc).

For production use, we strongly recommend that you secure this directory against unauthorised access.

We recommend the following precautions:

- Assign a separate restricted user account on the machine for running Stash (not a root/administrator user)
- If you wish to run Stash on port 80, use a separate http front end as described in Integrating Stash with Apache HTTP Server (do not run as root/Administrator if security of the home directory is important to you)
- Ensure that only the user running Stash can access the Stash home directory, and that this user has read, write and execute permissions, by setting file system permissions appropriately for your operating system.

About the repositories

As noted above, data contains the Git repositories being managed by Stash, where “managed by Stash” are the operative words. The repositories are for Stash to interact with, and they are configured and managed accordingly. They are not a mechanism for configuring Stash behaviour. We strongly recommend that customers never modify them, nor interact with them directly. They are intentionally structured in a way which does not lend itself well to direct interaction.

Being Git repositories, there are certainly standard aspects to how the repositories on disk are stored and how they function. However, the exact way they are configured can and does change between Stash releases. Stash makes no effort to preserve unexpected configuration changes which have been applied by customers, and such changes may cause failures at runtime or during upgrades. If there is an aspect of Stash’s behaviour you wish to configure, please open a feature request on jira.atlassian.com rather than trying to modify the repositories directly.

Repositories are location sensitive. Moving your Stash home directory will result in the system being locked (briefly) on startup while Stash updates the repositories on disk. Assuming the updates are applied successfully, the system will then unlock itself for normal usage.

Where possible, please choose a Stash home location which will not need to be changed later.

Raising a request with Atlassian Support

If you encounter any problems when setting up or using Stash, please let us know — we’re here to help!

You may want to search the following first:

- the Atlassian Answers site (the Stash forum), where Atlassian staff and Stash users can answer your questions.
- the Stash Knowledge Base.

If you’ve found a bug in Stash, or want to request a feature or improvement, raise a ticket in the Stash project of our public issue tracker. Try searching for similar issues - voting for an existing issue is quicker, and avoids duplicates.

If you still need assistance, please raise a support request, either from within Stash or on the Atlassian Support site, as described in the following sections.
Providing as much information as possible about your Stash installation with your initial request will help our Support Engineers to give you a faster and more complete response.

On this page:
- Raising a Support Request from within Stash
- Raising a Support request yourself at Atlassian Support
- Information you should provide

Raising a Support Request from within Stash

This method depends on having a mail server configured for Stash that supports large zip file attachments.

1. Log in to Stash (as a System Administrator) and go to the admin area.
2. Click Atlassian Support Tools (under 'Support') then Support Request.
3. Provide as much information as possible in the Description, including steps to replicate the problem, and any error messages that are appearing on the console or in the logs. For performance issues, please include profiling logs. See the section below about information you should provide.
4. Click Send.

This will produce a zip file containing the information categories selected from the list and will email this to Atlassian Support. You will receive an email advising you of details of the Support Request that was automatically created, and you will receive emailed updates about progress on your issue. You can also see the status of your request directly by visiting the Atlassian Support System.

Raising a Support request yourself at Atlassian Support

1. Log in to Stash (as a System Administrator) and go to the admin area.
2. Click Atlassian Support Tools (under 'Support') then Support Zip.
3. Select information categories to include in the zip file.
4. Click Create.

The zip file is created in the home directory of the Stash server, for example <STASH_HOME>\export\Stash_support_2013-11-17-20-49-18.zip.

When you now go to Atlassian Support and create a Support Request, you can attach the Support Zip file to the request.

Please provide as much information as possible in the request, including steps to replicate the problem, and any error messages that are appearing on the console or in the logs. For performance issues, please include profiling logs. See the section below about information you should provide.

Information you should provide

In addition to the logs and configuration information that you can include in the Support Request zip file, the following information can help to give you a faster response:

Environment details
- Stash version
- Java version (for example OpenJDK 1.7.0 JRE)
- Git and Perl versions
- Operating system (for example, Windows 7, Mac OS X 10.6.8)
- Database type (for example, MySQL) and version
- Browsers and versions
- Network topology - is Stash running behind a reverse proxy? Is that secured using HTTPS (SSL)?

Configuration
- Java settings, including JVM_MINIMUM_MEMORY, JVM_MAXIMUM_MEMORY

Logs
You may need to adjust the logging level, or enable profiling in Stash, in order to get more detailed logs. See Sta
sh debug logging.

- Debug logs – Stash debug logs can be found in `<STASH_HOME>/log`.
- Profiling logs – Stash profiling logs can help with analyzing performance issues and can be found in `<STASH_HOME>/log`.

Performance factors

- Number of concurrent Git clones
- Number of users
- The size of the .git directory
- CPU spec, number of cores, whether hyperthreading is enabled
- RAM and cache sizes

Integrations

- Other Atlassian applications (and their versions)
- Which build servers are integrated with Stash, if any?
- Are Application Links configured?

Bug fixing policy

Summary

- Atlassian Support will help with workarounds and bug reporting.
- Critical bugs will generally be fixed in the next maintenance release.
- Non critical bugs will be scheduled according to a variety of considerations.

Raising a Bug Report

Atlassian Support is eager and happy to help verify bugs — we take pride in it! Please open a support request in our support system providing as much information as possible about how to replicate the problem you are experiencing. We will replicate the bug to verify, then lodge the report for you. We’ll also try to construct workarounds if they’re possible.

Customers and plugin developers are also welcome to open bug reports on our issue tracking systems directly. Use http://jira.atlassian.com for the stand-alone products and http://studio.atlassian.com for JIRA Studio and Atlassian OnDemand.

When raising a new bug, you should rate the priority of a bug according to our JIRA usage guidelines. Customers should watch a filed bug in order to receive e-mail notification when a "Fix Version" is scheduled for release.
How Atlassian Approaches Bug Fixing

Maintenance (bug fix) releases come out more frequently than major releases and attempt to target the most critical bugs affecting our customers. The notation for a maintenance release is the final number in the version (ie the 1 in 3.0.1).

If a bug is critical (production application down or major malfunction causing business revenue loss or high numbers of staff unable to perform their normal functions) then it will be fixed in the next maintenance release provided that:

- The fix is technically feasible (i.e. it doesn't require a major architectural change).
- It does not impact the quality or integrity of a product.

For non-critical bugs, the developer assigned to fixing bugs prioritises the non-critical bug according to these factors:

- How many of our supported configurations are affected by the problem.
- Whether there is an effective workaround or patch.
- How difficult the issue is to fix.
- Whether many bugs in one area can be fixed at one time.

The developers responsible for bug fixing also monitor comments on existing bugs and new bugs submitted in JIRA, so you can provide feedback in this way. We give high priority consideration to security issues.

When considering the priority of a non-critical bug we try to determine a 'value' score for a bug which takes into account the severity of the bug from the customer’s perspective, how prevalent the bug is and whether roadmap features may render the bug obsolete. We combine this with a complexity score (i.e. how difficult the bug is). These two dimensions are used when developers self serve from the bug pile.

How to report a security issue

Finding and Reporting a Security Issue

If you find a security issue in the product, open an issue on https://jira.atlassian.com in the relevant project.

- Set the security level of the bug to 'Reporters and Developers'.
- Set the priority of the bug to 'Blocker'.
- Provide as much information on reproducing the bug as possible.

All communication about the security issue should be performed through JIRA, so that Atlassian can keep track of the issue and get a patch out as soon as possible.

If you cannot find the right project to file your issue in, email the details to security@atlassian.com.

When reporting a security vulnerability, please keep in mind the following:

We need a technical description that allows us to assess exploitability and impact of the issue.

- Provide steps to reproduce the issue, including any URLs or code involved.
- If you are reporting a cross-site scripting (XSS), your exploit should at least pop up an alert in the browser. It is much better if the XSS exploit shows user's authentication cookie.
- For a cross-site request forgery (CSRF), use a proper CSRF case when a third party causes the logged in victim to perform an action.
- For a SQL injection, we want to see the exploit extracting database data, not just producing an error message.
- HTTP request / response captures or simply packet captures are also very useful to us.

Please refrain from sending us links to non-Atlassian web sites, or reports in PDF / DOC / EXE files. Image files are ok. Make sure the bug is exploitable by someone other than the user himself (e.g. "self-XSS").

Without this information it is not possible to assess your report and it is unlikely to be addressed.
We are not looking for the reports listing generic "best practice" issues such as:

- Specific cookies being not marked as Secure or HTTPOnly
- Presence or absence of HTTP headers (X-Frame-Options, HSTS, CSP, nosniff and so on)
- Clickjacking
- Mixed HTTP and HTTPS content
- Auto-complete enabled or disabled
- SSL-related issues

We are also not looking for reports on the following bug classes:

- Username enumeration using login or password reset features. While username enumeration can be a vulnerability in web applications, most of Atlassian products and websites include a number of social features. As a result, usernames can be discovered by design in a number of ways.

**New features policy**

**Summary**

- We encourage and display customer comments and votes openly in our issue tracking system, [http://jira.atlassian.com](http://jira.atlassian.com).
- We do not publish roadmaps.
- Product Managers review our most popular voted issues on a regular basis.
- We schedule features based on a variety of factors.
- Our Atlassian Bug Fixing Policy is distinct from our Feature Request process.
- Atlassian provides consistent updates on the top 20 feature/improvement requests (in our issue tracker systems).

**How to Track what Features are Being Implemented**

When a new feature or improvement is scheduled, the 'fix-for' version will be indicated in the JIRA issue. This happens for the upcoming release only. We maintain roadmaps for more distant releases internally, but because these roadmaps are often pre-empted by changing customer demands, we do not publish them.

**How Atlassian Chooses What to Implement**

In every **major release** we aim to implement highly requested features, but it is not the only determining factor. Other factors include:

- **Customer contact**: We get the chance to meet customers and hear their successes and challenges at Atlassian Summit, Atlassian Unite, developer conferences, and road shows.
- **Customer interviews**: All product managers at Atlassian do customer interviews. Our interviews are not simply to capture a list of features, but to understand our customers' goals and plans.
- **Community forums**: There are large volumes of posts on answers, of votes and comments on jira.atlassian.com, and of conversations on community forums like groups on LinkedIn.
- **Customer Support**: Our support team provides clear insights into the issues that are challenging for customers, and which are generating the most calls to support.
- **Atlassian Experts**: Our Experts provide insights into real-world customer deployments, especially for customers at scale.
- **Evaluator Feedback**: When someone new tries our products, we want to know what they liked and disliked and often reach out to them for more detail.
- **In product feedback**: The JIRA Issue Collectors that we embed our products for evaluators and our Early Access Program give us a constant pulse on how users are experiencing our product.
- **Usage data**: Are customers using the features we have developed?
- **Product strategy**: Our long-term strategic vision for the product.

**How to Contribute to Feature Development**

**Influencing Atlassian’s release cycle**
We encourage our customers to vote on feature requests in JIRA. The current tally of votes is available online in our issue tracking system, http://jira.atlassian.com. Find out if your improvement request already exists. If it does, please vote for it. If you do not find it, create a new feature or improvement request online.

**Extending Atlassian Products**

Atlassian products have powerful and flexible extension APIs. If you would like to see a particular feature implemented, it may be possible to develop the feature as a plugin. Documentation regarding the plugin APIs is available. Advice on extending either product may be available on the user mailing-lists, or at Atlassian Answers.

If you require significant customisations, you may wish to get in touch with our partners. They specialise in extending Atlassian products and can do this work for you. If you are interested, please contact us.

**Patch policy**

**Patch Policy**

Atlassian will only provide software patches in extremely unusual circumstances. If a problem has been fixed in a newer release of the product, Atlassian will request that you upgrade your instance to fix the issue. If it is deemed necessary to provide a patch, a patch will be provided for the current release and the last maintenance release of the last major version only.

Patches are issued under the following conditions:

- The bug is critical (production application down or major malfunction causing business revenue loss or high numbers of staff unable to perform their normal functions) AND a patch is technically feasible (i.e., it doesn't require a major architectural change)
- OR
- The issue is a security issue, and falls under our Security Patch Policy.

Atlassian does not provide patches for non-critical bugs.

Provided that a patch does not impact the quality or integrity of a product, Atlassian will ensure that patches supplied to customers are added to the next maintenance release. Customers should watch a filed bug in order to receive e-mail notification when a "Fix Version" is scheduled for release.

Patches are generally attached to the relevant http://jira.atlassian.com issue.

**Security advisory publishing policy**

**Publication of Security Advisories**

When a critical severity security vulnerability in an Atlassian product is discovered and resolved, Atlassian will inform customers through the following mechanisms:

- We will post a security advisory in the latest documentation of the affected product at the same time as releasing a fix for the vulnerability.
- We will send a copy of all posted security advisories to the 'Technical Alerts' mailing list for the product concerned.
  
  Note: To manage your email subscriptions and ensure you are on this list, please go to my.atlassian.com and click 'Communications Centre' near the top right of the page.
- If the person who reported the vulnerability wants to publish an advisory through some other agency, such as CERT, we will assist in the production of that advisory and link to it from our own.

If you want to track non-critical severity security vulnerabilities, you need to monitor the issue trackers for the relevant products on http://jira.atlassian.com. For example, https://jira.atlassian.com/browse/JRA for JIRA and https://jira.atlassian.com/browse/CONF for Confluence. Security issues in trackers will be marked with a "security" label. All security issues will be listed in the release notes of the release where they have been fixed, similar to other bugs.
One of the ways to monitor updates to security issues is subscribing to the results of a sample search via email or RSS.

Security patch policy

Product Security Patch Policy

Atlassian makes it a priority to ensure that customers' systems cannot be compromised by exploiting vulnerabilities in Atlassian products.

Scope

This page describes when and how we release security patches and security upgrades for our products. It does not describe the whole of disclosure process that we follow. This policy excludes OnDemand and Bitbucket, since these services are always patched by Atlassian without additional notifications.

Critical vulnerabilities

When a Critical security vulnerability is discovered by Atlassian or reported by a third party, Atlassian will do all of the following:

- Issue a new, fixed release for the current version of the affected product as soon as possible, usually in a few days.
- Issue a binary patch for the current release.
- Issue a binary patch for the latest maintenance release of the previous version of the product.
- Patches for older versions or releases normally will not be issued.

Patches will be attached to the relevant JIRA issue. You can use these patches as a "stop-gap" measure until you upgrade your installation in order to fully fix the vulnerability.

Non-critical vulnerabilities

When a security issue of a High, Medium or Low severity is discovered, Atlassian will do all of the following:

- Include the fix into the next scheduled release, both for the current and previous maintenance versions.
- Where practical, provide new versions of plugins or other components of the product that can be upgraded independently.

You should upgrade your installation in order to fix the vulnerability.

Other information

Severity level of vulnerabilities is calculated based on Severity Levels for Security Issues.

Visit our general Atlassian Patch Policy as well.

Examples

Example 1: A critical severity vulnerability is found in a (hypothetical current release) JIRA 5.3.2. The last bugfix release in 5.2.x branch was 5.2.3. In this case, a patch will be created for 5.3.2 and 5.2.3. In addition, new bugfix releases, 5.3.3 and 5.2.4, which are free from this vulnerability, will be created in a few days.

Example 2: A high or medium severity vulnerability is found in the same release as in the previous example. The fix will be included into the currently scheduled releases 5.3.3 and 5.2.4. Release schedule will not be brought forward and no patches will be issued. If the vulnerability is in a plugin module, then a plugin upgrade package may still be supplied.

Severity levels for security issues
Severity Levels

Atlassian security advisories include a severity level. This severity level is based on our self-calculated CVSS score for each specific vulnerability. CVSS is an industry standard vulnerability metric. You can learn more about CVSS at FIRST.org web site.

CVSS scores are mapped into the following severity ratings:

- Critical
- High
- Medium
- Low

An approximate mapping guideline is as follows:

<table>
<thead>
<tr>
<th>CVSS score range</th>
<th>Severity in advisory</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 – 2.9</td>
<td>Low</td>
</tr>
<tr>
<td>3 – 5.9</td>
<td>Medium</td>
</tr>
<tr>
<td>6.0 – 7.9</td>
<td>High</td>
</tr>
<tr>
<td>8.0 – 10.0</td>
<td>Critical</td>
</tr>
</tbody>
</table>

Below is a summary of the factors which illustrate types of vulnerabilities usually resulting in a specific severity level. Please keep in mind that this rating does not take into account details of your installation.

**Severity Level: Critical**

Vulnerabilities that score in the critical range usually have most of the following characteristics:

- Exploitation of the vulnerability results in root-level compromise of servers or infrastructure devices.
- The information required in order to exploit the vulnerability, such as example code, is widely available to attackers.
- Exploitation is usually straightforward, in the sense that the attacker does not need any special authentication credentials or knowledge about individual victims, and does not need to persuade a target user, for example via social engineering, into performing any special functions.

For critical vulnerabilities, is advised that you patch or upgrade as soon as possible, unless you have other mitigating measures in place. For example, if your installation is not accessible from the Internet, this may be a mitigating factor.

**Severity Level: High**

Vulnerabilities that score in the high range usually have some of the following characteristics:

- The vulnerability is difficult to exploit.
- Exploitation does not result in elevated privileges.
- Exploitation does not result in a significant data loss.

**Severity Level: Medium**

Vulnerabilities that score in the medium range usually have some of the following characteristics:

- Denial of service vulnerabilities that are difficult to set up.
- Exploits that require an attacker to reside on the same local network as the victim.
- Vulnerabilities that affect only nonstandard configurations or obscure applications.
- Vulnerabilities that require the attacker to manipulate individual victims via social engineering tactics.
- Vulnerabilities where exploitation provides only very limited access.

**Severity Level: Low**

Vulnerabilities in the low range typically have very little impact on an organisation’s business. Exploitation of such vulnerabilities usually requires local or physical system access.

**Building Stash from source**

This page has moved!

But you really wanted to build a plugin anyway, right?

**Contributing to the Stash documentation**

Would you like to share your Stash hints, tips and techniques with us and with other Stash users? We welcome your contributions.

**Blogging your technical tips and guides**

Have you written a blog post describing a specific configuration of Stash or a neat trick that you have discovered? Let us know, and we will link to your blog from our documentation.

**Contributing documentation in other languages**

Have you written a guide to Stash in a language other than English, or translated one of our guides? Let us know, and we will link to your guide from our documentation.

**On this page:**

- Blogging your technical tips and guides
- Contributing documentation in other languages
- Updating the documentation itself
  - Getting permission to update the documentation
  - Our style guide
  - How we manage community updates

**Updating the documentation itself**

Have you found a mistake in the documentation, or do you have a small addition that would be so easy to add yourself rather than asking us to do it? You can update the documentation page directly.

**Getting permission to update the documentation**

Please submit the Atlassian Contributor License Agreement.

**Our style guide**

Please read our short guidelines for authors.

**How we manage community updates**

Here is a quick guide to how we manage community contributions to our documentation and the copyright that applies to the documentation:

- **Monitoring by technical writers.** The Atlassian technical writers monitor the updates to the documentation spaces, using RSS feeds and watching the spaces. If someone makes an update that needs some attention from us, we will make the necessary changes.

- **Wiki permissions.** We use wiki permissions to determine who can edit the documentation spaces. We ask people to sign the Atlassian Contributor License Agreement (ACLA) and submit it to us. That allows us to verify that the applicant is a real person. Then we give them permission to update the documentation.

- **Copyright.** The Atlassian documentation is published under a Creative Commons CC BY license. Specifically, we use a Creative Commons Attribution 2.5 Australia License. This means that anyone can copy, distribute and adapt our documentation provided they acknowledge the source of the documentation. The CC BY license is shown in the footer of every page, so that anyone who contributes to our documentation knows that their contribution falls under the same copyright.
